Counsel for defendants offers in evidence the original drawing referred to by the witness, which is marked "Defendants' Exhibit Working Drawing, Patent 217,838, on Angle Cock" (see Fig. 17); also the tracing referred to by the witness, marked "Defendants' Exhibit Tracing of Working Drawing, Patent 217,838, on Angle Cock."

(Here follows diagram marked p. 1103.)

Cross-examination *de bene esse* by J. SNOWDEN BELL, Esq., of counsel for complainants, reserving objections taken :

X 264 Q. You say that the devices which you tested to prove the operativeness of a device constructed in accordance with patent 217,838 were made "in strict accordance with the patent 217,838." In the tests which you made were they applied to and connected with the other members of an automatic brake system in strict accordance with patent 217,838?

A. They were, as I understand the patent 217,838.

265 X Q. There are two different applications of the device illustrated in patent 217,838, in one of which it is connected with the sections of a two-part hose coupling, and in the other it is applied at a point in the length of a train-pipe having a ported diaphragm; with which of these applications did your experiments accord, or did they accord with both of them?

A. They accorded with both of them—that is to say, 49 of the 50 devices were attached each to one section of a hose coupling, as shown in Fig. 1 of patent, and one of the 50 was arranged in the key of the angle cock, substantially in the manner as shown in Fig. 3—that is to say, the key of the angle cock was provided with a diaphragm O, and the device of patent 217,838 secured to the key, substantially in the manner as shown in Fig. 3.

266 X Q. Was each half section of the several hose couplings provided with one of these devices in accordance with the statement of the patent that "I (the patentee) arrange at such various parts of the air conduit, but by preference at the couplings, relief valves of the kind shown in the drawings," and in accordance with Fig. 4 of the drawings of patent 217,838?

A. As I understand the quotation you refer to, it does not mean that every half section of the hose couplings of the train should be provided with these devices; therefore when I attached the devices of patent 217,838 to the couplings, I arranged one device to each two sections which make one hose coupling, and placed the device in that section which would admit the air from the main reservoir into the device through the aperture A. I did not arrange them as shown in Fig. 4, because if arranged in the manner therein shown, one of the devices would be inoperative, as stated in my testimony-in-chief.

267 X Q. Then as a matter of fact, so far as your application of the device to hose couplings was concerned, such application was *not* in accordance with the only illustration given in the drawings of the application of the device in connection with other members in an automatic brake system, to wit, that shown in Fig. 4, and differed therefrom in the particular that while said Fig. 4 shows the valve device as connected to each half section of the couplings, you only connected it to one of the half sections. This is correct, is it not?

A. So far as concerns Fig. 4, it is correct, but I consider the manner I attached the device to the couplings to be in accordance with the patent, especially so owing to the following quotation:

"The same device *may be applied at any part* of the communicating pipes, *p*, by making therein, across the bore of the pipe, a ported diaphragm O, Fig. 3."

In the arrangement of the device shown in Fig. 3, but one valve device is used, which clearly indicates but one is to be used on each car; therefore, I think I am in strict accordance with the patent in using one device to each two sections of the hose couplings.

1106 All of the last preceding answer, succeeding the word "correct," objected to as not responsive, and a volunteered argument of the witness.

268 X Q. Did you or did you not apply the devices to the couplings in accordance with Fig. 4 of the drawings of patent 217,838, and is not said Fig. 4 the only figure of said drawings in which the devices are shown in connection with a train-pipe, triple valve, auxiliary reservoir and brake-cylinder of an automatic brake system?

A. Pertaining to the first part of your question I did not apply two of the devices to each of the hose couplings as shown in Fig. 4, as I used common sense, and applied the devices to the train-pipe in such manner that they *would* work, and not in a manner that they would *not* work. As to the second part of your question, Fig. 4 is the only figure of the said drawing in which the devices are shown in connection with a train-pipe, *triple valve, auxiliary reservoir and brake-cylinder*.

269 X Q. You also say that one of the 50 valve devices of patent 217,838 which you used, was arranged substantially as shown in Fig. 3 of that patent. Does Fig. 3 show the valve device in or in connection with the key of an angle cock?

A. No, it does not, but it shows it arranged with a ported diaphragm in the pipe, and as arranged in the key of the angle cock it is there also placed in connection with a ported diaphragm.

All of the answer succeeding the word "not" objected to as not responsive, and a volunteered statement.

270 X Q. Does the description of Fig. 3 given in the specification of patent 217,838, state that the valve device is to be used in or in connection with the key of an angle cock?

A. It does not.

271 X Q. Does the specification of patent 217,838, *anywhere* state that the valve device of said patent is to be used in or connected to the key of an angle cock?

A. It does not, so far as I know.

1107 272 X Q. When applying the valve devices of patent 217,838 in accordance with what you understood and understand to be their intended application when attached to hose couplings, you were particularly careful, were you not, to attach them so that they would be on the front coupling section of a train-pipe of each car represented on the rack, that is to say, the section nearest the main air reservoir on the engine?

A. I was.

273 X Q. Do you find any indication in the drawings or instruction in the specification of patent 217,838 that in the application of valve device of said patent to an automatic brake system, it must be placed upon such coupling section, and only upon such coupling section as specified in the last question and answer?

A. The specification states as follows:

"When compressed air enters the valve box by the aperture A from the front portion of the communication pipe, it raises by its pressure the valve E, passes through the holes *d* in the piston D, keeps the valve F closed, and passes out by the passage B¹ and aperture B to the hinder portion as the pipe to charge the auxiliary reservoir, in the usual way."

From this description of the operation it is plain that the valve device must be applied to the train-pipe in such a manner that the compressed air from the storage tank or main reservoir must pass into the device by way of aperture A. From this quotation any one skilled in air brakes, in placing the device in the train-pipe, would arrange it in such a manner that it would operate as set forth in the specification.

I do not find any direct statement in the specification as set forth in your question.

274 X Q. Then as a matter of fact, and regardless of your inferences and conclusions, the specification of patent 217,838 does *not* contain any instruction or direction that the valve devices must be arranged relatively to the main air reservoir in the manner in which you arrange them; this is true, is it not?

1108 A. I do not find any passage in the specification that states that they *must* be placed as I arranged them in making the test, although the specification states:

"The form or construction of the relief valve, its function and operation being substantially retained, may be varied considerably, in so far as it is an element in the described combination, without any material departure from the scope of the invention."

This quotation gives great latitude to the skilled mechanic in the construction or form of the valve, and I think it also gives the skilled mechanic considerable scope for his judgment as to how or where the device would be arranged, so long as the described combination was maintained.

Objection to as not responsive, and an unwarranted and unasked-for statement of the witness, and counsel for complainants protests against and asks the attention of the court to the waste of time caused by the witness in formulating and enunciating arguments in response to questions of fact.

275 X Q. Could not the last preceding question have been truthfully answered by the single word "yes?"

A. It could have, but I think it my duty to the court to point out those parts of the specification wherein it states anything of a nature giving license to a skilled mechanic to use his judgment as to the construction or arrangement of the valve.

In further looking over specification I find the following (page 1, column 2, second paragraph):

"The aperture A of the valve box is seated in the lateral port opening of the *coupling R*, so as to come in the *line* of the *flow* of air through the brake-pipe, hose, and couplings." (The italics are my own.)

This quotation would also indicate that the valves are to be placed in the couplings as I placed them.

Objection and protest continued.

1109 276 X Q. Suggesting to you that your duty to the court will be better complied with if you will refrain from volunteering arguments in reply to questions of fact, and noting that you seem to object to my use of the word "must," I now ask you whether it is not true, as a matter of fact, and regardless of your inferences and conclusions, that the specification of patent 217,838, does *not* contain any instruction or direction whatever that the valve devices are to be located relatively to the main air reservoir in the manner in which you located them. This question calls for and fairly admits of a specific answer, and I will be obliged if you will give one?

A. The specification does not specify how the valve should be placed in relation to the *main air reservoir*, but it certainly does state that the aperture A must be placed so as to come in line of the flow of air through the brake-pipes leading from the main air reservoir, and I think I am justified in stating that the specification plainly implies how the aperture A of the valves are to be placed in the couplings R in reference to the flow of the air through the pipes as set forth in the last preceding quotation.

Objection and protest continued as to all of the answer succeeding the word "reservoir."

277 X Q. Could not cross-question 276 have been truthfully answered in the affirmative?

A. It could not, as I stated in my preceding answer there are instructions in the patent which direct how the valve should be located in regard to the direction in which the air passes through.

278 X Q. Then if X Q. 276 could *not* have been truthfully answered in the affirmative, please quote from patent 217,838 whatever you may choose to call an instruction or direction that the valve

devices are to be located relatively to the main air reservoir in the manner in which you located them?

A. I will quote the following (page 1, column 2, paragraphs 2 and 3):

1110 "The aperture A of the valve box is seated in the lateral port opening of the coupling R, so as to come in the line of the flow of air through the brake-pipe, hose, and couplings."

"The aperture A communicates with the port of the next *half coupling*, and the aperture B leads to the hose and brake-pipe." (The italics are my own.)

From these quotations it is perfectly plain to me, as a skilled air-brake mechanic, and I think would be to any other skilled air-brake mechanic, how to place the relative position of the aperture A in relation to the flow of the air through the train-pipe.

In the last paragraph of the two quoted, it states that the aperture A communicates with the port of the next half coupling, and this is the exact manner in which I had the aperture A of the valve device of patent 217,838 placed in making the tests referred to in my deposition-in-chief.

279 X Q. Do you desire the court to understand that you believe that the quotation made in your last preceding answer is an instruction or direction of the specification of patent 217,838, that the valve devices are to be located relatively to the main air reservoir in the manner in which you located them?

A. I certainly do.

280 X Q. Would not the aperture A "come in the line of the flow of air through the brake-pipe, hose, and couplings," just exactly as much if the valve devices had been located so that the ports B¹ were nearer the main air reservoir than the aperture A, as if they had been located in the manner in which you located them?

A. No, that is not the manner in which I would interpret the meaning of the second paragraph, column 2, page 1.

281 X Q. Would not the aperture A communicate with the port of the next half coupling just as fully if the valve devices had been located with the ports B¹ nearer the main air reservoir than the apertures A, as they would do if they had been located as you located them?

A. That is not the interpretation I would put on the paragraph.

If the two paragraphs were to be interpreted in such a manner as to place the apertures, B, nearest the engine, such an interpretation and location would make the valve device inoperative, and I consider that the common-sense view as to the manner in which the paragraphs are to be interpreted, is that manner in which the valve devices will be operative.

Objected to as not responsive

282 X Q. I did not ask you anything about your "interpretation" of the specification, or of any "paragraph" in it, but *did* ask you a plain question of mechanical fact, wholly separate and apart from the specification. With this explanation I repeat cross-question 281.

A. Literally speaking, I think they would, but when taken as the devices are to be used, and in connection with the elements they are to be used with, I don't think they would, and I base my opinion on the fact that in one way the valve device 217,838 *would be operative*, whereas in the other way they would *not* be operative, and it seems obvious that *the proper way to place them* is the way in which the valve devices would be operative.

283 X Q. I did not ask you anything about the proper way to place the valve devices, and only asked you as to the communication of the aperture A with the port of the next half coupling. In order that you may put yourself clearly on record on this point, I will now ask you to state as a matter of mechanical fact for the information of the court whether the aperture A would not communicate just as fully with the port of the next half coupling if the valve devices were located with the ports B' nearer the reservoir than the aperture A, as they would do if they had been located as you located them?

1112 A. I have stated that they would, literally speaking, but in operation of the device with the other parts it is evident that they are to be located so that the air will pass from the main air reservoir into the device in the proper manner.

284 X Q. You say that they would "literally speaking;" would they not absolutely and unqualifiedly?

A. They would, if nothing else is to be considered in the matter; that is to say, if you just couple up two sections of coupling they would certainly be in communication if the air was admitted from either direction; but this is not the manner in which they are to be coupled when the device is to be in operation in connection with the automatic brake.

285 X Q. The aperture A would communicate just as fully, and communicate no more or no less, with the port of the next half coupling if the devices were coupled in the way in which you think they ought to be, as they would if the devices were coupled in the way in which you think they ought not to be. Is not this undoubtedly the case, as a matter of mechanical fact?

A. I have endeavored to answer the questions pertaining to the subject under discussion in a truthful manner, and in the manner that they should be answered in the light of the description of the device as set forth in the patent; they are the best answers I can give, and as I have, I think, fully answered them I think it would be useless for me to try to answer any more fully, nor can I do so.

The answer is objected to, as not in the slightest degree responsive.

286 X Q. I have not intimated a doubt of your truthfulness in your deposition, and have objected only to your substituting arguments for statements of fact when asked for. As X Q. 285 is a simple question of mechanical fact which it would be absurd to suppose that one having your mechanical qualifications is unable to answer, I shall have to repeat it, and ask you to give a categorical answer?

1113 A. I did answer it substantially in my preceding answer, in which I stated that *they would*, if the couplings were to be coupled together and nothing else considered except as to the aperture A being in communication with the port of the next half coupling.

287 X Q. Would the aperture A be any more or any less in the line of the flow of air through the brake-pipe, hose and couplings, if the devices were located relatively to the main air reservoir, in what you believe to be the proper and operative way of locating them, than if they were located in what you believe to be the improper and inoperative way of locating them?

A. I should say that in the one case they would be in the proper form of the line of the flow of air, and in the other case they would be in an improper form of the flow of air. It is true that in both positions they would be "in the line of the flow of air," but in one case the line of valve devices would be operative and in the other they would not, and I think the quotation from the patent, pertaining to the aperture A being in communication with the port of the next half coupling, undoubtedly conveys the meaning that the aperture A should be arranged as I have stated.

288 X Q. Can you not give a specific answer to X Q. 287?

A. I think I have given a specific answer when I stated that they would not be any more or less in the line of communication,—if you mean that the devices are to be just coupled together without reference to the operativeness of the devices.

289 X Q. In view of the arguments which you have made in your cross-examination, and of the manner in which you located the valve devices of patent 217,838 relatively to the main reservoir in your tests, I presume you will unhesitatingly admit that if said devices were so located in a train line that the passages B¹ would be nearest the main reservoir, so that the passage of air in the train line would be from left to right in the drawing, said devices would not only be wholly inoperative for the purpose provided in
1114 the patent, but would also be fully operative to absolutely destroy the effectiveness and operativeness of the entire brake system. Will you make this admission?

A. My understanding of the device shown in patent 217,838, is, if put in the train-pipe line with the aperture B towards the end so that the air in its passage from the main drum would first pass through the aperture B, instead of A, this air would act on the piston D so as to open the port C and prevent the brakes from being charged, and in this sense, it would destroy the operativeness of the automatic brake; but no skilled mechanic in air-brake practice would apply the devices of patent 217,838 in such a manner; on the contrary, he would apply it in a manner to make the device operative, and in such a way as to admit the air from the main reservoir, first through the aperture A as it passed to the device of the said patent. I think a man would be utterly devoid of sense to place a device in relative position to other parts in such a manner that it would be inoperative, whereas by use of common judgment he could arrange it so it would be operative, as I have done.

Answer objected to, as not responsive, and embodying a volunteered argument of the witness.

290 X Q. Will you, or will you not, unqualifiedly admit that if the devices of patent 217,838 were so located in a train line, that the passages B¹ would be nearest the main reservoir, so that the passage of air in the train line would be from left to right in the drawing, said devices would not only be wholly inoperative for the purpose provided in the patent, but would also be fully operative to absolutely destroy the effectiveness and operativeness of the entire brake system?

A. I will, and I did so admit in my preceding answer, when I stated "it would destroy the operativeness of the automatic brake."

Adjourned to meet tomorrow April 6, 1894, at 10 o'clock a. m.

FRIDAY, April 6, 1894.

Met pursuant to adjournment.

Present: Counsel as before.

1115 Cross-examination of Mr. G. A. BOYDEN resumed:

291 X Q. It therefore necessarily follows, does it not, that it would be mechanically impossible for the devices of patent 217,838 to be operative in an automatic air-brake system, unless each of these devices was so located in the line of train-pipe relatively to the main air reservoir, that the aperture A would be nearer the main reservoir than the passage B¹, or, in other words, the aperture A would always be nearest the front of the car?

A. My understanding of the operation of the device is that the aperture A must be located so as to receive the air from the main air reservoir on the engine, and if it is placed in the position with the aperture B towards the engine, then the device would be inoperative.

292 X Q. The statement which I made in X Q. 291 is then entirely correct, is it not?

A. I consider that it is, but in order that my answer should not be misconstrued in any way, I made the explanation set forth in my preceding answer.

293 X Q. Do you think there is any risk of being misconstrued in admitting unqualifiedly the correctness of the statement, when you consider it to be true, and have no reason to qualify it in any particular?

A. No, I do not, provided my answer is always connected with the question.

294 X Q. You will also unqualifiedly admit, will you not, that if a half coupling on the train-pipe of a car having attached one of the devices of patent 217,838 was connected to the half coupling of an adjacent car, also having one of these devices attached, as indicated in Fig. 4 of patent 217,838, said devices would not only be wholly inoperative for the purposes provided in the patent, but would be operative to absolutely destroy the effectiveness and operativeness of the entire brake system?

A. I will admit that such is the case, when the devices are
1116 placed in the positions you have referred to in your question,
and I have so testified in my deposition-in-chief, in answer
to question 262.

295 X Q. You will also unqualifiedly admit, will you not, that if
the train-pipe of a railroad car was fitted with one of the devices of
patent 217,838, it would be necessary to turn the car after each run,
in order that the aperture A should always be in advance or towards
the engine?

A. I will admit that such would be the case, that is to say, if
there is no other means provided, the car would have to be turned
around, so that the aperture A would be in position to receive the
air from the main reservoir on the engine.

296 X Q. As a skilled air-brake constructor and president of the
corporation defendant, is it your opinion that this or any other de-
vice which required that a car would have to be turned after every
run, in order that its air-brake apparatus should be operative when
moving in the opposite direction, would be a usefully operative de-
vice in an automatic air brake system, or would be accepted as such
by any sane railroad man?

A. As a skilled air-brake constructor, my opinion is that this
device or any other that would require the car to be turned around
before the device could be used, would not be practicable at all in
railroad service; and further, I don't think any sane railroad man
would apply a device that would require a car to be turned before
the device could be operative; and, I also consider, as a skilled air-
brake constructor, I would be insane to apply such a device, or any
device to a car that would not be operative, but as a skilled air-
brake mechanic I would apply the device to the car in such a way
that it would be operative, and I have shown one way wherein I
have located the device of patent 217,838 in the key of the cut-off
cock, by which the device would be made operative without revers-
ing the position of the car.

The latter portion of the answer, commencing with the
1117 word "but" objected to as not in the slightest degree re-
sponsive, and a volunteered statement.

297 X Q. I am not asking you anything about what you or any-
body else might invent to overcome the obvious practical inopera-
tiveness of the device of patent 217,838, and my question was
simply directed to that device as described and shown in that pat-
ent, and not to some other or different construction. Am I or not
correct in understanding you to admit that you do not consider the
device described and shown in patent 217,838 to be a usefully op-
erative one in an automatic air-brake system, by reason of the fact
that with such device the car must be turned after each run, in order
to enable its brake apparatus to be operative at all when running in
the opposite direction?

A. You are correct in understanding me to admit that the device
shown in patent 217,838 to be operative must admit the air to the
valve device through the aperture A, and if it was placed in a posi-

tion that this would not be the case, the device would be inoperative. I think, from the following quotation from the patent, that it is obvious that the inventor intended the device to be put in the train-pipe in a certain way, that is to say, with the aperture A in a position to receive the air from the storage reservoir on the locomotive. The quotation is as follows (page 1, column 2, 4th paragraph):

"When compressed air enters the valve box by the aperture A from the *front portion of the communicating pipe, &c., &c.*" (The italics are my own.)

Answer objected to as not in the least degree responsive.

297 X Q. repeated.

A. You are correct in understanding me to admit that the device as shown in the patent would be inoperative by reason of the fact that the car would have to be turned around to make the device operative, provided the car was not in the proper position to receive the air, that is to pass the air into the device through the aperture A.

298 X Q. If the car was in proper position for the device to be operative when moving in one direction, it would necessarily be in position for the device to be inoperative and destroy the effectiveness of the brake system when running in the opposite direction, would it not?

A. It would, if the air from the engine was also coming from the opposite direction.

299 X Q. I mean of course that in each direction of motion the engine was placed at the head of the train, as is usual in running a train. With this explanation, you would answer X Q. 298 unqualifiedly in the affirmative, would you not?

A. I would.

300 X Q. Coming now to this novel angle-cock device which you have presented, and which I understand you to admit is not shown in the drawing or described in the specification of patent 217,838. From your knowledge as an expert of the state of the art, was an angle cock having a ported diaphragm in its key ever known or used prior to its being devised by you in the construction which you have here presented?

A. My opinion is no such cock was ever used or devised before.

301 X Q. Such a device then was not, in your opinion, known in the art at the date of the patent 217,838?

A. So far as I know, it was not.

302 X Q. Was a valve device similar to that of patent 217,838, connected to the key of an angle cock and having its aperture A communicating with a port in a diaphragm in said key as, or substantially as, in the angle-cock construction here presented by you, known in the art at the date of the patent 217,838?

A. It was not, so far as I understand.

303 X Q. Such a device or construction as is recited in the last preceding question would attain the new and useful result of over-

coming, in your opinion, the practical inoperativeness of the
1119 device described and shown in patent 217,838 due to the fact
that with the device described and shown in patent 217,838
it is necessary to turn the car whenever its direction of motion is to
be reversed. This is the fact, is it not?

A. It would.

304 X Q. In view of your familiarity with letters patent, and
your experience as a solicitor of patents, testified to in your original
deposition, please state whether or not, by reason of the novelty and
utility of the angle-cock construction, recited in X Q. 302, and
presented by you, said construction would involve invention, and
be entitled to the protection of letters patent?

A. My opinion is that it might be.

305 X Q. It is a fact, is it not, that long prior to the institution of
this suit, you yourself recognized the obvious practical inoperative-
ness of the device of patent 217,838, and invented and patented
another appliance of that character with a view to obviating such
inoperativeness; such invention being the subject of your letters
patent No. 404,768, dated June 4th, 1889?

A. It is, and I also designed and used valve devices substantially
like that of the patent 217,838, that is to say, a device having a port
and valve mechanism to discharge the air from the train-pipe at
each car, to quicken the consecutive action of the brakes which did
not require a cock to reverse it, as they did not require reversal.
These valves I applied to a train, which was tried on the B. & O.
railroad, and worked entirely satisfactory; for this latter valve I
do not remember of ever applying for a patent.

306 X Q. In making the valve devices similar to those of patent
217,838, with which you experimented, on what scale did you make
them, relatively to the drawing of the patent. I mean of course
the devices with which you made the test referred to in your depo-
sition-in-chief.

A. About twice as large, that is to say, I could not follow the
exact relative scale in the patent 217,838 of the device shown in
Fig. 1.

1120 307 X Q. Is it not a fact that the springs in these devices
which correspond with the springs *e*, of patent 217,838, are
not of as great dimensions as those shown in the patent, that is
to say, that they are not increased proportionately to those of the
patent?

A. I cannot answer that question, because there is no means to
ascertain the tension of the spring *e* in the patent.

308 X Q. And you do not therefore know what tension should be
exerted by these springs to be in proper accordance with the patent,
do you?

A. They should exert enough tension to just keep the valve E
seated, or in its relative position as shown in Fig. 1.

309 X Q. All the tests which you made with these devices were
made on the rack at your works, were they not?

A. They were.

310 X Q. How many tests did you make, and when?

A. I made various tests, commencing with one valve, then 12, then 25, then 50. It would be impossible for me to state how many times I tried them. They were made since the first of this year.

311 X Q. Were you assisted in these tests by anybody else but Mr. Gwinn?

A. No; of course the workmen were present, who would do the manual work under instructions from Mr. Gwinn or me.

312 X Q. Did you make any record of the results of these tests, and if so, can you produce them?

A. No, I made no record of the tests.

313 X Q. The record shows that in your answer to Q. 247, you originally said: "I then graduated the brakes and found that they graduated the same as though the new valve element were not employed." You afterwards amended this answer by cancelling the words "the same as though the new valve element were not employed," so that the matter as originally stated by you now reads: "I then graduated the brakes and found that they all graduated in the regular order."

1121 Did you find that they graduated "the same as though the new valve element were not employed," and if not, what difference in graduation did you observe?

A. The reason I changed the wording of the sentence you refer to was, that I did not try how the brakes graduated without the device, therefore the manner in which I first stated it was not correct, as I did not try the brakes in the graduation application without the valve devices of patent 217,838.

314 X Q. Then as a matter of fact you do not know and cannot say whether or not, when using these new valve elements of patent 217,838, the brakes graduated "the same as though the new valve element were not employed?"

A. I cannot say. What I wished to ascertain was, could the brakes be graduated without producing a quick action, and not as to the *degree of proficiency* of the graduating application.

315 X Q. Is it not the fact that in every application of the brakes which you made the valves F opened and released air from the train-pipe at points adjacent to the respective triple valves?

A. No, it is not a fact. The valves did not open when the graduation application was made, but did open when a *quick* application of the brakes was made.

316 X Q. If the valves F did not open when a graduation was made, how were you able to effect a reduction of train-pipe pressure in that part of the train-pipe in rear of the first appliance in which the valve F did not open?

A. Owing to the fact that the pistons D are about one sixty-fourth of an inch smaller in diameter than the bore of the cylinder in which the piston-D move. In making the graduation application of the brakes, the air from the rear portion of the train passes to the front portion by passing around the piston, D, or through the space between the piston and the cylinder.

317 X Q. Do you find any warrant whatever in the specification

or drawings of patent 217,838 for making the piston D one
 1122 sixty-fourth of an inch smaller than the cylinder in which
 it works, or for making any provision whatever for leakage
 around said piston. If so, please indicate specifically by reference
 to the patent, what you consider to be your warrant for such a va-
 riation from it?

A. I find no specific statement as to the relative size of the piston
 in reference to the cylinder in which it works; however, my war-
 rant for using my judgment in constructing the device, I take from
 the following quotation (page 2, column 1, paragraph 2.)

"The form or construction, of the relief valve, its function and
 operation being substantially retained, *may be varied considerably*, in
 so far as it is an element in the described combination, without any
 material departure from the scope of the invention." (The italics
 are my own.)

318 X Q. Is it possible that you pretend, or desire the court to
 understand, that you believe the quotation you have made from
 the patent approaches in the slightest degree to a warrant or in-
 struction to a mechanic to make provision for leakage around the
 piston D, in constructing the device of patent 217,838?

A. I do, and I wish the court to understand that that is the way
 I interpret the specification.

319 X Q. Did you note, and can you state, the time required for
 effecting the application of the brakes by graduation, when using
 the devices of patent 217,838, modified as you have stated by the
 provision of a leakage space around the piston D?

A. I did not note, or take the time for graduation applications
 when the devices of patent 217,838 were used.

320 X Q. You are then unable to state whether or not the applica-
 tion of the brakes was made when graduating in the time that would
 be required to be usefully operative for practical purposes?

A. I am. As I before stated I was not experimenting to ascer-
 tain the *degree of efficiency* of the device, or with a view to put it in
 the *best order* or condition for practical purposes; I merely
 1123 wished to ascertain if the device would quicken the action of
 the brakes, graduate and release them, without destroying
 either of the operations.

321 X Q. Now, as to release, which, as you will probably recog-
 nize, is a matter of some little importance, as to useful operativeness
 in practical service. You say, "I then released the brakes in the
 regular manner, by admitting air to the train-pipe, and the brakes
 all released."

Did you note, and can you state, how long it took them to release?

A. I did not time the release, and therefore cannot state the exact
 time, although the brakes released in about the same manner that
 the brakes usually release when the rack is equipped with our regu-
 lar quick-action valve.

322 X Q. I am asking you only as to the *time* of release, and
 nothing as to the manner. Is it not the fact that the time of release
 was greatly longer than under ordinary conditions, and much too
 long to comply with the requirements of practical service?

A. No, it was not a great deal longer, if any, nor was it of such a duration of time that it would be impracticable in operation in service.

323 X Q. Did you time the release?

A. No, I did not.

324 X Q. Now as to charging. You say, "I then charged the brakes with 70 pounds air pressure." How long did it take you to charge the train?

A. I did not time it.

325 X Q. Did it not take, as far as you observed, a materially longer time to charge the train with 70 pounds of air pressure than is the case in usual and correct practice?

A. No, it didn't take a *materially* longer time, but my recollection is that it was somewhat longer, although I didn't take any time.

326 X Q. You say, referring to the device of patent 217,838, that it "does not obstruct the feeding or charging process." Is it not obvious on inspection to any mechanic that the presence in a train line of a series of spring-pressed valves, each of which must be unseated, in feeding or charging, necessarily must obstruct that process?

A. I should say it was if the springs are of such a tension that it required a considerable preponderance of pressure to overcome the spring, but in the device shown in patent 217,838, I can see no reason or advantage in having a spring of any greater tension than is just sufficient to move the valve to its seat. My opinion, however, is that the device would work equally well if no spring was employed at all, simply because when the air pressure moves from aperture B to A, that pressure would close the valve E.

All of the answer succeeding the word "was" objected to as not responsive.

327 X Q. Wholly regardless of the *degree* of tension of the springs, is it not self-evident that the presence in the train line of a series of valves which must be unseated in feeding or charging, must necessarily affect that operation?

A. No.

328 X Q. Then am I to understand that you are under the impression that the feeding and charging of the train line could be performed just as well and just as quickly when provided with a series of the appliances of patent 217,838, as could be done in the ordinary train line?

A. My opinion is it would take some longer time, just to what degree I can't say, but the delay would not be sufficient to interfere with the practical operation, or charging of the brakes.

329 X Q. That delay, however the extent of which you do not know, would be due altogether, would it not, to the obstruction of the train line by the devices of patent 217,838. If you shall say that it would not be, please state what you think it would be due to.

A. I have stated the charging would be somewhat slower, but if I was going to make the devices, using such judgment as the patent licenses me to use, I should make a device in accord-

ance with that patent and would charge the train and brakes for all practical purposes just as quickly as through the devices were not used in the train-pipe. The delay, however, which I have referred to, in some of my preceding answers, would be caused by the devices as shown in patent 217,838.

330 X Q. Could not the last question have been truthfully answered by the single word "yes," without the slightest qualification whatever?

A. It could have, but I thought it was proper for me to express my opinion on the matter under discussion.

331 X Q. Did the opinion which you expressed, in the slightest degree qualify a direct affirmative answer to the question?

A. It does, to the extent that I was making devices under the guidance of the patent, and using my judgment, as a skilled air-brake mechanic.

332 X Q. Were you asked anything about the probable results of your efforts to accomplish the feat of making the passage of air through an obstructed pipe as easy and rapid as through an unobstructed one?

A. No, I was not asked for my opinion.

333 X Q. You say that you charged the brakes with 70 pounds pressure, and "applied for an emergency application." How did you manage to apply for an emergency application, if, as you state, the triple valves which you used were "plain triple valves," and "of a character which will not produce quick action"?

A. I threw the handle of the engineers' valve to that position in which the train-pipe air would be discharged fully, and let it remain in that position until all the air was discharged from the said train-pipe.

334 X Q. I presume you mean by that that you manipulated the engineers' valve in such a way that a quick-action or emergency application would have been effected if you had been using quick-action triple valves. Am I right?

A. In a sense, you are, that is to say, that you could place the engineers' valve in the emergency-application position, and
1126 leave it remain open; but in producing a "quick action" with the quick-action valves as now generally used in practice, the engineers' valve is manipulated sometimes in such a manner that the train-pipe is first discharged of about 20 to 30 pounds pressure, and then the engineers' valve is blanked. Of these two ways, I used the first, that is to say, I placed the engineers' valve in full open position, and let it remain there until the pressure had equalized in the 50th brake-cylinder and auxiliary reservoir.

335 X Q. You say I am right in a sense. Am I not right in every sense, and if not, in what sense am I wrong?

A. No, you are not right, as I understand the matter. I have stated that there are two ways of manipulating the engineers' valve in producing quick action. You asked me in question 333, "How did you manage to apply for an emergency application." I replied by stating that I threw the handle of the engineers' valve in a certain position. You then asked me in question 334 if I put it in that

position for a quick-action or emergency application, when the quick-action triple valves were used. I then stated in a sense you are right, meaning by that, that I did place the engineers' valve in one of the positions, and held it there, that is used in producing emergency application of the quick-acting valves now in use. That is what I meant by "in a sense."

336 X Q. X Q. 334 did not say a word about "the position" of the engineers' valve, and simply asked you whether or not "you manipulated the engineers' valve in such a way that a quick-action or emergency application would have been effected if you had been using quick-action triple valves." Did you or did you not do so?

A. I did so.

337 X Q. Then whether there are two, or two hundred, or two thousand ways of manipulating the engineers' valve to effect a quick-action or emergency application, I was right in *every* sense, was I not, in the statement made in X Q. 334?

1127 A. You were. Had I understood your question at first as fully as I did when you repeated it, I would have made the answer that I did when you repeated it.

338 X Q. After you made, in your test, an application of the brakes in which the valves F opened the release port C, the pistons D dropped below the shoulders s, and there was then an open communication between the train-pipe and the atmosphere through each of the appliances of patent 217,838. This is a fact, is it not?

A. As I understand your question, there was.

339 X Q. How was it that when you attempted to recharge the train line, the air did not escape therefrom through these open communications to the atmosphere?

A. Because when the air was again admitted to the train-pipe from the storage reservoir, it passed into the aperture A and acted on the piston D, thereby moving the piston and valve F to the closed position, as shown in Figs. 1 and 3.

340 X Q. Did not the first portion of the air which was admitted to each of the appliances when recharging, escape through the then open communication, before the piston closed the valve?

A. I did not observe that any escaped. All the valves promptly closed throughout the train.

341 X Q. Are you prepared to say, and do you say, that the first portion of the air admitted to each of the appliances in recharging did not escape through the then open port C before the piston closed the valve F on that port?

A. I am prepared to say that if there was any escape, it was of such a small quantity, that it was not appreciable, as in making all the tests, the valves or devices of patent 217,838, closed so promptly that all the brakes were released.

342 X Q. You do not, however, know how much air was wasted in this way; how much delay in charging, and how much delay in releasing the brakes was involved. This is a fact, is it not?

1128 A. If there was any waste of air, or delay in charging and releasing the brakes, it was of such a nature that it was not

perceptible. I did not experiment to ascertain just what these conditions were, if the conditions existed.

Answer objected to, as not responsive.

X Q. 342 repeated, and a categorical answer requested.

A. I do not, but if there was such waste and delay as you mention, they were of such a nature that it didn't interfere with the practical operation.

All of the answer succeeding the word "not" objected to, as not responsive, and further as incompetent, in view of the witness' admissions that he did not take note of the quantity of air wasted, or of the time required for charging and releasing.

343 X Q. Did the tests which you made with the device of patent 217,838, demonstrate that said device was practically operative in anywise for admitting air in the application of the brake directly from the main air pipe to the brake-cylinder?

A. They did not.

344 X Q. Did the tests which you made with the device of patent 217,838, demonstrate that said device was in anywise practically operative to admit air from the auxiliary reservoir to the brake-cylinder by preliminary traverse of the triple-valve piston, and to admit air directly from the main air pipe to the brake-cylinder by a further traverse of the triple-valve piston?

A. They did not.

345 X Q. Did the tests which you made with the device of patent 217,838, demonstrate that said device was practically operative to a degree sufficient to warrant you or any other capable air-brake constructor in advising its adoption in practical railway service?

A. The tests demonstrated that the device would quicken the action of the brakes; and they demonstrated to my mind, as I think they would to any one who is skilled in air brakes, that the device of patent 217,838 could be so arranged and modified to suit the automatic air brake as to make it just as efficient a brake as those now in general use, and one that could be recommended to railroad officials for practical use.

Answer objected to as not responsive.

346 X Q. X Q. 345 repeated.

A. The results produced by the devices of patent 217,838, as I tried them, were not of an efficiency that would justify me in recommending the use of the devices to railroad officials.

347 X Q. Did the tests which you made with the device of patent 217,838 demonstrate that said device was practically operative to such a degree as to lead you to believe that it would be acceptable to, and accepted by, any competent railroad official, for use in practical railroad air-brake service?

A. The tests I made with the device of patent 217,838 demonstrates that the device, as I made them, was not practically operative to be used in service; but they demonstrated that the device of patent 217,838 could be so modified that it would practically be oper-

ative in railroad service. As to being able to get railroad officials to adopt it, that is something I cannot say, as I might be able, then again I might not.

348 X Q. I am not asking you anything about what possibly might be the case if the device was modified, as it is quite evident that in the light of subsequent invention, it might be modified so materially as possibly to be converted into something that was practically operative. I am, however, asking you as an expert, whether in your opinion the tests made by you demonstrated that the device as it is, was practically operative to such a degree as would lead you to believe that a competent railroad official would accept it for practical service on *its* road. Please let me have your opinion on this point.

A. My opinion is that the device, *as I used it*, would not be acceptable to railroad officials, for practical use.

Counsel for complainants now closes the cross-examination of the witness, and asks of counsel for defendants upon the record whether or not he will consent, first, that a repetition of the 1130 experiments recited by the witness in his deposition-in-chief shall be made by him in the presence of complainants' counsel and experts, at such early day as may be suitable to the engagements of both counsel; and, second, whether he will furnish to complainants' counsel the 50 valve devices of patent 217,838, with which the witness' tests were made, in order that the complainants may make tests thereof upon their own testing rack.

Counsel for defendants states that before making answer to the request which counsel for complainants has made, he desires time to consult with the principal counsel in the case, and states that he will communicate with the counsel who is out of the city, and will make a definite answer as soon as he shall be advised by the principal counsel, which will probably be by the 11th day of April.

Counsel for complainants will be obliged if defendants' counsel will advise him by wire of his decision in the matter, in order that if a repetition of the experiments is to be made, it may be done as early as practicable, and in view of the engagements of complainants' counsel, it is doubtful whether he would be able to attend for the purpose except on some day in the latter part of next week.

Counsel for defendants replies that he will wire counsel for complainants his answer within the time already named.

GEORGE A. BOYDEN.

LEVEN J. GWINN, a witness produced on behalf of the defendants, having been duly sworn, deposes and says, in answers to interrogatories propounded to him by Charles B. Mann, Esq., of counsel for defendants, as follows, to wit:

1133 1 Q. What is your name, age, residence and occupation?

A. Leven J. Gwinn; 31 years old; Baltimore; machinist and mechanical draftsman.

2 Q. Please look at the drawing of patent granted to George Westinghouse, Jr., July 22, 1879, No. 217,838, and state what part you

took in making working drawings for the construction of the device shown therein?

A. I made all the detail working drawings and sketches necessary for constructing the devices shown therein from the original drawing made by George A. Boyden, which he made from drawings of patent No. 217,838, in my presence. I also made two drawings from same original drawing to be used as exhibits in taking this testimony; one being a device shown in patent No. 217,838, and the other being the same device attached to the key of an angle cock. I identify this drawing, marked "Defendants' Exhibit Copy of Working Drawing, Patent 217,838, July 22, 1879," as the drawing I made from the original drawing made by Mr. Boyden. Here is another drawing I identify, marked "Defendants' Exhibit Tracing of Working Drawing, Patent 217,838, on Angle Cock."

3 Q. Please state whether or not the drawing marked "Defendants' Exhibit Copy of Working Drawing, Patent No. 217,838, July 22, 1879," (Fig. 16,) shows the same construction as that of Fig. 1 in the drawing of patent 217,838? (See Fig. 15.)

(Here follows diagram marked p. 1132.)

A. It does show the same construction.

4 Q. Please state what steps were taken by Mr. Boyden's orders to make devices like that shown in patent No. 217,838?

A. I was ordered to have patterns made, and to get castings made off of same, and to fit up one or two of the devices or relief valves, shown in Westinghouse patent 217,838, which I did. I was then ordered to make a dozen more, and finally 50 of them were made.

5 Q. State whether or not the devices which you referred to as made in accordance with patent 217,838, were tested?

1134 A. They were tested. They were tested on a test-rack in the Boyden Brake Company's shops. This rack has 50 complete automatic air brakes on it, consisting of 50 auxiliary reservoirs, brake-cylinders and plain triple valves, with engineers' valve, gauges, and about 1,900 feet of inch and a quarter train-pipe, with angle cocks, str-ight cut-out cocks, hose and couplings, and an air pump or compressor, and other necessities pertaining to a test-rack for making air-brake tests. 49 of the devices made from patent 217,838 were each attached to one half section of hose couplings throughout the train, and one was attached to the key of an angle cock in a vertical position with the relief or discharge port C, downwards.

6 Q. Briefly describe the tests that were made on that test-rack, to ascertain the operativeness of the devices constructed according to patent 217,838?

A. We proceeded to test, by placing the engineers' valve in full release position; we then started the air compressor, charging all the auxiliary reservoirs and train pipe to 70 pounds pressure; then by placing the engineers' valve handle in the graduating position and gradually reducing the train-pipe pressure, putting about 20 pounds of air in the brake-cylinder. The 50 relief valves or devices

1132

did not discharge any air during this application of the brake. We then placed the engineers' valve handle on the lap or blank position, the air holding the brakes in the applied position. We then placed the engineers' valve handle in full release position to release the brakes, and recharge the auxiliary reservoirs and train-pipe to 70 pounds pressure. We then placed the engineers' valve handle in a quick action or full emergency position, suddenly discharging the train-pipe air at the engineers' valve, thereby causing the brakes to take a quick action and equalizing in the 50th brake-cylinder and auxiliary reservoir at 45 pounds. We then released the brakes by placing the engineers' valve in full release position, and recharging the auxiliary reservoirs and train-pipe to 70 pounds pressure, and uncoupling the hose couplings in train-pipe at 1135 the 25th brake, representing a train breaking in two; the train-pipe air being suddenly reduced at that point, causing the relief valves on the twenty-five rear couplings to uncover discharge ports C to the atmosphere and discharging a portion of the air therefrom, causing the rear 25 brakes to take a quick action, and the 25 brakes nearest the engine to take a full service application. The 50th brake-cylinder and auxiliary reservoir and the first, equalizing at 45 pounds. We then took off all the relief valves and replaced the spiders and caps to hose couplings, thereby making them as usual hose couplings, and recharged the auxiliary reservoirs and train-pipe to 70 pounds pressure. We then placed the engineers' valve in the quick-action position, or full emergency position, and suddenly discharging the train-pipe air, the brakes applied, but not with a quick action, they equalized at 45 pounds in the 50th brake-cylinder and auxiliary reservoir.

7 Q. Please state what you mean by the expressing "causing the brakes to take a quick action."

A. I mean that discharging the train-pipe air suddenly, caused the brakes to move out or apply quickly.

8 Q. Please state, as near as you can, the time that was required in applying the brakes when the device of patent 217,838 was used, and the time required in applying the brakes when that device was not used.

A. In applying the brakes when device 217,838 was used, the quickest time, from the movement of the engineers' valve handle until the 50th brake-cylinder and auxiliary reservoir equalized, was eight seconds; when applying the brakes while devices 217,838 were not used, the quickest time from the movement of the engineers' valve handle until the 50th brake-cylinder and auxiliary reservoir equalized, was 30 seconds.

9 Q. State what particular position the valve devices of patent 217,838 had in making the tests which you have described.

A. 49 of them were applied in a horizontal position, and one was applied in a vertical position, with the relief or discharge port C downward.

1136 10 Q. As you are familiar with air brakes, please state what particular position the valve device of patent 217,838

should have, in your opinion, in order to get the best operative results.

Objected to, as incompetent, it not having been shown that the witness is familiar with air brakes, or capable of forming an opinion intelligently as to the best operative results of the devices connected therewith.

A. I have been employed with the Boyden Air Brake Company for the past five years, as a machinist, and mechanical draftsman; am at present holding a position with the said company as general foreman. I have been sent by the Boyden Brake Company several times to superintend the application of air brakes to freight cars and to locomotives on railroads at points distant from Baltimore; I have also been sent by them to look after complaints of brakes not working right, or being out of order, from various causes, all of which I have replaced in working order.

In answer to your question, my opinion is, that the device should be applied in a vertical position, with relief port C downward, to prevent dirt and foreign substances getting therein.

Adjourned to Saturday, April 7, 1894, at 10 a. m.

SATURDAY, April 7, 1894.

Met pursuant to adjournment.

Present: Counsel as before.

Direct examination of Mr. L. J. GWINN resumed:

A. (Resuming:) This position also ensures that the relief port C will be closed by the gravity of piston D and valve F when starting to charge the train-pipe with air.

11 Q. Please state whether or not the tests Mr. Boyden and you made on the test-rack with devices constructed according to patent 217,838, developed any difficulty that suggested said devices were inoperative.

1137 A. No, there was nothing occurred during the tests that suggested to me that the devices were inoperative; to the contrary, they all operated as I expected them to operate, and as I constructed them to operate.

Cross-examination by J. SNOWDEN BELL, Esq., counsel for complainants:

12 X Q. Did you personally do the turning, boring and other machine work necessary to fit up the 50 devices of patent 217,838, with which the tests were made, or was this done by a machinist working under your orders as general foreman of the Boyden Brake Company?

A. It was done under my orders, as foreman of the Boyden Brake Company, by a machinist and workman.

13 X Q. I notice that the original working drawing which you say was made by Mr. Boyden, marked "Defendants' Exhibit Working Drawing, Patent 217,838, on Angle Cock," shows the piston to

be about one thirty-second of an inch smaller than the bore of the casing in which it fits, so as to leave a space of about one sixty-fourth of an inch all around the piston between its periphery and the bore of the casing in which it fits; this is a fact, is it not?

A. The drawing does show the piston about one thirty-second smaller than the bore.

14 X Q. Were the 50 devices of patent 217,838, with which the tests were made, fitted up in accordance with the working drawing in the particulars stated in the last question; that is to say, with their pistons (the pistons D of the patent) about one thirty-second of an inch smaller than the bore of the casings in which they were?

A. The devices were fitted up with the pistons about a sixty-fourth smaller than the bore of the casing in which they worked.

15 X Q. Why did you not follow the original drawings and make them about one thirty-second of an inch smaller as shown in said drawing?

1138 A. Because in putting the line in the drawing, there was no particular measurement made, the lines were put in by the eye, intending them to be about one sixty-fourth smaller than the bore.

So much of the answer as relates to what was the intention in making the drawing objected to as incompetent, for the reason that the witness has testified that the drawing was made not by himself but by Mr. Boyden.

16 X Q. Did Mr. Boyden instruct you to make the pistons smaller than the bores of the casings in which they worked; and if so, how much smaller did he tell you to make them?

A. Mr. Boyden did instruct me to make the pistons one sixty-fourth of an inch smaller than the bore of the casing.

17 X Q. You say that Mr. Boyden made this original drawing in your presence from the drawings of patent 217,838. Do the drawings of patent 217,838 show the piston D as being smaller than the bore of the casing in which it fits; that is to say, do they show any space whatever between the periphery of the piston and the bore of the casing?

Counsel for defendants objects to the question as being wholly immaterial; the drawing in the patent not being a working drawing.

To which complainants' counsel replies that the question is intended to test the accuracy of the statement that the original drawing in evidence was made from the drawing in the patent.

A. The drawing of patent 217,838 does not show any space between piston and bore of casing.

18 X Q. Does the drawing of patent 217,838 show an angle cock, or show a valve device connected to an angle cock?

A. It does not.

19 X Q. Does the specification of patent 217,838 instruct that the

1139 piston D is to be made smaller than the bore of the casing in which it works, or that any space is to be provided for the passage of air around said piston?

A. I cannot say, as I have not carefully read the specification.

20 X Q. In making the drawing "Defendants' Exhibit Copy of Working Drawing, Patent 217,838, July 22, 1879," and the tracing "Defendants' Exhibit Tracing of Working Drawing, Patent 217,838, on Angle Cock," why did you not make said drawing and tracing correspond with the original drawing, that is to say, by showing on them the piston as about one thirty-second of an inch smaller than the bore of the casing in which it works, as is shown in said original drawing?

A. If the tracing does not show the piston smaller, it was purely a mistake on my part, as I made the tracing hurriedly, and leaving out the lines showing piston smaller than bore by mistake, or oversight.

21 X Q. It is a fact, is it not, that the tracing *does not* show the piston as about one thirty-second of an inch smaller than the bore as the original working drawing does, but shows it as closely fitting in the bore, just as the patent drawings do?

A. It is a fact that the piston shown in tracing does not fit loose in bore of casing.

22 X Q. You mean then to answer the last preceding question specifically in the affirmative, and could have truthfully answered that question by the word "yes"? This is a fact is it not?

A. I could have answered the last preceding question with the single word "yes."

23 X Q. And it is also true, is it not, that the drawing "Defendants' Exhibit Working Drawing, Patent No. 217,838, July 22, 1879," does not correspond with the original drawing in showing the piston as about one thirty-second of an inch smaller than the bore of the casing in which it works, but shows it as closely fitting in the bore just as the patent drawings show it?

A. Yes, it does.

1140 24 X Q. Was this difference between the drawing last referred to and the original working drawing also a matter of oversight on your part?

A. It was.

24 X Q. Were you instructed for what reason you were to make the pistons of the devices which you were fitting up one sixty-fourth of an inch smaller than the bore of the casings in which they were to work?

A. I was not.

26 X Q. From your experience as a mechanic skilled in air brakes, please state whether or not it would be possible to make a graduated application of the brakes when using the device of patent 217,838, if the pistons D are made to fit the bore of the casing in which they work as shown in the drawings of the patent?

A. My opinion is that you could make a graduated application with the piston D fitting closely to the casing.

27 X Q. Did you ever try to do so?

A. I have tried to do so.

28 X Q. Did you succeed?

A. I did.

29 X Q. How long did it take to make the application under such circumstances?

A. That I could not say, as I did not time the application.

30 X Q. In the tests made by Mr. Boyden with these devices, at which you assisted, did you make any note of the time required for charging, the time required for releasing, or the time required for making a graduated application?

A. I did not.

31 X Q. And I presume that you are unable to state the time required for either of the operations specified in the last preceding question?

A. I am unable to state the time.

32 X Q. As a mechanic skilled in air brakes, please state whether or not you consider the device of patent 217,838 to be practically operative to such an extent that it would be acceptable to, and accepted by, any competent railroad man for regular service on his road?

A. I do.

33 X Q. In this particular then, you do not agree with Mr. Boyden, do you, as he states that in his opinion it would not be acceptable to railroad officials for practical use?

A. I don't agree with Mr. Boyden in that respect.

LEVEN J. GWINN.

GEORGE WESTINGHOUSE, JR., and THE WEST-
INGHOUSE AIR BRAKE COMPANY

vs.

BOYDEN POWER BRAKE CO.; GEORGE A. BOY-
den, President; Charles B. Mann, Secre-
tary, and William Whitridge, Treasurer.

In Equity. No. 321.

Notice to Counsel for Complainants.

Counsel for defendants, referring to the request made on the record by counsel for complainants, Friday, April 6th, 1894, asking for a repetition in the presence of complainants' experts and their counsel, of the experiments testified to by Mr. Boyden, and which were made by him and Mr. Gwinn for the purpose of ascer-
1142 taining the operativeness of devices constructed in accordance with U. S. patent No. 217,838, dated July 22nd, 1879, granted George Westinghouse, Jr., now desires to make further response to that request as follows:

Defendants are ready and willing to exhibit the said experiments and tests on Thursday, April 12th, 1894, at 2 p. m. in the presence of counsel and two expert witnesses on behalf of complainants,

under such conditions as will be reasonable for both parties, with the object in view of guarding against possible misrepresentation thereafter as to what were the actual results shown by the said experiments and tests. And counsel for defendants proposes the following conditions, to wit:

First, that the defendants be represented at the tests by one counsel and two witnesses and complainants be represented by a like number.

Second, that while making the tests and experiments notes or written memoranda shall be kept of the tests and experiments as made and of the results of the same.

Third, that from said notes or memoranda the persons present as witnesses for defendants, shall prepare a written statement briefly describing and setting forth the tests and experiments and the results of each test, and that each witness present on behalf of defendants may be called the next morning, Friday, April 13, 1894, at 10.30 o'clock to testify and subscribe to this statement under oath, subject, of course, to the cross-examination of counsel for complainants.

Respectfully,

CHAS. B. MANN,
For Defendants.

Baltimore, Maryland, April 10th, 1894.

BALTIMORE, MD., April 13, 1894.

1143 Testimony on behalf of defendants, taken in accordance with the foregoing notice, at the office, No. 544 Equitable building.

Present: Charles B. Mann, Esq., of counsel for defendants; J. Snowden Bell, Esq., of counsel for complainants.

GEORGE A. BOYDEN, being recalled, deposes and says, in answer to interrogatories propounded to him by Charles B. Mann, Esq., of counsel for defendants, as follows, to wit:

349 Q. Are you the same George A. Boyden who has heretofore testified in this cause?

A. I am.

350 Q. Please give an account of the repetition of the experiments and tests with valve devices constructed according to patent 217,838, made yesterday at the shops of the Boyden Brake Company, which experiments and tests you and Mr. Gwinn have heretofore testified to; and also state the occurrences that took place on that occasion.

A. Yesterday at the shop of the Boyden Brake Company, I repeated the tests referred to in your question, in the presence of Messrs. J. Snowden Bell, H. H. Westinghouse and D. L. Barnes, representing the complainants, and Mr. Chas. B. Mann, L. Gwinn and myself, representing the defendants.

The tests made and the results were as follows:

Fifty automatic air brakes having the capacity of automatic air brakes as used in the year 1879, were mounted on the test-rack heretofore described, with relief valves constructed in accordance

with U. S. patent, No. 217,838, dated July 22, 1879, granted George Westinghouse, Jr.

First. The apparatus was charged with about 70 pounds of air pressure, all the auxiliary reservoirs charging up.

Second. The engineers' valve handle was placed in the "graduating position" and all the brakes were gradually applied, the degree of application being varied as desired.

1144 Third. The engineers' valve was then placed in position to release the brakes, and all the brakes released.

Fourth. The brakes were then again charged with about 70 pounds air pressure.

Fifth. The engineers' valve was then placed in position for "emergency" applications, and all the brakes quickly applied; the time required from the movement of the engineers' valve until the pressure equalized in the fiftieth brake-cylinder and auxiliary reservoir, was about ten and one-half seconds.

Sixth. The engineers' valve was then moved to release the brakes; all the brakes released but one. The occasional non-release of a brake in a train of 50 cars is not an unusual thing with the best brakes in use today. The failure of this one brake out of the fifty to release, was not attributable to the device of patent, No. 217,838. The apparatus was then recharged with about 70 pounds air pressure.

Seventh. The twenty-fifth hose coupling was then uncoupled to represent an automatic action of the brakes as occurs in the practical use of brakes when a train accidentally separates or breaks into two sections. In this test the twenty-five brakes on the rear end of the test-rack applied *quickly*. The twenty-five brakes on the forward end of the test-rack applied more slowly, which would be the preferable manner in practice, because the forward part of the train would move far enough ahead to prevent the rear part from colliding with it, as the rear section would be stopped in a shorter distance than the front section would be.

Eighth. We now removed all valves of patent, No. 217,838, and restored the caps of the hose coupling; the test-rack being now equipped with automatic brakes having the capacity of air brakes as in 1879, using "plain triple valves."

Ninth. The brakes were then recharged with air pressure.

Tenth. The engineers' valve was then again placed in position for an "emergency" application. This test was the same as 1145 in the fifth test, except that none of the relief valves of patent, No. 217,838, were used. In this test all the brakes applied, *but much slower* than they did in the said fifth test; the time now required from the movement of the engineers' valve until the pressure equalized in the fiftieth brake-cylinder and auxiliary reservoir was about 31 seconds, or twenty and a half seconds slower than when using the valve device of patent 217,838.

The foregoing comprised the tests made on the test-rack relative to the operativeness of the device of patent, No. 217,838, which Mr. Gwinn and I mentioned in our previous testimony.

The main points or substance of this account which I have now

given of these repeated tests, were gone over and stated aloud in the presence and hearing of all the persons in attendance while these tests were being made, including the three representatives of the complainants in this suit, and they and we all agreed that said main points of the tests were fairly and correctly stated.

After these tests had been made, the representatives of the complainants made inquiry of the representatives of the defendants asking in effect if we would make some further experiments, and suggesting that they wanted to put the engineers' valve in the "running position" to see how the brakes would release in that position. As this "running position" is one that is not used in practice to release the brakes, I declined to make this test; because first, the proposed test would be more severe than the standard brakes of today are subjected to in practice when releasing; and, second, the valve devices of patent 217,838, which I had constructed, were *not* made for the purpose of comparing *their* action with that of the standard brakes of 1894, *fifteen years after the invention of patent 217,838*. These valve devices were made simply to demonstrate if they would work as set forth in the specification thereof, which they do, and having demonstrated this, it would not be consistent to make the test solicited by complainants' counsel, as neither 1146 the valve device of patent No. 217,838, nor any other brake-valve, were intended to release under the conditions named in the solicited test.

The complainants' counsel also requested that we should have new pistons made which would tightly fit in the cylinders of the devices of patent 217,838. This was also declined, because, I know the devices are made in accordance with patent 217,838, for the simple reason that they work as the specification of that patent states they should work, and they produce the result which the devices of patent 217,838, of 1879, were invented to produce.

Cross-examination by J. SNOWDEN BELL, Esq., of counsel for complainants:

351 X Q. When you say that the 50 automatic air brakes used in the test of yesterday were provided with "relief valves constructed in accordance with U. S. patent No. 217,838, dated July 22, 1879, granted to George Westinghouse, Jr.," you refer, do you not, to the appliances made under your direction, and referred to in the testimony given last week by yourself and Mr. Gwynn, in which appliances the pistons were made one sixty-fourth of an inch less in diameter than the casing in which they worked?

A. I do.

352 X Q. When you say, referring to yesterday's proceedings, that "they (the three representatives of the complainants) and we all agreed that said main points of the tests were fairly and correctly stated," you refer, do you not, to the verbal statements made in the course of these demonstrations?

A. I refer to the conversation we had after the tests. Mr. H. H. Westinghouse suggested that before separating he thought it was

well for us to have an understanding between us all if we agreed on the results, of the tests; and this is what I referred to in my answer, pertaining to our mutual understanding.

353 X Q. You say that at yesterday's tests, the complainants' counsel requested that you would have new pistons made, etc.

1147 Are you not in error as to this statement, and is it not the fact that what complainants' counsel requested was that you would make a test with devices having their pistons fitting the cylinders without the slackness of a difference of one sixty-fourth of an inch in diameter between the pistons and the cylinders which exists in the devices with which the tests were made?

A. I did not make a note of the exact phraseology used by the complainants' counsel, but my understanding at the time was that he wished a test made with pistons fitting the cylinders more tightly than those that were used; as we did not have such pistons, I could only make such a test by first having new pistons made, which would have taken considerable time, and was one of the reasons why I declined.

Counsel for complainants calls the attention of counsel for defendants, that his request made at our last session, as yet remains unanswered, such request being that complainants' counsel should be furnished with the 50 valve devices of patent 217,838, with which Mr. Boyden's tests were made in order that the complainants' may make test thereof upon their own testing rack. This request was made partly for the purpose of enabling the complainants to verify the correctness of the tests heretofore made, and partly to enable the court to be more fully informed as to the question of the operativeness in practice of the devices, without involving the delay which will be caused if complainants are obliged to duplicate these devices for their own experiments. A reply on the record to this request is now asked for.

Counsel for defendants replies that defendants have fully exhibited the devices and repeated the tests which they previously made, in the presence of counsel for complainants and two expert witnesses, and having done this, counsel does not perceive that defendants are under any obligation to furnish complainants with their devices, and accordingly declines.

G. A. BOYDEN.

1148 LEVEN J. GWINN, being recalled, deposes and says, in answer to interrogatories propounded to him by Charles B. Mann, Esq., of counsel for defendants, as follows:

34 Q. Are you the same Leven J. Gwinn who has heretofore testified in this cause?

A. I am.

35 Q. Please state whether you were present yesterday at the shops of the Boyden Brake Company, while the experiments and tests were made, to which Mr. Boyden has testified this morning in answer to question 350, and if yea, state whether you have read the

statement made by Mr. Boyden, in answer to that question, and whether the same is true and correct.

A. I have read carefully the statement made by Mr. Boyden this morning in answer to question 350, in which he gives an account of the repetition of tests he made yesterday in the presence of the three representatives of the Westinghouse Air-brake Company. I was present during those tests, and assisted in making them. Mr. Boyden's statement is true, and an accurate account of what was done on that occasion.

Cross examination by J. SNOWDEN BELL, Esq., of counsel for complainants:

36 Q. Do you agree substantially with Mr. Boyden in the answers he gave this morning to my cross-questions?

A. I do agree with Mr. Boyden in regard to his answer to cross-question 351; as to the other two cross-questions, I wasn't present during the conversations referred to and therefore cannot say whether those two answers are correct or not.

LEVEN J. GWINN.

Adjourned *sine die*.

1149 & 1150 United States Circuit Court in the District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WEST-
INGHOUSE AIR BRAKE COMPANY
vs.

BOYDEN POWER BRAKE CO.; GEORGE A.
Boyden, President; Charles B. Mann, Secre-
tary, William Whitridge, Treasurer.

In Equity. No. 321.

I, George Morris Bond, a United States commissioner as afore-said, before whom the within depositions were taken, do hereby certify that on the 4th day of April, 1894, and on the various days adjourned therefrom, ending on the 13th day of April, 1894, the several sittings hereinafter noted were attended by counsel of the complainants and defendants in the above-entitled cause and by the witnesses, George A. Boyden, who was recalled, and Leven J. Gwinn, and that said Gwinn was by me duly sworn, and the testimony of both witnesses was then reduced to writing by my sworn clerk, and thereafter subscribed by the said witnesses.

And I do further certify that I am not of counsel or attorney for either of the parties to the said cause, and that I am not interested in the event of the said cause.

Given under my hand and seal at the city of Baltimore, within the district of Maryland, this thirteenth day of
[COM'R'S SEAL.] April, in the year of our Lord one thousand eight hundred and ninety-four.

GEORGE MORRIS BOND,
U. S. Commissioner for Maryland.

1151 DEFENDANTS' EXHIBIT "COPY OF WESTINGHOUSE FILE-WRAPPER AND CONTENTS" OF PATENT No. 360,070.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE.

To all persons to whom these presents shall come, Greeting :

This is to certify that the annexed is a true copy from the files of this office of the file-wrapper and contents in the matter of the letters patent granted George Westinghouse, Jr., March 29, 1887, number 360,070, for improvement in fluid-pressure automatic brake mechanism.

In testimony whereof I, C. E. Mitchell, Commissioner of Patents, have caused the seal of the Patent Office to be affixed this [SEAL.] 14th day of December, in the year of our Lord one thousand eight hundred and eighty-nine, and of the Independence of the United States the one hundred and fourteenth.

C. E. MITCHELL,
Commissioner.

1152 To the Commissioner of Patents :

Your petitioner, George Westinghouse, Jr., residing at Pittsburgh, in the county of Allegheny and State of Pennsylvania, a citizen of the United States, respectfully prays that letters patent of the United States may be granted to him for the improvements in fluid-pressure automatic brake mechanism set forth in the annexed specification; and he hereby appoints [George H. ^{J. Snowden} Bell,

Christy,]* of Pittsburgh, Pennsylvania, his attorney, with full power of substitution and revocation, to prosecute this application, to alter and amend the specification, to appeal or withdraw in case of rejection, to receive the patent when granted, and to transact all business in the Patent Office relative thereto.

GEORGE WESTINGHOUSE, JR.

[* Words enclosed in brackets erased in copy.]

1153

Specification.

To all whom it may concern :

Be it known, that I, George Westinghouse Jr. residing at Pittsburgh in the county of Allegheny and State of Pennsylvania, a citizen of the United States, have invented or discovered certain new and useful improvements in fluid-pressure automatic brake mechanism of which improvements the following is a specification :

1154 The object of my invention is to enable the application of brake-shoes to car wheels by fluid pressure to be effected with greater rapidity and effectiveness than heretofore, more particularly in trains of considerable length, as well as to economize compressed air in the operation of braking by utilizing in the brake-cylinders the greater portion of the volume of air which, in former practice, was directly discharged into the atmosphere. To this end, my invention, generally stated, consists in a novel combination of a brake-pipe, an auxiliary reservoir, a brake-cylinder, and a "triple-valve" device governing, primarily, communication between the auxiliary reservoir and the brake-cylinder, and secondarily, communication directly from the brake-pipe to the brake-cylinder. The improvements claimed are hereinafter fully set forth.

15 In the application of the Westinghouse automatic brake as heretofore and at present commonly in use, each car is provided with a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve, the triple valve having three connections, to wit : one to the main air-brake pipe, one to the auxiliary reservoir, and one to the brake-cylinder. The main air pipe has a stop-cock at or near each of its ends, to be opened or closed as required and is fitted with flexible connections and couplings for connecting the pipes from car to car of a train so as to form a continuous line for the transmission of compressed air from a main reservoir supplied by an air pump on the engine. When the brakes are off or released, but in readiness for action upon the wheels of the train, the air which fills the main reservoir and main air pipes has a pressure of from sixty-five to seventy-five pounds

2

1155 to the square inch, and, by reason of the connections referred to, the same pressure is exerted in the casings of the triple valves on both sides of their pistons and in the auxiliary reservoirs connected therewith. At the same time passages called release ports are open from the brake-cylinders, to the atmosphere. When it is desired to apply the brakes, air is allowed to escape from the main air pipes through the engineer's valve, thereby reducing the pressure in the main air pipes, whereupon the then higher pressure in the auxiliary

reservoirs moves the pistons of the triple valves, so as to first close the passages from the triple valves to the brake-pipe and at the same time close the release ports of all the brake-cylinders, and then open the passages from the auxiliary

^{to the brake-cylinders}

reservoirs, & the pistons of which are forced out by the

Insert com-

Jan. 19, '87. pressed air thereby admitted to the brake-cylinders, applying

the brakes by means of suitable levers and connections, all of which mechanism is fully shown in various letters patent granted to me.

The application of the brakes with their full force has heretofore required a discharge of air from the main pipe sufficient to reduce the pressure in said pipe below that remaining in the auxiliary reservoir after the brakes have been fully applied, and it has been found that while the brakes are sufficiently quick in action on comparatively short trains, their action on long trains of from thirty to fifty cars, which are common in freight service under present practice, is in a measure slow, particularly by reason of the fact that

^{required to be discharged from}

^{to set the brakes}

all the air & [in]* the main pipe & must travel from

Insert the rear of the

Feb. 5, '87. train to a single discharge opening on the engine. This dis-

3

1156 charge of air at the engine has not only involved a serious loss of time in braking, but also a waste of air. Under my present invention a quicker and more efficient action of the brakes is obtained, and air which has been heretofore wasted in the application of the brakes is almost wholly utilized to act upon the brake pistons.

In the accompanying drawings: Figure 1, is an inverted plan view of a railroad car illustrating the application of my invention; Fig. 2, a longitudinal section, on an enlarged scale, through the triple valve, at the line *x, x*, of Fig. 4; Fig. 3, a transverse section through the same at the line *y, y*, of Fig. 2; Fig. 4, a bottom plan view of the cap or drain-cup of the triple valve; Fig. 5, a longitudinal section through the triple valve, at the lines *z, z*, of Fig. 3, and *w, w*, of Fig. 6; Fig. 6, a partial bottom view of the triple valve, and; Fig. 7, a longitudinal central section through the brake-cylinder and auxiliary reservoir, with the triple valve in elevation.

In the practice of my invention, each railroad car 1, on which it is applied, is as heretofore provided with a main air pipe 2, governed by stop-cocks 3, adjacent to its ends, and

[* Word enclosed in brackets erased in copy.]

having a flexible connection 4, and coupling 5, at each end to admit of being coupled to the main pipe of the tender or the adjacent car or cars of a train. An auxiliary reservoir 6, and brake-cylinder 7, are secured in convenient position below the sills of the car, the brake-cylinder having a piston 52, by the movement of which, through a system of lever connections which do not form part of my present invention, the brake-shoes 9, are applied to and released from the wheels

4

1157 of the car, compressed air being supplied to and released from

the brake-cylinder 7, as the pressure in the main air pipe is reduced or reinstated respectively, by means of a triple valve 10, the casing or chest of which communicates with the main

5 air pipe, the auxiliary reservoir, and the brake-cylinder.

So far as the performance of its preliminary function in ordinary braking is concerned, that is to say, effecting the closure of communication between the main air pipe and the auxiliary reservoir, and the opening of communication between

10 the auxiliary reservoir and the brake-cylinder in applying the brakes, and the reverse operations in releasing the brakes, the triple valve 10, accords substantially with that set forth in letters patent of the United States No. 220,556, granted and issued to me October 14, 1879, and is not therefore, saving

15 as to the structural features by which it performs the further function of effecting the direct admission of air from the main air pipe to the brake-cylinder, as presently to be described, claimed as of my present invention. Certain of its elements devised and employed by me prior thereto, will however be herein specified in order to render its construction and operative relation to other members of the brake mechanism

20 fully intelligible.

Insert
Feb. 5, '87.

The case or chest in which the operative mechanism of the

25 triple valve 10, proper is mounted, is fixed ^{under or on} a [to]* the car body in any convenient position relatively to the auxiliary reservoir 6, and brake-cylinder 7, being, in this instance, shown as secured directly to one end of the auxiliary reservoir, in line axially therewith and with the brake-cylinder which is secured to its opposite end. The triple-valve case is fit-

5

1158 ed at one end with a cylindrical sleeve or bushing 11, which is bored out truly and forms the chamber of a piston 12, which is fixed upon a stem 13, carrying, as in my letters patent No.

[* Word enclosed in brackets erased in copy.]

220,556 before mentioned, a slide-valve 14, which controls communication between the auxiliary reservoir and the brake-cylinder and between the brake-cylinder and release port 15, respectively. The auxiliary reservoir 6, is continuously in communication with the chamber 11, on one side of the piston 12, through the longitudinal chamber 24, of the case in which the slide-valve 14, moves, and the triple-valve case communicates, by a passage 16, with the brake-cylinder, and, by a passage 17, with the main air pipe 2. The passage 17, leading from the main air pipe, communicates, by a passage 18, with the cap, or, as it is ordinarily termed, the drain-cup, 19, of the triple valve, from which passages 20, lead into the piston chamber 11. A four-way cock 21, controls the passages 16, 17, 18, and a passage 22, leading to a port 23, in the face or seat of the slide-valve 14. When in the position shown in the drawings, communication is continuously maintained between the main air pipe 2, and piston chamber 11, through the passages 17 and 18, drain-cup 19, and passages 20, and by turning the cock 21, so as to establish communication between the passages 16 and 17, the triple valve and auxiliary reservoir will be cut out from the main air pipe, and the mechanism can be operated as a non-automatic brake, the admission of air under pressure to the main air pipe and brake-cylinder effecting, in such case, the application of the brakes. The entire brake mechanism of the car, other than the main air pipe, may be put out of action, when for any reason required, by turning

6

1159 the cock 21, into position to cover the passages 16 and 18, the main air pipe then serving only for the transmission of air between the portions of the train line made up by the main air pipes of the remaining vehicles.

The slide-valve 14, is loosely connected with the stem 13, of the piston 12, and, by a pin 25, extending across the stem and fixed in the side plates of the valve, is prevented from being separated from the stem when removed for examination; it is held up to its seat in the chamber 24, by a spring 26. The valve partakes in the reciprocating movements of the stem 13, being moved in one or the other direction by a collar 27, and a shoulder 28, respectively, on the stem. Said collar and shoulder are located at a distance apart slightly greater than the length of the valve 14, so that a limited degree of traverse of the stem 13, and piston 12, in each direction is effected without imparting movement to the valve. A graduating valve 29, secured upon a stem 30, which is moved by the piston stem 13, governs a passage 31, in the slide-valve 14, said passage communicating, by a lateral port 32, with the valve chamber 24, and, consequently, with the auxiliary reservoir. A cavity or passage 33, is formed on the face of the slide-valve 14, of such length as to establish

communication during a portion of the traverse of the valve between the port 23, of the valve chamber 24, which is open
 25 to the passage 16, leading to the brake-cylinder, and a port 34, communicating with the relief port 15. The construction and relative arrangement of the piston stem 13, slide-valve 14, and graduating valve 29, are substantially similar to those of the corresponding parts as heretofore employed by me

7

1160 and exemplified in my letters patent No. 220,556, but, under my present invention, these are supplemented by a port 35, leading from the end of the valve adjacent to the opening of the chamber 24, which communicates with the auxiliary reser-
 5 voir, to the face of the valve, so as, at the limit of traverse of the piston stem in the application of the brakes, to establish communication, directly through said passage, between the auxiliary reservoir and the port 23, and passages 22 and 16, leading to the brake-cylinder.

10 The piston stem 13, abuts, when the stem 13, and piston ^{for} Nov. 27, '86. 12, are moved [from]* the major portion of their traverse towards

the drain-cup 19, against a stem 36, which is fitted to slide freely in line axially with the stem 13, in an open-ended
 15 bushing 37, in the end of the drain-cup 19, adjoining the piston chamber 11, and in guide formed in a screw-cap 38, closing the opposite end of the drain-cup. A spring 39, surrounding the stem 36, and bearing against the inside of the cap 38, and against a collar 40, on the stem 36, maintains the
 20 latter in the position shown in Fig. 2, except when a sufficient pressure of air is admitted from the auxiliary reservoir to the piston chamber to overcome the resistance of the spring and effect movement of the piston 12, beyond the point at which its stem 13, comes in contact with the stem 36.

25 So far as hereinbefore described, the triple valve accords in all substantial particulars with and is adapted to operate similarly to those of my letters patent Nos. 168,359, 172,064, and 220,556, and, in order that it may perform the further functions requisite in the practice of my present invention, it is provided with certain additional members which

8

1161 will now be described. For the purpose of effecting the admission of air directly from the main air pipe 2, to the brake-cylinder 7, when it is desired to apply the brakes with great
 5 rapidity and full force, an auxiliary slide-valve 41, is connected to and moves with the stem 36, said valve working over

[* Word enclosed in brackets erased in copy.]

a face in the bushing 37, between the piston chamber 11, and drain-cup 19, and governing a port 42, in said face, leading into a chamber 43, adjoining the same. The valve 41, has lateral wings or plates, fitting on each side of the stem 36, between shoulders or collars thereon, and is held thereto, when the stem is removed between collars or shoulders thereon abutting against its ends, by a pin 44, in its wings, a spring 45, acting to hold it to its seat in the bushing 37, when in position. The chamber 43, communicates, by a passage 46, (Fig. 5) with a chamber 47, in the end of the case of the triple valve adjacent to the auxiliary reservoir, from which chamber a passage 48, leads through the auxiliary reservoir into the brake-cylinder 7. The chamber 43, is further provided with a check-valve 49, which opens outwardly into and controls the passage of air into the passage 46, said valve being held to its seat by a light spring 50, and serving to prevent the return of air from the brake-cylinder when the pressure in the main air pipe is reduced below that in the brake-cylinder, as in the case of the separation of the cars of the train by the breaking of a coupling.

In the operation of the brake mechanism as above described, air from the main reservoir and main air pipe passes through the passages 17, 18, drain-cup 19, and passages 20, into the piston chamber 11, forcing the piston 12, to the left-

9

1162 hand extremity of its stroke and uncovering a small feeding groove 51, in the piston chamber, through which air passes into the auxiliary reservoir 6, until the pressure in the latter is equal to that in the main air pipe, the brake-cylinder being meanwhile in communication with the atmosphere through the passages 16 and 22, valve cavity 33, and ports 23, 34, and release port 15. To apply the brakes in making ordinary stops, a portion of the air is discharged from the main air pipe by the engineers' valve, thereby correspondingly reducing the pressure in the main air pipe, whereupon the higher pressure in the auxiliary reservoir moves the piston 12, to the right, covering the feeding groove 51, and thus preventing the return of air from the auxiliary reservoir to the main air pipe, the movement of the piston continuing until arrested by the decrease of pressure in the auxiliary reservoir, or by the stem 36, and its spring 39. The movement of the slide-valve 14, then closes the port 23, preventing escape of air from the brake-cylinder, and places the passage 31, partly or wholly in communication with the port 33. The small auxiliary valve 29, having been meanwhile unseated, by the movement of the piston stem, compressed air from the auxiliary reservoir passes through the lateral port 32, and passage 31, of the slide-valve 14, and the passages 22, and 16, of the triple-valve case to the brake-cylinder, forcing out the piston, and,

- 25 through an appropriate system of levers and connections, applying the brakes. When the pressure in the auxiliary reservoir has in this operation, been reduced by expansion into the brake-cylinder until it is slightly below the pressure in the main air pipe, the pressure on the air-pipe side of the piston

10

- 1163 12, forces the piston 12, in the opposite direction until the auxiliary valve 29, closes the passage 31, thereby arresting the further flow of air from the reservoir to the brake-cylinder and holding the brakes with a force proportionate to the
 5 reduction of pressure in the brake-pipe. To release the brakes, the pressure in the main air pipe is increased by admitting air from the main reservoir, whereupon the resultant increase of pressure in the piston chamber 11, forces the piston 12, back to its original or normal position, permitting
 10 the escape of air from the brake-cylinder 7, the piston 52, of which is returned to its position by a spring 53, releasing, in its backward movement, the brake-shoes 9, from the wheels, and at the same time the auxiliary reservoir is recharged. The admission of air to the brake-cylinder through
 15 the passage 31, which is opened just before the piston stem comes in contact with the graduating stem, and which corresponds to the feed-passage heretofore employed, suffices for the ordinary requirements of braking in regular service.

- In the event however of its becoming necessary to apply
 20 the brakes with great rapidity and with their greatest available force, the engineer, by means of the valve at his command instantly discharges sufficient air from the front end of the main air pipe, to effect a sudden reduction of pressure of about twenty pounds per square inch therein, whereupon the
 25 piston 12, of the triple valve is forced to the extreme limit of its stroke in the direction of the drain-cup 19, carrying with it the stem 36, and auxiliary slide-valve 41, which instantly uncovers the port 42, and discharges air from the main air pipe through the opening of the check-valve 49, and the

11

- 1164 passages 46 and 48, to the brake-cylinder, and each car being provided with one of these devices, it will be seen that they are successively moved with great rapidity, there being practically, on a train of fifty cars, fifty openings for dis-
 5 charging compressed air from the main pipe instead of the single opening heretofore commonly used. Not only is there a passage of considerable size opened from the brake-pipe on each car, whereby the pressure is more quickly reduced, but the air so discharged is utilized in the performance of pre-
 10 liminary work, it being found in practice that the air so taken from the pipe will exert a pressure of about twenty-five

pounds in the brake-cylinders. When the piston 12, arrives at the extremity of its stroke, as above specified, the supplemental port 35, of the slide-valve 14, is brought into communication with the port 33, and passages 22 and 16, which serves to discharge the reservoir pressure into the brake-cylinder, thereby augmenting the pressure already exerted in the brake-cylinder by the air admitted from the main air pipe. Upon the reduction of the pressure in the main air pipe below that in the brake-cylinders, as by the breaking in two of the train, the check-valve 49, closes communication between the passages 46 and 18, thereby preventing the return of the air from the brake-cylinder to the main air pipe. The feed-opening for the admission of air from the auxiliary reservoir to the brake-cylinder is purposely made of comparatively small diameter, it having been determined by experiment that the initial application of the brakes should not be made with maximum force, and this opening may be made of such size as to apply the brakes exactly in accord with the requirements of the

12

1165 most efficient work.

In using the terms "triple valve" and "triple-valve device," I refer to a valve device, however specifically constructed, having a connection with the main air or brake pipe, another with an auxiliary reservoir or chamber for the storage of power, and another with a brake-cylinder or its equivalent for the utilization of the stored power and with a release or discharge passage for releasing the operative power from the brake-cylinder, whether the valves governing these passages or connections are arranged in one or more cases and are moved by a piston or its equivalent or by a series of pistons or their equivalents, there being numerous examples in the art of constructions varying materially in appearance whereby these functions are performed, both in plenum and vacuum brake mechanisms.

While I have herein described my invention as applied in a brake mechanism utilizing air under pressure, such as is in general and approved use, I do not desire to limit myself to brakes so operated, as my improvements are likewise susceptible of application, without variation of principle, in connection with brakes worked by atmospheric pressure.

Substitute B.
Jan. 20, '87.

25

Further, while in the specific construction described and shown, the function of admitting air from the main pipe is performed by a valve separate from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve integral with the main valve and formed by an extension thereof, would be included in and embody the essential operative features of my invention.

13

1166 I claim as my invention and desire to secure by letters patent:

Substitute A.
Jan. 19, '87.

5

1. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve provided with a device for admitting air directly from the main air pipe to the brake-cylinder, substantially as set forth.

2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder and which by a further traverse, admits air directly from the main air pipe to the brake-cylinder, substantially as set forth.

3. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder and which, by a further traverse, admits air directly from the main air pipe to the brake-cylinder and effects a second admission of air from the auxiliary reservoir to the brake-cylinder, substantially as set forth.

[Matter enclosed between rules erased in copy.]

4. The combination, in triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber

14

1167 therein, a valve moving with the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake cylinder and to the atmosphere respectively, and an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake-cylinder respectively, substantially as set forth. 5

5. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere respectively, an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake-cylinder respectively, and a check or non-return valve interposed between the auxiliary valve and the passage leading therefrom to the brake-cylinder, substantially as set forth. 10 15

6. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere respectively, an auxiliary stem mounted in the cap of the case in position to be moved longitudinally by the piston stem in the latter portion of its traverse in the direction required 20 25

15

1168 for the application of the brakes, a spring bearing against a collar on the auxiliary stem and against a fixed abutment, and an auxiliary valve connected to the auxiliary stem and controlling communication between passages leading to connections with a main air pipe and with the brake-cylinder respectively, substantially as set forth. 5

7. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, an auxiliary valve actuated by the piston-stem and controlling communication between passages leading to connections with a main air pipe and with a brake-cylinder respectively, and a main valve connected to the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere respectively, said main valve having a supplemental port or passage which establishes communication between 10 15

the auxiliary reservoir and brake-cylinder connections at or near the limit of the traverse of the main valve in effecting

1169 the application of the brake under maximum pressure, substantially

as set forth.

In testimony whereof, I have hereunto set my hand.

 19, 1886. Se. No., 219,353.

WASHINGTON, D. C., Jan. 19th, 1887.

Hon. Commissioner of Patents.

SIR: Acknowledging the official letter of 14th inst.
 I hereby amend the specification as follows, to wit:

1/ In line 14, page 3, after "reservoirs," insert: "to
the brake cylinders."

Cancel the comma after "air," line 15, page 3.

1/ Cancel claim 1, and substitute:

"1. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, a triple valve, and an auxiliary valve device, actuated by the piston of

- A. the triple valve, and independent of the main valve therefor admitting air, in the application of the brake, directly from the main air pipe to the brake-cylinder, substantially as set forth

It is respectfully submitted that while the Boyden patent No. 280,285 referred to, shows what the inventor terms "an always-open one-way passage" by which communication may be estab-

- lished under certain conditions between the main air pipe and train-pipe, and hence might be held to meet the terms of the claim as originally broadly drawn, yet it fails to embody a device which in structure or function corresponds with the auxiliary valve of applicant, which in no sense relates to "an always-open one-way passage."

The amended claim above submitted prescribes a valve device actuated by the piston of the triple valve for admitting air to the brake-cylinder in the application of the brake, while Boyden's check-valve *d*, is not actuated by the piston, and is designed to recharge the auxiliary reservoir and brake-cylinder while the brakes are on.

It is submitted as to claim 2, that a piston which by its preliminary traverse admits air from the auxiliary reservoir to the brake cylinder and by its further traverse admits air directly from the main air pipe to the brake-cylinder, as set forth in said claim, is not found in the Boyden patent, the check-valve *d*, of which is described as actuated by the manipulation of the cock *g*, on the locomotive "to recharge and continue charging the reservoir and brake-cylinder while the brakes are applied." (Boyden patent, lines 56-69, page 2.)

Further, it will be observed that the space between the lower end of Boyden's piston *G* and the port in the left-hand side thereof governing the passage *D*, is equal to the width of the face of the upper end of the slide-valve *H*, so that the admission will be coincident through the passages *C'* and *D*, thus evidencing that both ^{are} *A* opened by the preliminary traverse of the piston.

It is to be understood that applicant does not seek to broadly claim a device for admitting air directly from the main air pipe to the brake-cylinder, as the four-way cock long heretofore employed by him (similar to the cock *K* of the Boyden patent)

would be a structure of such character. When however the triple valve is provided with an auxiliary valve operated by its piston which performs a new function additional to that of the triple valve as previously employed, it is believed that such combination is wholly novel.

With reference to the Boyden invention as shown in figure 2, it will be noticed that the upper piston 1, is intended to be acted upon by the pressure in the chamber above it in applying the brakes, and that the pressure in this chamber is supposed

to be maintained at a constant point after the air within it has expanded. Practice has shown that it is utterly impossible to pack a piston or device such as illustrated so that the valve constructed as shown would be an impracticable device. Boyden had no idea of quickly applying his brakes, and has provided no means whereby the brakes can be applied with a moderate amount of force, as is fully provided for by applicant and Boyden's construction involves the full application of the brakes in all cases, which would render the device inoperative for the obvious requirements of railway service.

He seems to have conceived the idea of charging the brake-cylinder and reservoir when the brakes are on, assuming that the pressure in the brake-cylinder and reservoir might leak away, and might, therefore, need replenishing.

The check-valve *d*, is provided with a spring tending to hold it to its seat. If this spring were made with considerable tension, the piston and slide-valve would be forced up to the position shown in the drawing without the possibility of applying more pressure to the brake-piston. If, on the contrary, the valve

1176 *d* is made so that the resistance to the passage of air is less than,

the resistance of the piston, the reservoir and brake-cylinder will be charged and the release of the brakes will be prevented unless the chamber *L* is made of nearly the same proportion as the auxiliary reservoir.

In the Boyden invention, to apply the brakes with full force requires the discharge of the greater portion of the air from the brake-pipe, after which he proposes to further increase the pressure in the brake-cylinder by allowing air to pass the valve *d*. If he were to attempt to apply the brakes with a moderate amount of force, the piston and slide-valve would descend admitting some air to the brake-cylinder, and would be released unless the piston *I* were to be made air-tight.

The recharging of the auxiliary reservoir where the ordinary Westinghouse triple valve is used, requires only a small passage through or by the piston. The feed-groove, which is shown in the cylinder, could be extended to a point reaching below the piston when the triple valve is in its middle position, that is, in the position to prevent air from passing either from the reservoir to the brake-cylinder, or from the brake-cylinder to the atmosphere. This feed-groove would allow the air to pass around the piston and recharge the reservoir. Experiments of this kind have been repeatedly made, but the difficulties arising from the inability to release the brake prevent the use of such a construction.

A model is filed herewith as suggested by the office.

Reconsideration upon the above points and amendment is requested.

Respectfully,

J. SNOWDEN BELL,
Att'y for Applicant.

DEPARTMENT OF THE INTERIOR,

U. S. PATENT OFFICE,

WASHINGTON, D. C., Jan. 22, 1887.

George Westinghouse, Jr., c. o. J. S. Bell, Pittsburg, Pa.

SIR: Your application for a patent for an improvement in fluid-pressure automatic brake mechanism, filed Nov. 19th, 1886, has been examined and allowed.

The final fee, twenty dollars, must be paid, and the letters patent bear date as of a day not later than six months from the time of this present notice of allowance.

If the final fee is not paid within that period the patent will be withheld, and your only relief will be by a renewal of the application, with additional fees, under the provisions of section 4897, Revised Statutes. The office aims to deliver patents upon the day of their date, and on which their term begins to run; but to do this properly applicants will be expected to pay their final fee at least twenty days prior to the conclusion of the six months allowed them

by law. The printing, photolithographing, and engrossing of the several patent parts, preparatory to final signing and sealing, will consume the intervening time, and such work will not be done until after payment of the necessary fees.

When you send the final fee you will also send, distinctly and plainly written, the name of the inventor and title of invention as above given, date of allowance (which is the date of this circular), date of filing, and, if assigned, the names of the assignees.

If you desire to have the patent issue to assignees, an assignment containing a request to that effect, together with the fee for recording the same, must be filed in this office on or before the date of payment of final fee.

Additional copies of specifications and drawings will be charged for at the following rates: Single copies, uncertified, 25 cents; twenty copies or more, 10 cents each. The money should accompany the order.

Very respectfully,

M. V. MONTGOMERY,

C. E. MITCHELL,

Commissioner of Patents.

[Printed on the margin:] The within title is that given by the examiner in charge as most appropriate to your invention. Should you desire a change in the same, satisfactory reasons must be given therefor on or before the payment of the final fee.

[Printed across the face:]  In remitting the final fee give the serial number at the head of this notice.

mechanism.

J. F. F.
M. H.

1186 (Here follows diagram marked pp. 1187 & 1188.)

FOLDOUTS TOO LARGE TO
BE FILMED

1189-1191 *Extracts from "Defendants' Exhibit Westinghouse 1886 Instruction Book."*

From page 3.

Our attention has been repeatedly directed to the importance of furnishing a complete and concise description of our brake apparatus, to be placed in the hands of those who are engaged in its operation or its maintenance. In the present book we have illustrated the general construction of the brake and all the more essential parts.

From page 7.

Too much importance cannot be attached to that portion of the instructions stating that engineers should use care and moderation in applying the brakes for ordinary stops. By applying them at a fair distance from the station, with moderate force, the train is stopped gently and without inconvenience to the passengers, while if they are thrown on with the utmost force possible, the train is jerked in a manner that is extremely disagreeable to the passengers.

Extract from "Defendants' Exhibit Westinghouse 1890 Instruction Book."

From page 19.

The plain automatic triple valve.

A perspective view of the plain automatic triple valve and locomotive-tender brake apparatus, is shown in plate 1, Fig. 3, and cross-sections of the triple valve in Figs. 4 and 4a, which will clearly show its construction. It is desirable that this triple valve be perpetuated for use with locomotive driving-wheel and tender brakes, to give a slightly slower action to the brakes thereon in cases of emergency action of the quick-action apparatus on cars.

The construction and operation of the plain automatic triple valve is substantially the same as that of the quick-action form, the quick-action valves being omitted, and pressure used only from the auxiliary reservoir in applying the brakes, and will not, therefore, require specific description.

1193

UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Schenectady, New York.

Improvement in Steam-power Brake Devices.

Specification forming part of Letters Patent No. 88929, dated April 13, 1869.

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Schenectady, in the county of Schenectady and State of New York, have invented a new and useful improvement in power car-brakes ; and I do hereby declare the following to be a full, clear, and exact description thereof, reference being had to the accompanying drawing, making a part of this specification, in which—

(Here follows diagram marked p. 1192.)

Figure 1 shows by a side elevation, partly in section, my improvement as mounted on and applied to an ordinary platform railroad-car. Fig. 2 is a sectional plan view as formed by a horizontal plane passing through the brake-cylinder, just below the body of the car. Fig. 3 is a vertical, and Fig. 4 is a cross section of the three-way cock by which I admit or cut off the supply of air to the brake. Fig. 5 is an outside view, and Fig. 6 is a longitudinal section of my improved coupling for uniting the brake-pipes of contiguous cars.

Like letters represent like parts of each.

My invention relates to the construction of a power car-brake for railway-cars or other like vehicles, to be operated by compressed air or other elastic compressible fluid ; and the nature of it consists, first, in the use of an auxiliary engine for compressing the air in a reservoir, from which it is to be conducted by suitable pipes and applied to operating the brakes, and also for pumping feed-water into the boiler, either or both ; second, in the construction of a reservoir for storing up the power to be derived from air or other elastic fluid under compression, such reservoir having a pipe or pipes leading to one or more brake-cylinders on or attached to each car, with a valve or cock in each pipe for turning on or off the supply of air ; third, in the construction and combination of devices by which the power thus communicated to the piston of the brake-cylinder may be from it applied to operating an ordinary hand-brake, or any other known form of simple or compound brake ; fourth, in the construction of an improved coupling for uniting the brake-pipe of contiguous cars, so made that when coupled they shall be always open for the passage of air to the brake-cylinders, but if uncoupled, when the brakes are down, the pressure of the air in the pipes will instantly close them.

To enable those skilled in the art to make and use my invention, I will proceed to describe its construction and manner of use.

 Thos. B. New
 R. C. Marshall

Inventor
 George Westinghouse, Jr.
 by Bakewell & Christy
 his Attys.

a represents a platform-car on which is mounted an auxiliary engine, *a' a''*, a feed-water-pumping cylinder, *c*, and an air-pump, *o*, and an air-reservoir, *d*. A single piston-rod connection, *e e'*, may answer for both pumps; or one piston-rod may lead from the auxiliary engine *a' a''* to the feed-water pump *c*, and another to the air-pump *o*. In either case the operation would be the same. *b* is a steam-pipe leading from the locomotive-boiler to the auxiliary engine *a' a''*. A water-pipe extends from the water-tank on the tender to the pumping-cylinder *c*, and by a piston working therein, water is fed through the pipe *c'* to the boiler. The air-pump *o* has the usual valves, and works on the principle of the ordinary air-pump, and compresses the air into the reservoir *d*. Each of these cylinders is fitted with the valves and cocks necessary to their successful operation.

From the reservoir *d* an air-pipe, *i*, leads down and back along under the cars of the train, the communication through the pipe being opened and closed by a three-way cock, *h*, presently to be described.

At any convenient point on or under each car a brake-cylinder, *m*, is attached, having a piston working closely therein. A pipe, *i'*, leads from the main pipe *i* to each brake-cylinder *m*, opening into it back of the piston *r*. The piston-stem *m'* plays through the opposite end of the brake-cylinder *m*, and at its outer end may be bifurcated, so as to operate against the brake-lever *n'*; or an adjustable bifurcated head, *n*, may be set thereon by a set-screw *n''*. The brake-lever *n'* and the brakes connected therewith may be simple or compound, or of any known or desirable construction. As shown, they are of the ordinary style. It will be observed that, with the construction and arrangement shown, the operation of the "doctor" or feed-water pump, and of the brakes, is in no way dependent on the movements of the locomotive. If steam be up, water can be fed into the boiler, even when the locomotive is standing, which end

is a desirable one, since it is sometimes far from convenient
1194 to run a locomotive and train forward or back merely to

replenish the supply of water in the boiler, and still more so at other times to slack up a train for the same purpose. In like manner, the operation of the auxiliary engine *a' a''* may be so regulated, even with the locomotive running at its highest speed, and with an occasional or even frequent application of the brakes, that a uniformly constant pressure of air can be preserved in the reservoir *d*. This auxiliary engine *a' a''*, with the pumps *c o* and reservoir *d*, may, and probably should be for convenience, mounted on or attached in some way to the locomotive or tender. As they are small, light, and not costly, they can be easily and cheaply applied. If it be desired to operate either alone, the connecting-valves of the other may be closed, and its piston work *in vacuo*, without in the least interfering with the working of the other.

The reservoir *d* being filled with compressed air, whenever it is desirable to apply the brakes the cock *h* is turned, and the air rushes along, through the pipes *i i'*, into the brake-cylinder *m*, forces its rod *m'* against the brake-lever *n'*, whereby the brakes *s* are instan-

taneously applied to the wheels s' , and the speed of the train at once checked. Of course, the more the air is compressed in the reservoir d , the more powerful will be its action on the brakes.

The cock h is a three-way cock—that is, it opens on three sides. When turned as in Fig. 4, the air flows freely through from the reservoir d , as described. On being turned one-quarter way around the orifice z comes into the tubular opening of the pipe i , leading to the brakes, and the orifice z' coincides with the orifice in the side of the valve-seat, so that communication is cut off from the reservoir d to the brakes, but opened from the brake-cylinders to the external atmosphere. The excess of air then escapes. The spiral spring x , Fig. 2, carries the piston r of the brake-cylinder m back to the head of the brake-cylinder, and the brakes are off. The length of throw to be given to the brake-lever n' may sometimes vary somewhat, and hence I use the adjustable head n . The bifurcation y , whether made in the head n or in the stem m' , is of such depth that if it be sometimes preferred to operate the brakes by hand, the levers n' will not be drawn out of the fork or slot of the bifurcated end; and to illustrate such use I have shown the ordinary hand-brakes l attached.

To provide for longitudinal motion of the cars independent of each other in starting or stopping, I use between each two cars a section of air-tight flexible pipe, k , made of india-rubber, or india-rubber and cloth, or other like flexible and air-tight material.

An important feature of my invention consists of the construction and combination of coupling-valves, which I use in the ends f of the pipe k , where they are jointed between cars. These valves are more perfectly illustrated in Fig. 6, where $f f$ represent the adjacent or coupling ends of the pipes k of two consecutive cars. The end f couple one into the other, and hooks g pass over the beveled shoulders u in the face of the coupling f , and prevent their coming uncoupled, except in case the car-coupling should break, or a car jump from the track, and then the hooks g would be disengaged and the coupling be uncoupled from each other. Inside each coupling f is a puppet-valve, p , having a stem, p' , playing through a guide or diaphragm, q , the two stems being of such length that when the couplings f are coupled together the stems will come together end to end, and each force back the other, so as to throw its valve p free from its seat, and make an uninterrupted communication through the pipe i from the reservoir d to the last valve of the last car. The rear stems p'' play through guides or diaphragms q' , and keep the valves p more carefully centered, so that the forward stem p' will always engage each other when the cars are coupled. The guides $q q'$ should be open, or have openings, to admit of the passage from one pipe to the next of the compressed air. Then, when the pipes are uncoupled by the breaking of the car-coupling, or by a car leaving the track, the compressed air having been applied to the brakes, its pressure will cause the valves p to come against their seat on the guides q , thereby closing the ends of the pipe and keeping the brakes on or down. Thus the danger from accident will be materially decreased. The stems p'' are made with shoulders y'

which rest against the guides $q' p'$ when the ends f are coupled and the valves p are opened. Consequently the valves p cannot set back against the guides q' to close them, nor can the compressed air, when admitted, close the valves p or either of them. When the pipes are coupled, the valves p must always be open. If they come uncoupled when filled with compressed air, they will be instantly closed, and must necessarily remain so. Hence, in the worst of disasters, the brakes will remain down if once applied.

Instead of the puppet-valves p , other forms of valves may be used, provided they be so arranged as to operate or open each other when the pipes f are coupled together. For this purpose flap-valves with stems may be used; also, instead of the diaphragms for guiding the stems, wings on the stems may be substituted. In that case the wings may be so made as to slide in the cylindrical or other shaped cavity of the couplings f .

The hooks g operate with sufficient rigidity to catch tightly in the grooves u , and hold the couplings f together against any ordinary force exerted longitudinally to which they would be subject; but by beveling slightly the holding shoulder of the grooves u , as shown, the hooks g would be disengaged, as in case of an accident, by any force sufficient to throw the car from the track or by the breaking of the car-coupling. In lieu of this device, however, other devices performing the same function may be substituted—that is, other means may be used to accomplish the same end, provided they be such as will hold the couplings f together against the operation of any force to which in use they are ordinarily subject, but not such as to prevent their being automatically uncoupled in case of accident. At the same time all such devices should be so made that the couplings may be readily uncoupled by hand.

The particular advantages connected with the apparatus described, in addition to those above referred to, are, that the brakes are under the control of the engineer, and can be instantaneously applied at any time, and with any degree of power within the strength of the machinery employed, and the brakes can be as instantaneously loosened. They are simple in construction, cheaply made, and can be applied to and used in connection with or used without the ordinary hand-brakes. By the use of the auxiliary engine the operation of the brakes is made independent of the operation of the locomotive, so that much or little power can be stored up in the reservoir d at any time, whether the locomotive be running fast or slow, or not at all; and, if desired, all the force of the air-pump can be applied to the brakes over and above the force that can be stored up in the reservoir. By this mode of operating brakes in connection with the couplings described, in case of accident the brakes may be instantaneously applied, and kept "on" till the whole train, or each separate car, if the car-couplings break, be brought to a complete stand.

What I claim as my invention, and desire to secure by letters patent, is—

1. The auxiliary engine, with connections to, and in combination

with, the air-pump, air-reservoir, and brake-cylinder, substantially as hereinbefore set forth.

2. The auxiliary engine arranged to operate in connection with a railroad-locomotive, feed and water pumps, substantially in the manner hereinbefore set forth.

3. The reservoir *d*, with pipes *i*, leading to one or more brake-cylinders on, or attached to, each car, with a valve or cock in each pipe for turning on or off the supply of air, arranged substantially as above set forth.

4. The brake-cylinder *m*, in combination with the pipe *i'*, and piston-stem connecting with the brake-lever, substantially as hereinbefore set forth.

5. The adjustable head *n* on the piston-stem *m'*, in connection with the brake-lever *n'*, substantially as hereinbefore set forth.

6. The valves *p*, arranged in the adjacent ends of the couplings *f*, and so guided by stems and guides or diaphragms as to operate to open each other when the couplings *f* are united, and automatically to close when forcibly uncoupled, substantially as above set forth.

In testimony whereof I, the said George Westinghouse, Jr., have hereunto set my hand.

1199 UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Improvement in Steam-power Air-brakes and Signals.

Specification forming part of Letters Patent No. 124,404, dated March 5, 1872.

Specification.

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Pittsburg, in the county of Allegheny and State of Pennsylvania, have invented a new and useful improvement in steam-power air-brakes and signal: and I do hereby declare the following to be a full, clear, and exact description thereof, reference being had to the accompanying drawing making a part of this specification, in which—

(Here follows diagram marked p. 1198.)

Figure 1 is an inverted view of a car-body with my improved apparatus attached thereto. Fig. 2 shows the arrangement of the air-brake pipes with reference to the main reservoir. Fig. 3, in connection with Fig. 2, illustrates the use of the apparatus for signaling. Fig. 4 is an enlarged view of the gauge-index, and Figs. 5 and 6 are enlarged and detached views of the tripping apparatus of Fig. 1.

Like letters of reference indicate like parts in each.

In the steam-power air-brake apparatus heretofore in use a single line of pipe conveys the compressed air from the main reservoir on the locomotive to each brake-cylinder. If this pipe becomes accidentally broken at any point it is, of course, useless for braking purposes from that point to the rear end of the train. For this and other reasons I have devised an apparatus consisting in part of a double line of brake-pipes, which may be co-operative or independently operative in braking at the pleasure of the engineer, and which as a separate device I have included in a separate application.

The improvement herein described relates to the same class of apparatus; and consists in the features of construction and combination, substantially as hereinafter claimed, by which, first, an air-reservoir, auxiliary to or independent of the main reservoir, is combined on each car with the brake-cylinder; second, by means of a cock or cocks, with suitable ports, such additional reservoir, when used as an auxiliary reservoir, is charged with compressed air from one brake-pipe, and the brake-cylinder from the other, such pipes in such use being interchangeable or not, at pleasure; third, and by means of a single cock with suitable ports either brake-pipe may be used for charging the reservoir and the other for operating

the brakes; fourth, when a car becomes disconnected from the train by accident or otherwise, a port or ports will thereby be opened in a communicating pipe or pipes, by which the air from such auxiliary reservoir will be admitted freely to the brake-cylinder, so as automatically to apply the brakes; and fifth, the conductor and engineer may communicate signals or orders to each other by the use of the brake-pipes and the compressed air.

Some of the functions above specified are performed by the apparatus described in the separate application above mentioned; and hence in such cases I limit myself in this application to the means set forth or their substantial equivalents.

To enable others skilled in the art to make and use my improvement, I will proceed to describe its construction and mode of operation.

The brake-pipes $B\ B^1$ extend along under the body of each car A from end to end, and the pipes of one car are coupled to those of the next by the hose and coupling connections described in patent granted to me August 8, 1870, and thereby connection is made with the main reservoir A^1 . The brake-cylinder C is of the usual construction. An air-receiver, D, is attached to the bottom of the car A. This receiver should ordinarily be somewhat larger than the brake-cylinder C, and strong enough to sustain a pressure of, say, one hundred pounds per square inch, more or less. It may be used as a reservoir auxiliary to the main reservoir A^1 , or as an independent reservoir, one on each car, for storing up the air necessary to apply the brakes. In this latter use I combine with it any known device for compressing air, such as an air-pump, fan-blower, steam-injector, &c.; and if an air-pump it may be worked by an eccentric on one of the car axles A^2 or in other known way. A pipe or air passage then extends directly or indirectly from it to the brake-cylinder C, with a stop-cock device therein, by which the compressed air is admitted at pleasure from such reservoir D to the brake-cylinder, so as to apply the brakes in the usual way. By the means

set forth reservoir D is recharged from time to time, as may be necessary, in order to keep a store or supply of compressed air always on hand and ready for use. But the chief use which I contemplate for this reservoir D is as an auxiliary to the main reservoir A^1 . One brake-pipe, B, I use in the ordinary way for conveying compressed air from the main reservoir A^1 to the brake-cylinder C, and the other pipe, B^1 , I always keep in open communication with the main reservoir A^1 , so that it is always filled with compressed air; but it is immaterial in the construction shown which pipe is used for either purpose. A cross-pipe, $B^2\ B^3$, connects the pipes $B\ B^1$, and from their point of junction the pipes $b\ b^1$ branch off, one to the brake-cylinder C and the other to the auxiliary reservoir D. At the junction of these pipes in a suitable case, d , I arrange a cock, d^1 , having two non-communicating ports, $a\ a^1$, such that in one adjustment they will open communication from B^2 to b , and from B^3 to b^1 ; and in the other adjustment from B^3 to b and from B^2 to b^1 . With the adjustment shown the pipe B^1 is to be used as a reservoir pipe for containing compressed air and conveying the

ame to the auxiliary reservoir D, and the other pipe B is the ordinary operating pipe for operating the brakes in the usual way.

It will be seen that by turning the cock d^1 one quarter way around the relation of the pipes B B¹ to the auxiliary reservoir D and the brake-cylinder C will be reversed, but that the operation otherwise will remain the same. I also so construct my apparatus that when a car leaves the track or becomes uncoupled from the train the brakes will be automatically applied by means of the compressed air which is stored up in the reservoir-pipe and the auxiliary reservoir.

For this purpose I connect the pipes B B¹ with each other near the ends of the car by cross-pipes E E¹. In two diagonally-opposite corners of the parallelogram thus formed I make cases e^1 for the three-way cocks e , though one such cock and case will suffice to perform the function in view. When the cars are running these cocks are both in the position shown at the upper right corner of Fig. 1, so as to leave a free communication through the pipes B B¹. Each cock e is provided with a handle or arm, which (by means herein-after described) is, when a coupling breaks or a car leaves the track, shifted so as to throw the cock to the position shown at the lower left-hand corner of Fig. 1, by which through communication is closed and the compressed air passes from the reservoir-pipe B¹ and auxiliary reservoir D around through the operating-pipe B and pipes B² b to the brake-cylinder C, and applies the brakes.

To give the cocks e this throw I have shown two devices, which are illustrated in Figs. 1, 5, and 6. In Fig. 6, e^1 represents the cock-case; e^2 , the stem of the cock e ; and e^3 , the shifting-handle, which, in this figure, is in the position it occupies when through communication is open. From a wrist on this handle e^3 a crank-arm, m , extends back to, and, by a catch m^1 , engages, a counter-catch, o . A spring, m^2 , or its equivalent, a weight, is arranged in connection with the crank-arm m , so that when the catch is released the arm will, by a forward throw, shift the position of the cock e , as above indicated. To effect this release I introduce under the arm m a tripping-head or lever, i , preferably of circular form, so that it will bear against the arm m whichever way it is moved, and from at or about its central point a tripping-stem, i^1 , extends downward such distance that when the car is on the track, it will clear the ground, but when the car leaves the track, it will strike the ground, the track, or ties, and, by a vertical, forward, or back or side motion, lift the arm m and disengage the catch with the result already stated. But to shift the position of the cock when the car-couplings break, while the car is still on the track, I run a cord or chain, y , or equivalent device from the outer end of the handle e^3 forward and attach it to the hose-coupling y^1 of that or the next car at such point forward of the "slack" that when the car-couplings break and the slack-hose is straightened out the handle e^3 will by the cord y , be drawn over far enough to shift the position of the cock e , as already explained. In this way the brakes are automatically applied, in case of accident, to any part of the train. The same wire or chain y , or another, may extend in like manner from the coup-

ling y^1 to the stem i^1 , or to any other device which will disengage the catch $m^1 o$ with like result to that already stated. A slot, x , is made in the forward or outer end of the arm m , in which the wrist of the handle e^3 plays, in order that the cock may be shifted by the wire y independently of the arm m . But other devices for automatically shifting the cock e may be employed; my present invention not being limited to those described. To the main reservoir A^1 is attached any suitable form of pressure-gauge, as shown at f , and to each brake-pipe $B B^1$ I attach a pressure-gauge of like suitable form $g g^1$, and arrange in convenient proximity to each an alarm-whistle $h h^1$. These gauges $g g^1$ and whistles $h h^1$ are for use in signaling. Each one has a graduated index (illustrated in Fig. 4) so constructed, with reference to the pressure of air in the pipes, that a certain amount or degree of pressure—say one-half pound per square inch—shall send the index finger s to the graduation 2; a pressure a little greater, to 3; and so on. By a system agreed on, each graduation indicates a separate order or message, as “flag station,” “stop for orders,” “danger—run slow,” “danger—stop,” &c.; the highest or last graduation, preferably, indicating “stop.” The gauge is so constructed that greater degrees of air pressure will not affect it. In each car a like gauge is arranged, as shown at g^2 , Fig. 3, and a pipe connection, n, n^1 , extends from it to the brake-pipes $B B^1$. This gauge is arranged at any suitable point in the car, and its pipe connections are fitted with a cock, 1201-1203 n^2 , which is accessible to the conductor, and of which he carries the key. These pipe connections $n n^1$ and cock n^2 are such that, on the cock n^2 being opened, the compressed air will be admitted from the reservoir-pipe (say B^1) both to the gauge g^2 and to the other or operating-pipe B , along which it will pass to the gauge g in the engineer's cab. The conductor opens the cock n^2 till the pressure of air has moved the index finger s to the graduation which indicates the order he wishes to give the engineer, and then closes it. The index finger on the engineer's gauge will, in like manner, be carried to the same graduation, and the alarm of the whistle will call his attention to it. By reversing the operation the engineer may communicate messages to the conductor.

I do not deem it necessary to describe more minutely the ports and passages leading from the pipes $n n^1$ to the gauge g^2 , as a suitable arrangement of such devices, on the function being known, can be readily made by those skilled in the art. Where one of the brake-pipes is always used as a reservoir-pipe, and the other as an operating-pipe, only one of the gauges $g g^1$ will be required, and, of course, it should be arranged on the operating-pipe.

It will be seen that the conductor, by fully opening the cock, in case of extreme danger, will be enabled to apply the brakes himself, as well as notify the engineer, since the air will flow over by the pipes $n n^1$ from the reservoir-pipe B^1 to the operating-pipe B , and thence to the brake-cylinders. Also, that if it be desired to communicate but a single order, the gauges $g g^1 g^2$ may be dispensed with, and the order be communicated by a whistle blast.

What I claim as my invention, and desire to secure by letters patent, is—

1. An air-reservoir arranged on each separate car in combination with an air-brake cylinder, D, and main reservoir A¹ on or near the locomotive, substantially as and for the uses set forth.

2. The combination of the pipes B B¹ B² B³ b b¹ with a suitable arrangement of ports for admitting air to the auxiliary reservoir D and brake-cylinder C, substantially as and for the uses set forth.

3. The cock d¹ having ports a a¹, and arranged relatively to the air-reservoir D, brake-cylinder C, and pipes B B¹, substantially as described.

4. A cock, e, arranged in an air-brake pipe, with a suitable arrangement of ports inside and an automatically-operating connection outside, whereby, in case of accident, a free communication will be opened from an auxiliary reservoir, C, to a brake-cylinder, D, and external communication be closed, substantially as set forth.

5. In combination with a pair of air-brake pipes, B B¹, a signaling apparatus consisting essentially of an alarm or index gauge, or both, on or near the engineer's cab, a pipe connection on or in one or more of the cars, from one pipe, B, to the other, B¹, and like means in connection therewith for regulating or fixing the alarm to be given, substantially as set forth.

In testimony whereof I, the said George Westinghouse, Jr., have hereunto set my hand.

UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Improvement in Valve Devices for Fluid-brakes.

Specification forming part of Letters Patent No. 141,685, dated August 12, 1873; application filed May 24, 1873.

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Pittsburg, in the county of Allegheny and State of Pennsylvania, have invented a new and useful improvement in valve device for fluid-brakes; and I do hereby declare the following to be a full, clear, and exact description thereof, reference being had to the accompanying drawing, which represents in section my improved valve device, designed to be used in connection with a system of brake-pipes, brake-cylinder, and auxiliary reservoir, for the purpose of applying the brakes on railway trains by means of fluid-pressure.

In the system of steam-power air-brakes heretofore described in various patents, provision is made for the flow of air or other fluid under pressure from the brake pipe or pipes into a reservoir arranged under or in connection with each car, and for applying brakes by allowing the compressed air thus stored up in each reservoir to pass into the brake-cylinder. In such combination a triple valve has been described of such construction and with such connections that, by a continuous pressure of air in the brake-pipe, communication was kept open thence to each reservoir and closed to the brake-cylinder, but kept open from the latter to the external atmosphere; and, also, by lowering the pressure of air in the brake-pipe, communication was opened from each reservoir to the brake-cylinder of the car, and all other communication closed.

My present invention relates to an improved construction of triple valve, by means of which this operation is more advantageously effected, and has more particular reference to the construction of devices by which a flow of compressed air from each auxiliary reservoir to its brake-cylinder can be regulated at pleasure, and thereby the brakes be applied with any desired degree of force less than the maximum.

To enable others skilled in the art to make and use my improvement, I will proceed to describe the same.

(Here follows diagram marked p. 1204.)

The valve-case G is of the form substantially as shown, so as to give a valve-chamber, G¹, into which at or near one end a port, G², opens, and at or near its opposite end a like port, G³, also opens. The same valve-case includes also a valve-chamber, H, with a communicating passage, B, and the air-port H' communicates with the valve-chamber H. The valve-stem g has a limited range of motion

in the chamber G^1 . At or near its lower end it carries a valve, a , which seats on the annular V-shaped seat a' by suitable packing on its lower face. A spring, g' , bearing against the cap of the valve-case G , and against the upper face of the valve-seat b , holds the lower valve a to its seat, when not raised therefrom by air-pressure. The flexible diaphragm n divides the valve-chamber G^1 into two parts. The outer edge of this diaphragm or ring n is compressed between an annular metallic ring, n' , and a shoulder on the valve-case; and the inner edge of said ring around the stem g is compressed between the different parts of the compound nut $c c'$, which nut is free to move vertically on the stem g , and the upper face c' of which is provided with a suitable packing, so as to make a tight joint when brought against the annular ring of the valve-seat b . Commencing at a point a short distance below the upper valve seat b , the stem g is turned smaller or reduced in size, as at e , and is also slotted, as indicated at e^1 . This reduction in the size of the stem g gives an annular air-port, e , by which communication is secured from the upper to the lower part of the valve-chamber G^1 . The compound nut $c c'$, which constitutes mechanically a piston, has a downward extension around the stem g , as shown at d , by means of which, in moving up and down on the stem g , it covers and uncovers the port e , and thereby closes and opens communication between the upper and lower parts of the valve-chamber G^1 . The lower end of the annular port e communicates with the lower part of the valve-chamber G^1 by means of ports e^2 , which may be made in any desired number. Across the slot e^1 in the stem g a cross-bar, s , is arranged, with its ends fixed in position in the adjacent walls of the nut c . From this slotted part e^1 a pin, s' , extends down through and lengthwise of the stem g into the chamber H . The lower end of the chamber H is fitted with a spring, h , which bears against the conical valve h^1 , having a suitable packing on its conical face. Such valve is arranged in its chamber so as to open and close the escape-ports h^2 . This valve is attached to a stem, h^3 , which, by means of wings of the usual form, causes the valve h^1 to move vertically in its chamber in opening and closing the ports h^2 . The pin s' is of such length and position that with the downward movement of the piston $c c'$ the cross-bar s will be caused to bear against its upper end and force its lower end against the stem h^3 of the valve h^1 , and thereby throw it from its seat and uncover the ports h^2 . The conical plug o is attached to the lower end of the stem g in such position as to enter the port o' , which connects the chambers G^1 and H ; but this plug o is of such shape as to graduate the size of the opening of the port o' , accordingly as it is raised more or less by the upward movement of the stem g . The valve-case described is, by the port G^2 , connected with the brake-pipes, by the port G^3 with the auxiliary reservoir, and by the port H' with the brake-cylinder. If air or other gas or fluid under pressure be admitted by the port G^2 , it will cause the piston $c c'$, with its diaphragm n , to be depressed or to slide down on the stem g until it occupies about the position shown. The cross-bar s will then have opened the valve h^1 , and the valve a will be

closed by means of the spring g' , or by fluid-pressure; also, the annular port e will open. In such case the air or other fluid will pass, as indicated by the arrows, from the upper part of the chamber G^1 , along the ports e e^2 , into the lower part of the chamber G^1 , and out at the port G^3 to the auxiliary reservoir, whereby the auxiliary reservoir will be charged with compressed air of such density as it may be desired to store up for the purpose of operating the brakes. At the same time, by the means already described, the valve h^1 is unseated, and thus a direct communication is opened from the brake-cylinder, through the port H' , chamber H , and ports h^2 , with the external atmosphere. The brakes are then off. As soon as the pressure on the upper and lower sides of the diaphragm n and compound nut c c' is equal, or nearly so, the spring h in the lower part of the case, acting against the valve h^1 through the stem h^3 , pin s' , cross-bar s , will cause the piston c c' to slide upward on the stem g , and thereby cut off communication through the annular passage e , and will seat the valve h^1 so as to close the escape-ports h^2 . Then, if the pressure above the diaphragm n be reduced by allowing a portion of the air to escape from the brake-pipes, the pressure of the air or other gas, acting back through the port G^3 on the under side of the diaphragm n , will raise the piston c c' against the valve-seat b , compress the spring g' , and, by raising the stem g vertically upward, will lift the valve a from its seat a' and thereby open communication from the chamber G^1 , through the port o , chamber H , with the port H' . The compressed air or other gas or fluid will then be free to pass from the auxiliary reservoir, through the ports G^3 , o' , and H' , to the brake-cylinder, so as to charge the same and apply the brakes in the usual way. The area of the opening through the port o' is regulated by the distance which the plug o is caused to move vertically upward. Hence, if the pressure be reduced but slightly at G^2 , the plug o will be raised but a short distance, and a small amount of compressed air or other fluid will be allowed to pass through and out at the port H' . When the equilibrium is thereby restored in the chamber G^1 , the valve a will resume its seat and close the communication. If the pressure in the upper part of the chamber G^1 be materially increased, the lower valve h^1 will be unseated, as already described, and an open communication be made from the brake-cylinder, through the port H' and h^2 , to the external atmosphere. By the use of the taper plug o , in the manner described, and by regulating, as can easily be done by the use of suitable cocks, the amount of pressure in the upper and lower parts of the chamber G^1 , it is easy to regulate the amount or density of the air which is permitted to flow through the port o' into the brake-cylinder, and consequently easy to regulate and adjust, at all times, the force with which the brakes are applied, and such force may be varied from the maximum power of the brakes down to the fractional part of a pound, in excess of ordinary atmospheric pressure.

The construction of the piston may be varied somewhat, provided its operation and function remain substantially unchanged.

What I claim as my invention, and desire to secure by letters patent, is—

1. The piston *c c'*, having separate and independently-operating connections to, and in combination with, a charging-valve, *a*, and discharging-valve *h'*, whereby the discharging-valve shall be closed at or before the opening of the charging-valve, substantially as set forth.

2. The pin *s'*, cross-bar *s*, and stem *g*, in combination with the piston *c c'*, valves *a* and *h'*, and plug *o*, arranged substantially as set forth.

In testimony whereof I, the said George Westinghouse, Jr., have hereunto set my hand.

1211 UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Improvement in Steam and Air Brakes.

Specification forming part of Letters Patent No. 144,006, dated October 28, 1873; application filed July 24, 1873.

To all whom it may concern:

Be it known that I, George Westinghouse, Jr., of Pittsburg, in the county of Allegheny and State of Pennsylvania, have invented a new and useful improvement in steam and air brakes; and I do hereby declare the following to be a full, clear, and exact description thereof, which, taken in connection with the accompanying sheets of drawings hereinafter referred to, forms a full and exact specification of the same, wherein I have set forth the nature and principles of my said improvement, by which my invention may be distinguished from others of a similar class, together with such parts as I claim and desire to secure by letters patent—that is to say:

In the specifications of patents obtained by me March 5, 1872, Nos. 122,404 and 122,405, and August 8, 1871, No. 117,841, were described various arrangements and constructions of pipes, valves, and apparatus, whereby compressed air could be made to operate brakes and communicate signals in a railway-train.

My present invention relates to an improved construction of the valves and pipe couplings employed in such apparatus.

(Here follow diagrams marked pp. 1208 & 1210.)

I will first describe my improved construction of valves, referring to figure 1, which represents a section of the valve-box. This valve-box has three chambers or compartments, and is provided with three valves, A, B, and C, united by one stem. The first or upper chamber communicates, by the end passage E, with the pipe by which compressed air is conveyed throughout the train, and, by the side passage F, with the auxiliary reservoir of compressed air. In this chamber there are two valves, A and B, on the same stem of which the upper valve, A, has a greater area than the lower valve, B, and has holes through it near its periphery covered by a disk, *a*, pressed against its back by a spring. The second chamber communicates, by a side passage, G, with the brake-cylinder, and the third chamber has an opening, H, to the atmosphere. This third chamber contains the third valve, C, also on the same stem, which can close upward against a caoutchouc or leather seating, *c*, when the valve A is closed against its upper seat. The seating *c* is made with a little space between its inner edge and the body of the valve-box, so that when the valve C bears against it the pressure of

the seating shall press it against the raised annular edge of valve C, and thereby insure the tightness of its closure.

The operation of these valves is as follows: Assuming that the primary reservoir is not charged with compressed air, when compressed air is admitted into the air-pipe it enters by the passage E, its pressure acting on the larger valve A, opens it and closes valve B. The compressed air thus admitted flows through the opening in the valve A, pressing away the disk *a* that covers them, by the passage F, to the auxiliary reservoir, which it charges. At the same time the valve C, being on the same stem with A and B, is opened, and air from the brake-cylinder issues, by the passage G, at the valve C and through the opening H to the atmosphere; and the brakes are taken off by relieving the piston in the brake-cylinder from pressure.

Now if it be required to put on the brakes, air is allowed to escape from the air-pipe, either by opening a cock or valve by hand or automatically, (in the manner described in the specifications referred to above,) when the air-pipe or its connections give way, or a carriage becomes detached or runs off the line. The auxiliary reservoir having been charged with compressed air, as described above, the pressure communicated through the passage F from the larger area of the valve A, and finding no escape by the holes in its periphery, which are closed by the disk *a*, raises the valve against its seat, and so closes communication with the air-pipe by the passage E. At the same time the valve B is opened, the valve C is closed. Compressed air then flows from the primary reservoir by the passage F, past the valve B, through the passage G to the brake-cylinder, where it acts on the piston so as to put on the brakes.

Thus, by means of this triple-valve arrangement, when the air-pipes communicating with E are charged with compressed air the primary reservoirs are charged and the brakes are taken off, and when air is discharged from the air-pipes, the brakes are put on by the action of the air stored in the auxiliary reservoir.

Fig. 2 represents a section of a construction of such a valve-box in which the lower disk-valve C is replaced by a sliding-ring valve, K. In this case the opening to the atmosphere is a side passage, H, and the communication to the brake-cylinder is at the end passage G.

Fig. 3 represents a sectional plan on the line X X. The ring K is a circular slide, which closes the opening H when the valve is retracted, and leaves it open, as shown in Fig. 2, when the valve is extended.

The ring is divided at one side to allow it to spring so as to make a tight fit in the cylindrical part of the valve-box in which it is seated, and a steady-pin, *k*, projecting into the slit of division prevents the ring from turning round. The ring is connected to the valve-stem by a pin, *l*, passing through the sides of the ring and the stem. The action is in this case the same as that described with reference to Fig. 1.

We have described the action of this valve arrangement as if it

communicated with only one air-pipe. By combining it, however, with double valves connected by a stem, such as have been described in the specifications above referred to, either or both of the duplicate air-pipes serve to work upon the auxiliary reservoir and brake-cylinder, as above described.

By referring to the before-mentioned specifications it will be seen that these double valves are of two kinds, one which opens the passage from the pipe of higher pressure and closes the passage to the pipe of lower pressure, and the other which closes the passage from the pipe of higher pressure and opens that to the pipe of lower pressure.

In connecting the duplicate air-pipe with the valve-box above described, and with the brake-cylinder, such double valves may be arranged in the manner shown in the diagram plan, Fig. 4. In this diagram A and B represent the two air-pipes, communicating throughout a train; R, the auxiliary reservoir; and C the brake-cylinder. T is the triple-valve arrangement, above described, and D is one of the double-valve arrangements described in the specification above referred to, whereby either of the pipes A or B, that contains air at lower pressure than the other, is cut off. It will be seen that compressed air conveyed along either or both of the pipes A and B will operate on the auxiliary reservoir R and the brake-cylinder C by means of the triple-valve arrangement T, in the manner above described.

Sometimes it is desirable that either of the two communicating air-pipes may be employed to charge the reservoir, while the other pipe may be used to operate the brakes. An arrangement of valves for this purpose is shown in the diagrammatic plan, Fig. 5, where A and B represent the two air-pipes; C, the brake-cylinder; R, the auxiliary reservoir; T, the triple-valve arrangement, above described; D¹ and D², double valves, such as that marked D in Fig. 4; and E, one of the other kind of double-valve arrangements, described in the former specification referred to above, whereby the pipe containing air at higher pressure is cut off from communication.

From this arrangement it will be seen that one of the pipes—such as A—may be employed to charge the reservoir R, the compressed air from A passing by the one end of E, and past one of the valves in D¹, acting on the large valve in T, so as to open it and the farthest valve, and close the middle valve of T, and passing the larger valve of T to the reservoir R. At the same time the other pipe, B, may be charged with compressed air for putting on the brakes, the air from that pipe passing the open valve *e'*, and thence by the pipe G to the valve-box D², where it will open the valve *d'* and close *d*, and thence to the brake-cylinders C, where the pressure will act on the piston so as to put on the brakes. If, now, the pipe B be relieved of pressure, then, the valve *e* being closed and *e'* being open, the air in the pipe G will have its pressure reduced. The valves *d* *d'* will then be in equilibrium, allowing the air from the brake-cylinder to escape past either or both of them, and either past the third valve in T to the atmosphere, or by the pipe G and past

the valve e' to the discharge-pipe B. Again, assuming the reservoir R to have been charged with compressed air, and the pipe B to be relieved of pressure, by relieving the other pipe A of pressure the brakes will be put on, for the valves in E and D¹ being then in equilibrium the pressure is taken off the large valve in T, which is therefore closed, opening the second valve in T and closing the third, so that compressed air will flow from R past the open valve in T, and opening the valve d and closing d' into the brake-cylinder C.

Two pipes communicating throughout a train may be applied in connection with valves in the manner represented on the diagram plan, Fig. 6. Here the one air-pipe A is shown with branches A' at each end of the carriage for convenience of coupling, as has already been described by me in the former specifications referred to. The other pipe, X, communicates with the triple-valve arrangement T. Assuming that X is charged with compressed air, it charges the auxiliary reservoir R, keeping open the large valve in T and the third valve, and closing the middle valve. Then compressed air admitted into the pipe A will open the valve d and close d' , and pass into the brake-cylinder C, so as to put on the brakes; and when air is discharged from A, the valves d and d' being in equilibrium, the air from C will pass either d into the pipe A or d' past the third valve in T to the atmosphere, and thus the brakes will be taken off. Again, the pipe A being relieved of pressure the brakes can be put on by discharging air from the pipe X, for then the larger valve in T and the third valve will be closed, and the middle valve will be opened, so that compressed air will flow from the reservoir R past the valve d' to the brake-cylinder C. The air can be discharged from X, either by a cock or valve opening, directly to the atmosphere, or by a cock, Y, in a branch connecting X with A.

In this case the air admitted from X to A may serve for signaling by sounding-whistles or working-gages connected to the pipe A in the manner described in former specifications referred to. Instead of one pipe, A, with branches A', as shown in Fig. 6, two pipes A and B, with a third pipe, X, may be employed, as shown in the diagram plan, Fig. 7. Here it will be seen that either of the pipes A or B can be employed to work the brakes, while X, when charged, is employed to charge the reservoir R, and when discharged to permit the air stored in the reservoir to work the brakes. The contents of the pipe X may be discharged into the atmosphere by a cock or valve, or into one of the other pipes, as A, by means of a branch provided with a cock or valve, the pipe A being thus rendered available for communicating signals. The three pipes A, B, and X may be employed with a combination of valves such as is shown in the diagram plan, Fig. 8, where F represents a double-valve arrangement, such as was described in previous specifications referred to, having the upper valve f of larger area than the lower valve f' . D is a double-valve arrangement like that described above and marked with the same letter, and G is a check-valve of any known description. It will be seen that the reservoir R can be charged from the pipe X, the valve f being opened and f' closed by the pressure of the air in the pipe X. At the same time

the brakes can be put on by charging either or both of the pipes A or B with compressed air, and taken off by discharging the air from both. Again, if the pipes A and B be closed, and air be discharged from X, the air stored in the reservoir R closes the valve *f*, opens *f'* and passes G to the brake-cylinder C, so as to put on the brakes, and also to charge the pipes A and B for communicating signals. In this case the check-valve G performs the function of the third valve C above described, and in such construction is the mechanical equivalent therefor, the valves *f f'* corresponding in function and structure to the two upper valves of Fig. 1.

It will readily be understood that the several kinds of valve arrangements described in this and in the former specifications referred to can be combined in many other ways, so as to effect the working of brakes and communication of signals according to various systems of operation.

The arrangements shown in the diagrams, Figs. 4, 5, 6, 7 and 8, described above, are given as examples of how such combination of valves may be made, and although in these, for the sake of distinctness, the several valves are shown as if they were fitted in separate chambers, it may be readily understood that they might be fitted into separate compartments of one valve-box, so as to secure greater simplicity and compactness of construction. The same features of construction and combination may be employed in connection with hydraulic gas or other fluid brakes. In connection with hydraulic brakes, an accumulator should take the place of the reservoir.

What I claim as my invention, and desire to secure by letters patent, is—

1. The combination of the triple valve A B C, seated as described, the valve-case connection E, above the valve A, to an air-supply pipe, a connection, F, between the valves A B with an auxiliary reservoir, a connection, G, below the valve B, with the brake-cylinder, substantially as set forth.

2. A triple valve arranged, in combination with a line of brake-pipe, auxiliary reservoir, and brake-cylinder, so that by the introduction of compressed air or steam the auxiliary reservoir will be charged and the brakes let off, and when the air is let off from such pipes an opening will be made from the auxiliary reservoir to the brake-cylinder, substantially as set forth.

In testimony whereof I, the said George Westinghouse, Jr., have hereunto set my hand.

UNITED STATES PATENT OFFICE.

W. DAVIDSON JONES, of Hagaman's Mills, New York.

Improvement in Air-brakes.

Specification forming part of Letters Patent No. 166,386, dated August 3, 1875; application filed July 27, 1875.

To all whom it may concern :

Be it known that I, W. Davidson Jones, of Hagaman's Mills, in the county of Montgomery and State of New York, have invented a new and useful improvement in automatic-supply relief-valves for operating compressed air-brake cylinders; and I do hereby declare the following to be a full, clear, and exact description thereof, reference being had to the accompanying drawings, making part of this specification, in which—

(Here follow diagrams marked pp. 1216 & 1218.)

Figure 1 is a side elevation of the valve. Figs. 2 and 6 are sectional views of Fig. 1, on the plane of the line xx in Fig. 5, showing the induction and eduction ports, the compound trunk-valve B B, and valve c on the stem c' , held to its seat $m m$ by springs 3 3. Fig. 3 is a transverse section of the end of trunk-valve B B, showing the passage a and valve-stem guide n . Fig. 4 is a transverse sectional view of the opposite end of the compound trunk-valve B B, showing the valve c and valve-stem guide n' . Fig. 5 is an elevation of the valve, looking at the ports h and k .

Like letters and figures of reference indicate like parts in each drawing or figure.

My invention relates to that class of compressed air-actuated car-brakes in which the air is conveyed back to reservoirs beneath each car by a pipe from a main reservoir on the engine, the compressed air from the auxiliary reservoirs on each car of the train operating a movable piston within a cylinder, thereby applying the brake-blocks to the wheels, as is commonly done. By the interposing of my invention in close connection therewith, and between or by its use forming the connections between the auxiliary reservoir, the cylinder containing the piston, and the branch-pipe from the main supply-pipe, the brakes may be rapidly and readily applied, and as rapidly and readily released, at the will of the engineer, or automatically set on all the cars of the train, should the cars become uncoupled, or the main supply or branch pipes become broken, as will be hereinafter fully set forth.

My improved automatic-supply relief-valve for connecting the branch induction-pipe with the auxiliary reservoir, and at the same time closing connections with the brake-cylinder, and at the will of the engineer (or in case of accident uncoupling of cars, or rupture of main pipe from the reservoir on the engine or tender) to close

such connections, and to automatically open connections between the auxiliary reservoir and the brake-cylinder, thereby allowing the compressed air to pass to said cylinder, actuating the piston thereof and applying the brakes, as is usually done, and as readily relieving the cylinder of the compressed air, and discharging it by opening communication from the cylinder with the atmosphere, and at the same time restoring the connection between the main supply-pipe and auxiliary reservoir by decreasing and increasing the pressure in the main supply-pipe running the whole length of the train.

My invention may be used to operate the pistons of brake-cylinders attached to each car where there is no auxiliary reservoir employed, and discharge the compressed air directly from the cylinder, after doing its work, into the atmosphere, without returning it to the engine through the supply-pipe, the same being done by simply cutting off the supply or pressure from the main supply-pipe.

To enable others skilled in the art to make and use my invention, I will proceed to describe its construction and operation.

A is a valve-case, made substantially as shown, and provided with a cap, A', containing the induction port or passage *y*, said port connecting with the main supply-pipe from the engine, and being also provided with eduction pipe or port *g*, to which is connected the auxiliary reservoir and eduction-induction port *k* communicating with the brake-cylinder, and eduction-port *h* communicating with the atmosphere. The cap A' is secured to the shell-case A by bolts 2.

The compound trunk-valve B, Figs. 2 and 6, is made of proper form, substantially as shown, having the circumferential depression *o*, Figs. 2 and 6, and valve-seat *m*, valve *c* on valve-stem *c'*, is held in position by valve-stem guides *n n*, Figs. 3 and 4. Said valve *c* is held to its seat *m*, Figs. 2 and 6, by spiral spring 3.

The operation of my invention is as follows: With the 1220 port *y*, Figs. 1, 2, 5, and 6, connection is made with the supply-pipe leading from the main reservoir on the engine. With the port *g* connection is made with the auxiliary reservoir. With the port *k* connection is made with the brake-cylinder, operating a piston within, and port *h* communicating with the atmosphere.

Compressed air being admitted from the main reservoir attached to the engine, through a three-way cock, into the supply-pipe and its branches to each car of a train, the compound trunk-valve B would be driven by the compressed air to the rear or lower end of the case A, and closing port *k* leading to the brake-cylinder, as shown in Fig. 2, the strength of the spiral spring 3 holding valve *c* to its seat *m* sufficiently firm to carry the compound trunk-valve B to the lower end, as shown in Fig. 2; the pressure would then unseat valve *c* on stem *c'* and allow the air to pass, through port *y*, passage *a*, and port *g*, into the auxiliary reservoir. The pressure in the auxiliary reservoir would be about equal to the pressure in the main reservoir and supply-pipes. The brake-cylinder would communicate with the atmosphere through port *k*, circumferential de-

ression *o*, and induction-port *h*, thereby leaving the piston free to return to the back of the cylinder by the action of the throw of springs attached to the brake-blocks, or through any other suitable agency.

When the engineer wishes to put on the brakes he turns the three-way cock near to him in the supply-pipe, cutting off communication with the main reservoir and opening communication with the atmosphere in that portion of the supply-pipe in rear or back of the three-way cock, thereby reducing the pressure in that portion of the supply-pipe and its branches leading to each automatic-supply relief-valve, which, by the excess of pressure retained in the auxiliary reservoir, would force a current of compressed air backward, closing firmly on its seat the valve *c*, Figs. 2 and 6, and driving the compound trunk-valve B into the forward part of valve-case A, as indicated by the dotted or broken lines in Fig. 2, and fully shown in Fig. 6, thereby opening full and free communication from the auxiliary reservoir, through ports *g* and *k*, into the brake-cylinder, thereby moving the piston, and, by suitable connections from said piston to the brake-blocks, applying the brakes.

When the train is stopped and the engineer wishes to take off or release the brakes, he turns the three-way cock so as to close communication with the atmosphere and open communication from the main reservoir on the engine with the supply-pipe, and to each automatic-supply relief-valve, which, by the excess of pressure in the main reservoir and supply-pipe over the reduced pressure of the expanded air in the auxiliary reservoir and brake-cylinder, causes a current of air to pass into the port *y*, Figs. 2 and 6, and, by the spring 3, holding valve *c* on its seat *m*, the compound trunk-valve B, Figs. 2 and 6, is driven from the position just described and fully shown in Fig. 6 to the position shown in Fig. 2, at the bottom or back end of the valve-case A, and simultaneously closing port *k* from communication with port *g*, Fig. 2, the compressed air from the supply-pipe unseats valve *c* and passing into the auxiliary reservoir until the equilibrium is restored, and, with the return of the compound trunk-valve B to the position shown in Fig. 2, communication is opened from the brake-cylinder, through port *k*, circumferential depression *o* on the compound trunk-valve B, and port *h*, Fig. 2, with the atmosphere, thereby allowing the air in the brake-cylinder to instantly escape, releasing at once, through the medium of the piston and connections, the brake-blocks.

It is evident that my invention can be used as a simple relief-valve, without any auxiliary reservoirs, by placing it between the brake-cylinder under each car and the branch-pipe leading from the supply-pipe, and making the following connections, that is, connecting the branch-pipe to the induction-port *y*, Figs. 2 and 6, and the brake-cylinder to port *g*, plugging port *h*, as shown in Fig. 5, by cross shading, to prevent dust and like matter from entering, as that port is not used.

The operation as a simple relief-valve is as follows: When the engineer wishes to put on brakes he turns the three-way cock in the supply-pipe, thereby closing communication with the atmosphere

and opening communication from the reservoir to each car through the supply-pipe and branch to port *y*, Figs. 2 and 6, forcing the trunk-valve B to the back end of the case A, thereby closing education-port *k*, as shown in Fig. 2, when the compressed air will unseat valve *c* and pass from the branch-pipe through port *y*, air-passages *a*, and port *g*, into the brake-cylinder, actuating the piston and putting on the brakes.

To release the brakes the engineer turns the three-way cock so as to close communication with the reservoir and open communication with the supply-pipe running back through the train with the atmosphere. As soon as the pressure in the supply-pipe is reduced the back-flow from the brake-cylinder commences, driving the compound trunk-valve B into the forward part of case A, as shown in Fig. 6, and opening communication from the brake-cylinder, through ports *g* and *k*, into the open air, thereby releasing the brake-cylinder piston and, through its connection, the brake-blocks.

The compound trunk-valve B may be packed at each end to prevent the leaking and injury, if so desired, and the valve-seat *m* may also be packed with suitable packing.

This supply relief-valve is automatic in its operation, is durable, and is free from liability to get out of order.

A stop-cock may be placed in the pipes leading from the auxiliary reservoirs to the valve-ports *g* on each car, so as to close the same in case a car is to be removed from the train to prevent the brakes from being set.

The port *h* may be placed on any side of the case A A', retaining its position lengthwise, without changing the nature of my invention.

The manner of its use and operation will be readily understood by those skilled in the art.

I am aware that it is not new in air-brakes to use a hollow piston-valve having a supplemental valve working therein, the latter opening against the pressure, and hence I make no claim to the same; but

What I claim, and desire to secure by letters patent, is—

The combination, with the valve-casing having ports *y*, *g*, *h*, and *k*, of the hollow piston-valve and check-valve inclosed therein, to open with the pressure, the ends of the piston-valve having perforated cross-bars to support the stem of the check-valve, substantially as and for the purposes specified.

W. DAVIDSON JONES.

UNITED STATES PATENT OFFICE.

H. LANSING PERRINE, of Freehold, New Jersey.

Improvement in Air-brakes.

Specification forming part of Letters Patent No. 166,405, dated August 3, 1875; application filed July 29, 1875.

To all whom it may concern :

Be it known that I, H. Lansing Perrine, of Freehold, in the county of Monmouth and State of New Jersey, have invented certain new and useful improvements in air-brakes, of which the following is a full, clear, and exact specification :

This invention is in the nature of an improvement in single-acting air-brakes, wherein each car is provided with an air-reservoir and a brake-cylinder, admission of air to both of which is controlled by an intermediately-located valve of peculiar construction, in such manner that, as air is being supplied through the pipes from the main reservoir at the locomotive, communication is open to the reservoir under each car, and cut off from the brake-cylinder, until the pressure in said reservoir equals that in the supply-pipes, when, if the pressure of air in the pipes is slackened or diminished, the valve opens the brake-cylinder inlet, and allows the air in the reservoir to escape into such cylinder and force on the brakes; and the invention consists in a tubular spring piston-valve operating in a chamber or shell having an inlet for the air, a reservoir-opening, and a combined supply and exhaust for the brake-cylinder, as hereinafter fully described.

Referring to the drawings,

(Here follows diagram marked p. 1224.)

Figure 1 is a top or plan view of an air-brake mechanism with my valve attached. Fig. 2 is a partly sectional view of the valve about full size. Fig. 2' is a side elevation of the front end of the valve open, or in position to allow air to flow into the reservoir. Fig. 3 is an end view of the valve in half-section and half-elevation. Fig. 4 is a sectional view of one end of the valve modified.

L represents a brake-cylinder, and I a reservoir, such as are usually attached to each car. A is a valve secured to or otherwise connected with said reservoir, and with the supply-pipe F, extending from the main reservoir on the locomotive, and further communicating with the brake-cylinder by a pipe, G. Within the casing or shell of valve A I make a chamber, A', and close its open end by a plug or nut, A''. In this chamber I make openings to receive the supply-pipe F and pipe G, leading to the brake-cylinder; also, an opening, H, leading into the reservoir. B is a valve having a

hollow center, in which a supplemental spring-valve, C, is placed, on which the valve B moves back and forth. The valve B is made in the form of a piston, with two heads, *b b'*, fitted with a peripheral steel or other packing, and connected by a stem of less diameter, and with a central cavity, in which fits the winged valve C. The valve C, near its rear end, is formed with a stop or shoulder, against which the valve B strikes in its backward movement, and is prevented from being forced back too far, whereby it might cover or close the reservoir-port H. This valve C has a packed flange or head, *c'*, for controlling the front of the opening in valve B, and said head is extended into a stem fitting into and guided by a socket, *a*, in the nut A'', and between said head *c'* and nut is arranged on the stem a coiled or other spring, E. The other end of the valve C is made with a head, *c*, between which and the piston B is arranged a coiled or other spring, D. In filling the reservoir air is turned into the supply-pipe, which, entering the valve, presses back the piston B, so as to force it away from the head *c'*, and allow the air to pass through the hollow valve B into the reservoir through opening H. The brake-cylinder port is then, between the heads *b b'*, cut off from communication with the reservoir and supply-pipe, and any air in said cylinder flows back through said pipe, and exhausts at port J. Now, when the pressure of air in the pipe F and reservoir is equalized, the supply may be withheld or withdrawn from said pipes, when the force of spring D, exerted against the valve B, will drive it up against head *c'*, and close said valve. This will carry head *b'* the other side of the brake-cylinder port, and establish communication between the reservoir and said brake-cylinder, and set the brakes. The spring E serves simply to insure an easy and accurate working of the valves B C.

It will be seen that the valves B C combine to make a double-acting valve with relation to the reservoir and cylinder.

When the brakes are to be let off, the air is turned into the pipes F, and the first-described operation repeated, springs or other means being employed to retract the brakes.

1226 The modification illustrated in Fig. 4 shows ports *g g'*, for supplying air to the cylinder. Port *g* is controlled by head *b'*, and port *g'* by a winged plunger, P, working in a recess at right angles to said port, and operated by its connection with valve C. This insures a quick supply to the cylinder, and the spring E can be dispensed with.

Provision for any necessary movement of valve C is made by extending the socket *a*. It may be necessary to make an opening or way, *e*, leading from the reservoir to the front of the valve-casing, in order to insure the equalization of pressure on the piston-valve that may be lacking by reason of leakage in the pipes or elsewhere.

I am aware that it is not new in air-brakes to use a hollow piston-valve having an inclosed check-valve opening with the pressure, and, therefore, I make no claim to the same; but,

Having thus described my invention, what I claim is—

The combination, with the valve-casing, having ports arranged substantially as described, of the hollow piston-valve and a supplemental wing-valve, the latter, when serving to admit air to the reservoir, opening against the pressure, as and for the purpose set forth.

To the above specification of my invention I have signed my name this 29th day of July, A. D. 1875.

H. LANSING PERRINE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Improvement in Air-valves for Power-brakes.

Specification forming part of Letters Patent No. 168,359, dated October 5, 1875; application filed August 19, 1875.

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Pittsburg, county of Allegheny, State of Pennsylvania, have invented or discovered a new and useful improvement in air-valves for power-brakes; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, reference being had to the accompanying drawing making a part of this specification, in which—like letters indicating like parts—

(Here follow diagrams marked pp. 1228 & 1230.)

Figure 1, sheet 1, is a longitudinal and vertical sectional view of a valve-case, valves, connections, and ports, illustrative of my improvement. Fig. 2, sheet 2, is a transverse section thereof through $x x$, Fig. 1. Fig. 3, sheet 1, is a detached sectional view of the cock and connecting-ports; and Fig. 4, sheet 2, illustrates in outline the arrangement of my improved valve device in a system of air-brake apparatus.

My present improvement is particularly designed for use as a part of a system of brake apparatus now generally known as the Westinghouse automatic brake, and consists of certain improvements in the devices by the agency of which the flow of the compressed air, both as to direction and amount to and from the auxiliary air-reservoirs and brake-cylinders, is effected and regulated; and it further consists in the incorporation of suitable devices, by means of which the parts peculiar to the automatic system of operation are thrown out of operation or cut off, so that the brakes shall be set or put on by the direct admission of air from the brake-pipe to the brake-cylinder.

The valve-case D is made of cylindrical form, for the most part, though of different diameters at different points, as shown. It incloses a piston-chamber, a , a valve-chamber, a^1 , and a communicating passage, a^2 . A screw-cap, D^1 , closes its larger end. In the periphery of this cap I cut an annular air-groove, c , from which a series of radial air-ports, c' , in any desired number, open into an annular space, a^3 , which latter opens directly into the piston-chamber a . This cap has a tubular extension, d , into the outer end of which I screw a stem-guide or bush, d^1 . The upper end of the bush affords a bearing for one end of a spiral spring, d^2 , which latter, at its opposite end, bears against a collar, d^3 , on the stem d^4 , so as to hold the stem up when not depressed, as hereinafter described.

One end of the stem d^4 passes through a suitable aperture in the cap D^1 and enters the piston-chamber a , and the other end is guided in the tubular aperture of the bush d^1 .

From the valve-chamber a^1 a side port, R , leads by suitable pipe connections to an auxiliary reservoir, R' , of the usual or any suitable construction. In this chamber is a slide-valve, H , from beneath which a port, e , leads through a bracket-arm, B , in which is formed a cock-case, and through a cock, B' , arranged therein by a port or passage to a coupling, C , from which, by suitable connections, communication is effected with the usual brake-cylinder C' . Another port, e^1 , leads from the valve-chamber a^1 to the external air, and these ports e e^1 are in such proximity at their valve-chamber ends that they be brought into communication, or one cut off from the other, by the movement of the valve H . This valve is kept from revolving by means of a pin, h , entering a groove in its back or top, or by other suitable means, and is fitted with any desired known appliances for adapting it the better for its work.

The piston-chamber a contains a piston, G , suitably packed by a leather or metallic ring or rings, i , such as will give a close joint and work with small friction. From its upper side a stem, g , leads to and carries the valve H , and the upper extended end h' of the stem is guided, if need be, in a tubular socket made in the upper cap D^2 , which closes the upper end of the case D . Hence the valve H is operated by the piston G . The lower face of the piston has a V-shaped seat, v , which, at the lowest possible point of the down-stroke of the piston G , seats on a rubber seat, v' . On the upper side of the piston G I make an annular valve n , and a seat, n' , on the case, so that these shall come together and close direct through-communication, or prevent leakage when the piston G is at its highest point of stroke. When in this position, however, it

1232 uncovers a port, s , which is made in the case D , so as to make an open communication from one side of the piston to the other. The air passing through this port then enters the space a^4 above the piston, and thence passes by one or more radial ports, s^1 , into the annulus s^2 , and thence along the communicating passage a^2 , and out by the port R , to the auxiliary reservoir R' .

The introduction of compressed air from the brake-pipe is effected by suitable pipe-connection through the coupling B^2 . A port, b^1 , leads thence by a groove, b^2 , in the face of the plug B^1 to an air-passage, b^3 , made along the side of the case D , which passage, b^3 , opens into the annular groove c . The plug or cock B^1 is made to revolve in its case or seat, for purposes presently to be explained. The arrangement of its communicating passages being shown, its construction in other respects is such as is well known in the art. The coupling-port shown at P is simply made for convenience, and is to be closed by an ordinary screw-plug.

The devices thus described are arranged on each car with an auxiliary air-reservoir, R^1 , for containing compressed air stored up and ready for use, and also with a brake cylinder, C^1 , for applying the power by the usual piston and stem. When used as a part of the automatic apparatus the cock B^1 is kept in the position shown.

The engineer by his pump keeps up the desired air-pressure, and allows this pressure to be transmitted back, so that entering the coupling B^2 it shall pass, by the ports and passages $b^1 b^2 b^3 c e^1 a^3$, into the piston-chamber a , and by its pressure on the under side of the piston G shall seat it upward, as shown, and at the same time bring the valve H into the position shown. The compressed air, while still holding the valve G up, will pass, by the ports and passages $s a^4 s^1 s^2 a^2 R$, into the auxiliary reservoir R^1 , so as to charge it and keep it charged at a working pressure. The valve H at the same time covers the ports $e e^1$, so that none of the compressed air thus introduced can escape through either; but such ports $e e^1$ being then and thereby brought into communication, any air in the brake-cylinder C' above atmospheric pressure will escape, by $C e^2 b e e^1$, to the external atmosphere. The brakes will then be off, and the train in running condition.

Now, to apply the brakes with full force, the engineer, by opening a cock or valve in the brake-pipe, reduces the air-pressure therein, say, fifteen pounds per square inch, more or less. The pressure is then reduced in chamber a to a corresponding amount. Back pressure from auxiliary reservoir R^1 then depresses the piston G , so as to pass and cut off the supply-port s , and shifts the valve H , so that it shall uncover the port e , but cover e^1 . Then the stored-up air in R^1 will pass the end of the valve H , and, by the ports and passages $e b e^2 C$, will go to the brake-cylinder C' , and by shifting the piston therein apply the brakes in the usual way. By restoring the pressure in the brake-pipe the engineer shifts the piston G up again to its upper seat, so as to reopen the line of supply-ports, and shifts the valve H to the position shown, so as to cut off communication from the auxiliary reservoir to the brake-cylinder, but open communication from the latter to the external atmosphere, as already described. The brakes are thus released. When the engineer wishes to apply the brakes with less than the maximum power he reduces the air-pressure in the brake-pipe a correspondingly less amount.

The position of the piston G in its chamber a is regulated chiefly by variations of air-pressure on its opposite sides, and by lessening or increasing slightly the air-pressure in a below the piston the position of the piston may be changed at pleasure, and with it, of course, the valve H .

It will be observed that the valve H has at h^2 a length and breadth of face such that it may entirely cover the port e . Hence the piston G may be brought down so that while entirely closing the supply-port s it shall bring the valve H to a position where it shall uncover only a small part of the port e , or any desired part. Then as soon as the desired amount of air-pressure has passed through e to the brake-cylinder a slight upward movement imparted to the piston G will cause the valve-face h^2 to cover entirely the port e , and remain in that position, so that the air already thus admitted to the brake-cylinder will be retained there, and the brakes will be held to the wheels with a corresponding force. By again lowering the piston G and with it the valve H this force may be increased by an

additional charge of compressed air; or by a farther upstroke the ports e and e^1 may be brought into communication, and the brakes so be released.

In order to render this operation of graduating the air-pressure in the brake-cylinders more easy and certain I employ the stem d^4 and spring d^2 , with a degree of power in the spring approximately equal to the weight and friction of the piston and valve, and so arranged that when the desired amount of air-pressure has passed into the brake cylinder through the port e , and the air-pressure on the piston G is about the same above and below, the spring and stem will almost instantly shift the valve H so as to cover the port e and retain the pressure in the brake-cylinder. For practical purposes I deem it best that the stem d^4 should be of such length that the piston will engage it when the slide-valve H covers the port e , so as to cut off the supply of compressed air to and exhaust from the brake-cylinder. This pressure may then be increased or decreased at pleasure in the manner already described.

As water is sometimes condensed in the operations described, I provide for getting rid of it by a drain-port, g , and a drip-cup, g' , screwed onto the lower end of the bush d^1 .

1233 & 1234 As it sometimes happens that a car fitted up with the automatic apparatus is on a connecting line, made up into a train, the other cars of which are furnished with apparatus substantially such in some or all material features as that described in patent granted me April 13, 1869, it is important to convert the former into the latter. For this purpose I use the cock B^1 . By turning it, as in Fig. 3, so that the port or groove b shall communicate at its opposite ends with the ports e^2 and b^1 , it will be seen that all the rest of the apparatus will be effectually cut off, and a direct passage-way be made from the brake-pipe to the brake-cylinder. The compressed air is then turned on and turned off in applying and releasing the brakes in the manner generally practiced in that system of apparatus. Also, as it sometimes happens that the brake apparatus of a car will get out of order, so as to be inoperative, I provide for cutting off such car in such emergency by bringing a full side of the cock B^1 opposite the port b^1 , which will prevent all ingress of compressed air; and in detaching a car from a train where the automatic brake is in use I provide against the application of the brakes by leakage or escape of the air from the chamber a by means of the same cock B^1 . For this purpose I shift it to the position shown in Fig. 3, or to any other position which will prevent the air in the reservoir R' from being charged into the brake-cylinder C' ; and for the purposes described any suitable form of four-way cock may be substituted, in combination with the same, or a substantially-like arrangement of ports.

The forms of the valves, ports, and communicating-passages, and to a certain extent their arrangement, may be changed, and all such modifications of the apparatus described as include a piston and slide-valve, operated by air-pressure, for charging alternately and successively an auxiliary air-reservoir and brake-cylinder, and do not materially depart in their combinations and modes of operation

from what is above set forth and hereinafter claimed, I hereby include as within the scope of my invention. Also, the reversible cock B' , with an arrangement of ports substantially such as described, may be used in connection with the automatic triple valve now in common use, or other like apparatus, the combination and function remaining in this respect substantially the same.

One reason for using and preferring a slide-valve, H , which may be of any known suitable construction, instead of a piston-valve, is that the former does not require any packing, and may be worked with less friction. I have found that any considerable amount of friction interferes seriously with that ready, accurate, and certain motion of the valve which is required in this kind of a device for the purpose set forth.

I claim as my invention—

1. In an air-brake apparatus, a moving piston arranged in the line of air communication, operated by air-pressure, and a slide-valve, H , connected therewith, in combination with suitable air ports and passages leading to an auxiliary reservoir and brake-cylinder, whereby such reservoir and cylinder will be charged with compressed air alternately and successively by the throw or motion of the piston and valve, substantially as set forth.

2. The port s , in combination with air chamber a , piston G , slide-valve H , and auxiliary reservoir and brake-cylinder ports, arranged substantially as set forth.

3. The slide-valve H , in combination with an air-reservoir and brake-cylinder, arranged and operative substantially as set forth.

4. In combination with the piston G , a suitable line of ports and passages, $s\ a^4\ s^1\ s^2\ a^2$, for supplying compressed air to the auxiliary reservoir while the piston is on its upper seat, substantially as set forth.

5. In combination with a piston, G , operated by air-pressure, a stem d^4 , and spring d^2 , substantially as set forth.

6. The port q in an apparatus substantially such as described, for draining off the water of condensation from the air chambers or spaces to a drip-cup, q' .

7. A reversible four-way cock, in combination with a single line of charging-pipe and supply-port therefrom, a brake-cylinder port, and ports leading to and from suitable automatic devices, substantially as set forth, whereby either of the modes described of operating the brakes may be employed at pleasure without changing the port of supply.

8. An arrangement of ports $b\ b^1$ in the cock B' , ports b^3 and e , communicating with the automatic apparatus, and ports $b^1\ e^2$, communicating with the brake pipe and cylinder, substantially as set forth.

In testimony whereof I have hereunto set my hand

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Improvement in Air-brake Valves.

Specification forming part of Letters Patent No. 172,064, dated January 11, 1876; application filed December 18, 1875.

To all whom it may concern:

Be it known that I, George Westinghouse, Jr., of Pittsburg, county Allegheny, State of Pennsylvania, have invented or discovered a new and useful improvement in air-brake valves; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, reference being had to the accompanying drawing, making a part of this specification, in which—like letters indicating like parts—

(Here follows diagram marked p. 1236.)

Figure 1 is a longitudinal sectional view of my improved valve; and Fig. 2 is a transverse sectional view through the line *x x*, Fig. 1. My present invention relates to an improvement in the valve device patented to me October 5, 1875, by patent No. 168,359. It is intended for the same purpose as therein set forth, performs the same function, and includes only such changes in construction and operation as hereinafter set forth.

The valve-case D is the same, inclosing a like piston chamber, *a*, valve-chamber, *a*¹, and communicating passage *a*²; also the screw-cap D', with its air grooves and ports, and tubular extension *d*, and stem-guide *d*¹; also the stem *d*², with its collar and spring; also the piston G, with its stem *g*, valve H, cock B', and the passages and ports which lead from and to such valve and cock, and from and to an auxiliary reservoir, brake-cylinder, and brake-pipe.

All these devices, having by the prior patent become a part of the prior state of the art, need not here be more fully described.

My present improvement dispenses with the side port *s* in the valve-case, and provides for an air-port (herein also lettered *s*) directly through the piston G, with one or more lateral ports *s*¹, opening into the passage *a*². The end of the port *s* next the chamber is made large enough for the insertion of a stem, *c*, of a somewhat less diameter, such stem *c* being connected by an enlargement, *c*¹, to the end of the stem *d*². The smallest part *c* of this compound stem is of the diameter of the smaller part of the port *s*, (or preferably a little less,) so that as the piston G makes a downstroke, *c* will enter the smaller part of *s*, and clean out any dust, dirt, or other obstruction which may have lodged therein.

The enlargement *c*¹ of the compound stem is of such length, size, and position relative to the piston G and the adjacent end of the port *s* that when the devices are in the position shown, (the brakes

then being "off" and the train in running condition,) such s will be open for the free passage of air from the brake-pipe to the auxiliary reservoir; but with a diminution of air-pressure in chamber a the back pressure of air from the auxiliary reservoir will shift the piston G, so that the port s , slipping onto the enlarged part c' , will be closed thereby, and the escape of air cut off in advance of the opening of the communication from the auxiliary reservoir to the brake-cylinder; and that this may be done without having to overcome any resistance from the slide-valve H, I make the distance between the collars e and e' a little greater than the length of the valve, as shown. Hence the port s will be closed before valve H begins to move for applying the brakes, and will be closed until the valve H shall have been brought back to the open position for a full release of the brakes. Consequently the valve can be operated as may be desired in applying and releasing brakes, and in graduating the brake-pressure, without leakage or loss at the air-supply port s , and with such port always closed.

As the piston G continues its stroke it engages the end of part d^4 of the compound stem, with the operation and result shown in the patent above cited.

It is not necessary that the port s should be of a reduced size at any point; but I prefer to make it as small as practicable for applying the amount of compressed air desired, in order that there may be as small an escape as possible when the back pressure on the piston G is brought into effective operation.

I claim herein as my invention—

1. The sliding piston G, having an air-port s , closed and opened by sliding onto and off of a stem, c' , and in combination therewith substantially as set forth.

1238 2. The sliding piston G, having an air-port, s , in combination with the compound stem c and c' d^4 , substantially as set forth.

3. The slide-valve H, made shorter than the distance between end bearings, in combination with the port s and stem c' , relatively arranged with reference to the operation of the valve H, while port s is closed, substantially as set forth.

In testimony whereof I have hereunto set my hand.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Improvement in Automatic-brake Relief-valves.

Specification forming part of Letters Patent No. 217,838, dated July 22, 1879; application filed May 21, 1879.

To all whom it may concern:

Be it known that I, George Westinghouse, Jr., of Pittsburg, county of Allegheny, State of Pennsylvania, have invented or discovered a new and useful improvement in automatic-brake relief-valves; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, reference being had to the accompanying drawings, making a part of this specification, in which—like letters indicating like parts—

(Here follows diagram marked p. 1240.)

Figure 1 is a vertical sectional view of a relief-valve applied to and combined with a coupling of the class described in reissued patent No. 8291, granted to me June 18, 1878. Fig. 2 is a horizontal section thereof through the line xx of Fig. 1. Fig. 3 is a vertical sectional view, showing the relief-valve applied directly to a ported diaphragm in the pipe; and Fig. 4 shows in outline the main elements of an automatic brake of the kind or class to which the present invention is particularly applicable.

The present device is more especially designed for use with and as a part of brake apparatus of the class commonly represented by the Westinghouse automatic brake, in which the brake-power available for immediate use in the brake-cylinders is contained in auxiliary reservoirs, one under each car. The brake-pipes are also kept full of air under pressure, in order to keep the reservoirs fully charged, and the charge of compressed air in the auxiliary reservoirs is brought into action in the brake-cylinders by opening an escape-port leading from the brake or communicating pipes to the external air. A like effect follows when the train separates, or couplings become disconnected, or other accident ruptures or opens the air-conduit pipes. The brakes are then automatically applied.

Such an apparatus is partly shown in outline in Fig. 4, wherein m represents one of a series of brake-cylinders; m' , an auxiliary reservoir. n is the valve which governs the flow of compressed air from reservoir to cylinder, and from cylinder to escape. $p p$ are the brake-pipes; h , the hose, and r the couplings. The main reservoir and operating-cock on the locomotive are of the usual construction. The relief-valves are represented at $v v'$.

It sometimes happens with such brake apparatus, especially in case of accident, that material advantage could be effected by having all the brakes of the train applied or brought into action simul-

taneously, or as nearly so as possible. To accomplish this it is only necessary to make provision for the simultaneous opening of one or more ports in the air-conduit passages at points not remote from each auxiliary reservoir. For this purpose I arrange at such various parts of the air-conduit or communicating pipes as may be desired, but by preference at the couplings, relief-valves of the kind shown in the drawings. In the construction there shown the valve-box forms a part of the coupling itself.

The aperture A of the valve-box is seated in the lateral port-opening of the coupling R, so as to come in the line of the flow of air through the brake-pipe, hose, and couplings.

The aperture A communicates with the port of the next half-coupling, and the aperture B leads to hose and brake-pipe. A third aperture, C, opens to the external air.

Within the valve-box is a piston, D, with holes *d* through it, covered by a valve, E, held down by a spring, *e*. On the stem of the piston is fixed a valve, F, which covers the aperture C.

When compressed air enters the valve-box by the aperture A from the front portion of the communicating pipe, it raises by its pressure the valve E, passes through the holes *d* in the piston D, keeps the valve F closed, and passes on by the passage B' and aperture B to the hinder part of the pipe to charge the auxiliary reservoirs, in the usual way. But should the pressure in the front part of the pipe communicating with A be reduced intentionally or by accident, then, the valve E closing the holes in the piston D, that piston is pressed down by the pressure from B, and the valve F is drawn from its seat, leaving the orifice C open for the escape of air from the hinder portion of the pipe which communicates with B; and by giving the piston D and valve E a sufficient length of stroke or motion, such that it will drop below the shoulder *s*, an open passage-way will be formed for the escape of fluid-pressure from the enlarged space or port *s*¹ to *s*², and thence out at C. In this
1242 way provision is made for the escape of fluid-pressure through C from the brake-pipes both forward and back of the couplings.

By arranging such valve-boxes at several points along the communicating pipe, each section of that pipe becomes relieved from pressure almost immediately on the section in front of it being relieved, and consequently the several sets of brakes throughout the train are put in action without the loss of time which would be involved if, for the relief of pressure throughout the pipe, the air contained in the hinder portions of it had to flow all the way to the escape-aperture, which might be near its front part, and is usually on the locomotive.

The same device may be applied at any part of the communicating pipes *p* by making therein, across the bore of the pipe, a ported diaphragm, *o*, Fig. 3, such as is used in ordinary stop-cocks, and arranging therein a relief-valve of the construction described, as shown in said Fig. 3; and so far as relates to the relief-valve, the ported diaphragm *o* and the ported part R² of the coupling are the mechanical equivalents each of the other. The form or construc-

tion of the relief-valve, its function and operation being substantially retained, may be varied considerably, in so far as it is an element in the described combination, without any material departure from the scope of the invention.

I am aware of the prior use of escape-valves, in combination with brake-cylinders, for the purpose of effecting a reduction of the working-pressure in such cylinders; but in the present invention the escape-valve enters into combination not only with the brake-cylinder, but also with the auxiliary reservoir, and in such a manner as to secure a result the reverse of that just stated—viz., to facilitate the charging of the compressed air from the auxiliary reservoir into the brake-cylinder.

I claim herein as my invention—

1. In combination with the brake-cylinders and auxiliary reservoirs of an automatic-brake apparatus, a ported diaphragm arranged in the line of fluid-pressure communication, and a valve device, which, under operative fluid-pressure, closes the external air or escape port, and opens a through passage-way for the air, and on the reduction of air-pressure in the main air-conduit, by accident or otherwise, will open the escape-port, substantially as set forth.

2. A relief-valve applied directly to and made as a part of a coupling, the combination of such two elements being substantially as described.

3. The valves E F, and ported piston D, in combination with ports or ways A B C, substantially as set forth.

In testimony whereof I have hereunto set my hand.

Improvement in Regulating-valves for Automatic Brakes.

Specification forming part of Letters Patent No. 220,556, dated October 14, 1879; application filed September 17, 1879.

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Pittsburg, county of Allegheny, State of Pennsylvania, have invented or discovered a new and useful improvement in regulating-valves for automatic brakes; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, reference being had to the accompanying drawings, making a part of this specification, in which—like letters indicating like parts—

(Here follow diagrams marked pp. 1244 & 1246.)

Figure 1, sheet 1, is a vertical sectional view of the triple-valve device illustrative of my improvements. Fig. 2 is a transverse horizontal section in the line *xx* of Fig. 1. Fig. 3 is a detached sectional view of the slide and auxiliary valves, valve seats, and stems, as shown in Fig. 1, but with the auxiliary valve in a different position; and Fig. 4, sheet 2, by a view similar to Fig. 1, illustrates some modified features of construction.

In the class of fluid-pressure brakes for railway-trains commonly known in this country as "automatic brakes," a device usually termed a "triple valve" is extensively used. This device, in two of the many forms in which it has been patented, is shown and described in United States patents granted to me October 5, 1875, No. 168,359, and January 11, 1876, No. 172,064, as well as in various other earlier and later patents.

It is important in such device that the valve (lettered H in said two patents and herein) which governs the flow of air or other fluid shall move not only with great certainty to any desired position, but also shall move with slight variations of pressure on the piston, (lettered G,) so that the application of the brakes with any desired power, and their ready release, may be quickly and easily effected at the pleasure of the engineer.

To this end I combine with the said valve H, giving it a slight range of motion on its stem, an auxiliary valve operated by the same stem, in such manner that a portion of the functions performed in said patents by the valve H may now be performed by such auxiliary valve, the latter moving with practically no resistance, and hence moving more quickly and with less pressure than the valve H itself. The same auxiliary valve is also designed for use, under certain circumstances, as a leakage-valve. In the drawings I have shown it as applied to or embodied in a triple valve

having the graduating-stem and spring of said patents, and also as used without them. The former will be first described with reference to Figs. 1 to 3.

A represents the valve-case, made preferably in two parts, united by the necessary number of screw-bolts A^1 , with interposed packing A^2 .

B is a drip-chamber; B^1 , the cylinder in which the piston G is operated, and B^2 is an upper chamber, through which the fluid passes under pressure to the auxiliary reservoir by the port R, or to the brake-cylinder by the port C. It is also a valve-chamber for the slide-valve H, which is secured on the stem, in any suitable way, by a pin, n^1 , going through the back U-shaped wings of the valve, and is held to its seat by any suitable spring, as at n , and rotation on the stem is prevented by a stud, n^2 .

A cock, K, with ports $k k'$, is arranged in the line of fluid-pressure communication, substantially as represented, and for purposes which will be understood by reference to said patents.

From the port P connection is made with the brake-pipe, and from the port C with the cylinders. With the devices in the position shown in Fig. 1 the brake apparatus is in the normal condition for the running of the train. The fluid-pressure then enters the port P, passes by $k P'$ into chamber B, through port b into B^1 beneath the piston G, and holds the latter up in the position shown. It then passes through ports $a a^1 a^2$ into chamber B^2 , and thence to the auxiliary reservoir through port R.

The details of construction and the functions of these parts will be readily understood from the drawings and the patents above named.

The graduating-stem b^1 and spring b^2 , including the reduced upper end of the stem, have also the construction and operation described in the second of said patents.

The piston-stem g operates the valve H; but the collar g^1 and shoulder g^2 , which bear on the opposite ends of the valve or
1248 its connections and give it its motion, are a little farther apart—say about one-eighth ($\frac{1}{8}$) of an inch, more or less—than the distance between the end bearings of the valve H.

The distance between the open end of the port a and the shoulder a^3 on the stem b^1 , when the piston G is at the highest point of its stroke, is by preference somewhat less—say one-sixteenth ($\frac{1}{16}$) of an inch, more or less.

The valve H has a cavity, s , long enough to uncover the port C and the exhaust-port E and put them in communication. It has also two additional ports, $s^1 s^2$, the former having a diameter, by preference, of about three-sixteenths ($\frac{3}{16}$) of an inch, and the latter of about five-sixty-fourths ($\frac{5}{64}$) of an inch, in a device of the proportions shown; but I do not confine myself in my invention to these exact figures or proportions, but include all such variations therefrom as give substantially a like construction and operation.

The distance between the ports s and s^1 is equal to or slightly in excess of the diameter of the port C at the valve-seat. The port s^1 communicates by a passage, c , with the open end of the valve H.

Transverse to this passage, and opening therein, is a cross-port, c^2 , Fig. 3, extending to the exterior of the valve H on one or both sides. Between the point of junction of this port with the passage c and the port s^1 , I make a valve-seat, e , and seat thereon a valve, e^1 , the stem e^2 of which is connected by a pin, e^3 , with the stem g .

It will now be seen that any motion imparted to the piston G, Fig. 1, will, through the stem g , be first operative in unseating the valve e^1 , the valve H being held by frictional contact with its seat, so that the stem g will slide through it until the collar g' engages the upper end thereof. Also, after any portion of an up or down stroke is made by the piston G, the first motion thereof in an opposite direction will first shift the auxiliary valve e^1 to or from its seat, as the case may be, before any motion is imparted to the valve H.

In order now to apply the brakes fluid-pressure is allowed to escape from below the piston G by the manipulation of the cock on the locomotive or other escape-cock. Fluid-pressure then acts back from the auxiliary reservoir on top of G, and forces it down, first closing the port a , and at the same time unseating the valve e^1 , and bringing the latter and the devices immediately connected therewith into the relative positions shown in Fig. 3. But a very slight reduction of pressure below G is required in order to do this. The downstroke of G is continued, shifting the valve H downward rapidly or slowly, until the port s^1 comes partly or fully into line with C.

The escape at E is then closed, and the ports and passages are open for fluid-pressure to pass from the auxiliary reservoir by R, c^2 , c , s^1 , and C to the brake-cylinder and cause the application of the brakes. In this motion of H, however, it should be noted that the small port s^2 is, while passing the open end of C, in communication with the exhaust E; but the amount of air thus escaping through a port so small is practically inappreciable, and does not interfere with the action described. When now the valve H is thus shifted, so that the port s , shall, to the extent of one-quarter or one-half its capacity, more or less, as is usual when less than a maximum braking force is desired, be thus brought into communication with the port C, and held there until the limited or desired amount of fluid-pressure shall have passed into the brake-cylinder, the auxiliary valve e^1 becomes available as a quick and ready means of closing the supply-port with certainty, without danger of opening the exhaust. To this end a very slight increase or excess of pressure below the piston G—much less, in fact, than is necessary to shift the valve H—will suffice to move the piston G and stem g far enough to close the valve e^1 on its seat e . All ports are thus closed by an almost instantaneous motion, and the brakes remain on with a force corresponding to the amount of pressure previously charged into the brake-cylinder.

In case a slight addition to the operative braking force is desired, either to compensate for loss by leakage or for any other reason, it may be secured by a slight downward motion of the piston G, such as will unseat the auxiliary valve e^1 . In this manner the graduating friction may be more advantageously performed than heretofore.

But the use of this auxiliary valve enables me to dispense entirely with the graduating stem and spring, and in this combination it is illustrated in Fig. 4, sheet 2.

With the valve H of the patents above named, if the graduating spring and stem were omitted it would be found that after the slide-valve H had been so far shifted in applying the brakes as to permit a moderate or limited quantity of fluid-pressure to pass from the auxiliary reservoir to the brake-cylinder, in such case the amount of power of fluid-pressure necessary to shift such valve part way back, and thus close the port leading to the brake-cylinder, and thereby hold or retain the limited amount or degree of pressure in the brake-cylinder, would frequently give such valve its entire throw and result in the release of the brakes. The important function of graduating would thus be to some extent interfered with, since it is desirable in the handling of a train to be able to admit into the brake-cylinders any desired amount or degree of fluid-pressure less than the maximum, and to retain or hold it there without material increase or diminution. This tendency of the valve referred to, to complete its back stroke under the circumstances named, results, in part, from the fact that the amount of force necessary to start the valve upward when the graduating-spring is not employed is frequently found to be more than enough to carry it to the end of its stroke after it is started. But with the explanation already given,

it will be seen that the necessity of giving a back stroke 1249 & 1250 to the valve H is wholly obviated, so far as relates to closing the ports and holding in the brake-cylinder any predetermined or limited amount of fluid-pressure, or to increase such pressure at pleasure, since, after the slide-valve H has been brought to the desired position, as set forth, a slight motion imparted to the piston G, and much less than would be necessary to start the valve H, will suffice to seat and unseat the auxiliary valve e' , and so hold or retain in the brake-cylinder any desired pressure previously charged therein, or permit the increase thereof at pleasure.

Another part of my invention relates to the use of the auxiliary valve e' as a leakage-valve. When a car is disconnected from the train and run onto a siding, the auxiliary reservoir and brake-pipes are still charged with fluid-pressure. Leakage from the pipes, where it is greatest, results in the depression of the piston G until the port s^2 comes wholly or in part opposite the port C. As the intermediate full face of the valve is insufficient to cover entirely the port C, (the auxiliary valve e' being now unseated,) the fluid-pressure from the auxiliary reservoir will pass out slowly through s^2 , s , and E, but about as fast as it will leak from the brake-pipes. Were it not for this port s^2 , or some other leakage device, the port s^1 would be brought into communication with the port C so as to apply the brakes slowly at first, but eventually with maximum force, and hold them on for a considerable time. This would be highly objectionable, as it would interfere with the shifting of cars and other like operations, or even the running of a car, in case the brake apparatus of such car were disconnected, which it is sometimes necessary to do.

By the same device I provide for unexpected or accidental fluc-

tuations of pressure slight in amount, such as are liable to occur while the pipes are connected and the train running, without danger of the brakes being applied thereto.

In Fig. 4 I have shown a strainer, *m*, arranged over the port leading from B to B¹, as a device to exclude or aid in excluding dust; also, in this figure, the ports from B¹ to B² are shown past the piston G instead of through it.

In both forms of the device I have shown a knob, *q*, projecting from the lower side of the piston G, as a device by which to get hold of the piston and pull it out, when necessary, for purposes of renewal, cleaning, or repairs. The necessity for this results from the fact that heretofore careless workmen have often used the graduating stem for this purpose, and in doing so have bent the stem and caused trouble in the working of the valve.

The function of the large chamber B is chiefly that of a drip-cup, and to discharge the drip a hole and groove are made at *u*.

While in order to make my improvements clearly understood I have described and specified the devices with some minuteness, still include herein known mechanical equivalents, or such substitutes for devices specified as involve a substantially like operation and result.

I claim herein as my invention—

1. In combination with the piston and stem of a triple valve, valve H, arranged on such stem, and having a short range of motion independent of such stem, in combination with an auxiliary valve operated by the same stem to close or open a port through the main valve without necessarily moving the main valve, substantially as set forth.

2. In a valve-case having a fluid-pressure-supply port, an auxiliary reservoir-port, a brake-cylinder port, and exhaust-port, a valve H, for governing the flow of air, provided with ports or passages *s* and *s*¹, and a fluid-pressure-supply port communicating with *s*², in combination with piston G, substantially as set forth with reference to the exhaustion without application of the brakes of the contained fluid-pressure.

3. The valve H, having cavity *s*, ports *s*¹, *s*², *c*, and *c*², in combination with valve *c*¹, substantially as set forth.

4. In combination with a triple valve of the class described, a strainer, *m*, arranged inside the valve-case and over or across the port leading to the piston-chamber, substantially as set forth.

In testimony whereof I have hereunto set my hand.

UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Fluid-pressure Brake.

Specification forming part of Letters Patent No. 235,922, dated December 28, 1880. Application filed November 15, 1880. (No model.)

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Pittsburg, county of Allegheny, State of Pennsylvania, have invented or discovered a new and useful improvement in fluid-pressure-brake apparatus; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, reference being had to the accompanying drawings, making a part of this specification, in which—like letters indicating like parts—

(Here follows diagram marked p. 1252.)

Figure 1 is a sectional view of so much of a brake-cylinder, auxiliary reservoir, and air-regulating valve and connections as is necessary in order to illustrate my present invention. Fig. 2 is a cross-section in the plane of the line *x x*, Fig. 1. Fig. 3 is a section of one-half of Fig. 2 in the plane of the zigzag line *x'* to the center, and an outside elevation of the other half, and Fig. 4 is an enlarged view of the double check-valve of Fig. 1. As the moving parts of the triple-valve device (above termed "air-regulating valve") are well known in the art, I have shown them only in Fig. 1.

My present invention relates to certain improvements in the construction and combination of appliances to be used in and as a part of fluid-pressure-brake apparatus for railway use, and while it is especially adapted for use in what is commonly known as "automatic-brake" apparatus, I also so construct it that it may be used in the non-automatic system of construction and operation—that is, where the fluid-pressure is conducted directly from the source or magazine of power to the brake-cylinder whenever the brakes are to be applied, and on the opening of a cock or valve by the engineer for that purpose. In the automatic system, on the other hand, the fluid-pressure is commonly conducted from the main reservoir or source of power, and stored in auxiliary reservoirs on the several cars, and a valve device, shifted by variations in the air pressure, is arranged in connection with the apparatus in such manner as that, on the accidental or intentional reduction of fluid-pressure in any of the conduit-pipes, a port will be opened from each auxiliary reservoir to a brake-cylinder.

In my present invention I unite in what may be termed a "single structure" the brake-cylinder, the auxiliary reservoir, and the valve apparatus employed for giving proper direction to the flow of the fluid-pressure, and thereby I greatly simplify the construction, make it more compact and at a less cost, and, by dispensing with numerous joints, lessen the liability of loss by leakage, as well as render it

more durable; and by adding in the same combination another of pipe with suitable connections, valve, and ports, I make provision for switching out or cutting off the automatic features, so that a so fitted may be used with other cars having only the usual appliances for non-automatic operation, and all in a more simple manner than any described in my previous patents.

In the drawings, R' represents the auxiliary reservoir, and C' brake-cylinder, made so as to be secured together end to end. A hole in the dividing wall or diaphragm, made for convenience of casting, is closed by a plug, *r*. Holes are also made in the walls of the reservoir R', and a pipe, P', extends from one to the other, through which to convey the fluid-pressure to the brake-cylinder. The outer end of the pipe leads to a valve-chamber and its use will presently be described. The outer end of the reservoir R' has also a large open port, R², and over this port is secured by bolts through bolt-holes A', the valve-case A of what is commonly termed in the Westinghouse-brake system a "triple valve." This device, in consequence of various improvements, has practically ceased to be a triple valve; but as it is commonly known by that term the name may, for convenience, be retained. This device is substantially the construction and operation described in United States patent granted to me October 14, 1879, No. 220,556, and illustrated in Fig. 4 thereof, except that, instead of having a side port and pipe-connection leading to the auxiliary reservoir, the open end of the valve-case is directly opposite to and opens into port R², so that this communication is always open; also, the valve-stem *g*, having no end socket in which to be guided, as in the patent above named, is guided by a winged disk, *r'*, the wings of which play on the walls of the valve-chamber B². The other parts of this triple-valve device, so far as they are like those in the 1254 patent above named, are similarly lettered, and a reference thereto their construction and operation will be readily understood; but instead of the leakage port in that patent (lettered *s*²) in the slide-valve H, I carry a groove (here indicated by the same letter) to the port *s'*; but the operation is not substantially changed thereby. Other devices described in said patent No. 220,556, and not here shown, may be omitted or used, as preferred so far as the same are suitable for use in this construction.

The cap A² of the triple-valve case contains a chamber, B, which opens into the piston-chamber B'. The line of pipe through which fluid-pressure is transmitted for the automatic operation of the apparatus is connected at P. From this point a line of ports leads first, at 1, Fig. 3, into a cock-case, 2, wherein is a plug, 3, having a notch or recess, 4, through which the fluid-pressure passes to a port 5; thence into an annular chamber, 6; thence, by vertical and horizontal ports 7 and 8, into the chamber B. Through this line of ports fluid-pressure is introduced and let off, so as to operate the triple valve, as described in said patent No. 220,556; but for the non-automatic operation of the brakes I connect the fluid-pressure conduit-pipe at P². It will now be seen that this pipe-connection opens into the valve-chamber V on one side, and that the tri-

valve opens into the same chamber on the other side. In order to cut off at pleasure one line or the other of air conduit or communication, I arrange in this chamber a double check-valve, V' , which seats both ways. This double check-valve has a tubular extension, v , which slides like a piston inside the chamber V^2 . From this chamber a side port, g , leads to the escape-port E , or may lead directly to the atmosphere, and when these devices are in the position shown in Fig. 1, (which is the position for the non-automatic action,) a slit or port, u^2 , in the tubular extension v registers with this side port through port u in the bush or lining of the chamber. Other ports, u' , are also made in this tubular extension, for purposes presently to be explained. A pin, x , on which the tubular extension plays, by a slit, x' prevents the rotation of the extension. The opposite or outer end of the double-check-valve stem has a cylindrical part, v^2 , which, when the valve is shifted outwardly, fills the adjacent end of the bore of the chamber V^3 as soon as the opposite or automatic port is opened, and outside of this is a winged stem, v^3 .

Assuming now that the non-automatic system of operation is to be used, fluid-pressure, entering at the port P^2 , shifts the double check-valve V' over to the position shown, so as to cut off the automatic feature from the line of communication. The fluid-pressure then passes, as indicated by the arrows, Fig. 4, into and along the pipe P' , to the brake-cylinder C' , and there does its work in the usual way. If, then, at the same time, either accidentally, by design, or in consequence of leakage, any comparatively small amount of fluid-pressure should come through the triple-valve ports into the tubular extension v , it will at once pass out by the ports g and E ; but if it be desired to employ the automatic system of operation, the reservoir R' is charged, (if not already charged,) and on the reduction of the pressure in the brake-pipe the triple valve is shifted, so as to let the pressure pass from R' through the port R^2 , shift the piston G and valve H , so as to uncover the port C , and thence through this latter port into the tubular extension v . As the port u is too small to provide for its escape, it acts to throw the double check-valve V' outward and close the non-automatic port. This brings the holes u' and slit u^2 , made in the walls of the tubular extension v , outside the valve-seat at that end of the chamber, or, in other words, causes them to open into the valve-chamber V ; and it will be observed that this end of the valve-stem has a cylindrical port, v^4 , so that the ports u' u^2 are not uncovered until the cylindrical part v^2 on the other end of the valve shall have practically closed the non-automatic port. The fluid-pressure thus introduced passes by the pipe P' to the brake-cylinder, and also does its work in the usual way. The brakes may be released in the manner described in said patent No. 220,556.

The apparatus thus described I propose to use either as automatic or as non-automatic, with a single line of pipe; or, what is still better, I propose to use two lines of pipe, and use either method of operation at pleasure, or sometimes one and sometimes the other. For holding a long passenger or freight train in check on a long

downgrade, the non-automatic method of working is in some respects preferable, whereas for stopping purposes, particularly in an emergency, the automatic is much the better. Hence on roads in hilly or mountainous regions it is well to have both methods available, at the pleasure of the engineer, and in such use the automatic apparatus should always be kept charged and in a usable condition, so that it may be used or made available for an emergency stop, or in case of accident, as well as for ordinary stops, even while the non-automatic apparatus may be employed at intervals for certain purposes; but in case it should become necessary, as it sometimes does, to exhaust or discharge the compressed fluid-pressure from the brake-cylinder R' , it may be done by the turning of the plug 3 (a handle, 10, being added for the purpose) so as to bring the port 12 into line with the ports 13 and 14, Fig. 2, the former of which is in communication with the valve-chamber V , and the latter of which opens to the outer air. This necessity may arise when a car is detached from the train, and by the escape of air from the brake-pipe the brakes are set and remain so.

It is also an important and novel characteristic or feature of my present apparatus that I provide for the discharge of the 1255 & 1256 fluid-pressure from all the auxiliary reservoirs of the train by the use of a higher or a mechanically more effective pressure through the non-automatic pipe. Thus, in case of the bursting or breakage of any of the fluid-pressure conduits of the automatic apparatus, (which may occur while the train is at a place or point on the line where repairs are almost practically impossible,) the pipe-valves throughout the train are shifted, and fluid-pressure then passes from each auxiliary reservoir to its brake-cylinder, and all the brakes are set. Of course they can be released in the manner already described; but I deem it better in such cases to discharge the fluid-pressure from the auxiliary reservoirs, so that the brakes cannot in any contingency again be reset by a new charge from such reservoirs. To this end I pump up, if need be, and transmit back through the non-automatic pipe, a pressure sufficient to shift each valve V' , as against the pressure to which it may be subject from its auxiliary reservoir, so as to cause the port or slit u^2 to register with the port u , and thereby allow all the pressure in all the auxiliary reservoirs to escape through ports 9 and E to the open air. This being done, the brakes may be released in the manner common in the working of the non-automatic brake, and the train may proceed, using then the latter apparatus for braking purposes until damages are repaired; but in the operation thus described the plug 3 is presumed to be absent, or, if present, to be closed as regards the ports 13 and 14.

The plug 3 may be used to cut off the automatic apparatus entirely, when desired, by setting it so as to cut off all the ports leading into or through the same.

In order to guard against the effects of the leakage of fluid-pressure into the brake-cylinder, (when it occurs,) I make a small groove, z , in the interior of the cylinder, past the piston C^2 when it is at the end of its back-stroke, or when the brakes are off; and I make this

groove large enough to provide for the escape of so much fluid under pressure as is liable to leak into the cylinder, but so small that it cannot carry off an operative charge or quantity. As soon as the piston on its forward or outward stroke laps onto the outer end of the groove, the latter ceases to perform any function whatever.

In lieu of the specific form or construction of triple valve described, any other known form of device for regulating and governing the flow of fluid-pressure in a substantially like manner by the action of the fluid-pressure itself may be substituted without any substantial departure from the scope of the present invention, and such substitutes, performing a like function, I include within the term "triple valve," as hereinafter used; and, particularly, it may be stated that for some uses the triple valve may be arranged on one side of the reservoir R', instead of at its end, both arrangements thereof being included herein, and like variation may be made in the arrangement of the brake-cylinder.

I claim herein as my invention—

1. In a fluid-pressure-brake apparatus, a triple valve, auxiliary reservoir, and brake-cylinder arranged end to end in a single structure, without interposed pipes to connect one to the next, substantially as set forth.

2. The combination of a brake-cylinder furnished with a piston moving therein, arranged on one end or side of a reservoir, a triple valve arranged on another end or side, and a pipe connecting the triple valve with the brake-cylinder, substantially as set forth.

3. A valve-chamber, V, containing a double check-valve, in combination, by port C and pipe P', with triple valve, auxiliary reservoir, and brake-cylinder, substantially as set forth.

4. A double check-valve, V', having a ported tubular extension, v , thereon, in combination, by ports C, E, and G, with triple valve, substantially as set forth.

5. The double check-valve V', having cylindrical extensions v^1 and v^2 and ported tubular extension v , as a device for cutting off one of two different sets of fluid-pressure-brake apparatus while bringing the other into communication, substantially as set forth.

6. The cock and case having line of ports and passages 1, 4, 5, 6, 7, and 8, substantially as set forth.

7. The cock 3, in combination, by ports 12, 13, and 14, with chamber V and passages thence to auxiliary reservoir and brake-cylinder, substantially as set forth.

8. In a fluid-pressure-brake apparatus having automatic and non-automatic appliances and a pipe-connection for each, the method of discharging the fluid-pressure from the auxiliary reservoirs of the train, by charging through the non-automatic connection a pressure sufficient to shift a valve and open an escape-port communicating with each such reservoir, substantially as set forth.

In testimony whereof I have hereunto set my hand.

GEORGE WESTINGHOUSE, JR.

Witnesses:

R. H. WHITTLESEY.

GEORGE H. CHRISTY.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Air-brake Apparatus.

Specification forming part of Letters Patent No. 243,415, dated June 28, 1881. Application filed April 1, 1881. (No model.)

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., of Pittsburg, county of Allegheny, State of Pennsylvania, have invented or discovered a new and useful improvement in air-brake apparatus; and I do hereby declare the following to be a full, clear, concise, and exact description thereof, reference being had to the accompanying drawings, making a part of this specification, in which—like letters indicating like parts—

(Here follow diagrams marked pp. 1258 & 1260.)

Figure 1, sheet 1, is a longitudinal sectional view of the "triple" or automatic valve employed in my present improvement, with its ports and connections, and also showing, in part, an auxiliary reservoir and valve-chamber. Fig. 2 is a transverse sectional view in the plane of the line *xx* of Fig. 1, looking to the left, and showing the cock, plug, or key K in elevation. Fig. 3 is a side elevation of the triple-valve case as looked at from the left of Fig. 2; and Fig. 4, sheet 2, is a diagram view illustrative of the organization of a brake apparatus embodying the present improvements.

My present invention is more particularly directed to the construction and combination of apparatus whereby the two styles or systems of air-brake apparatus commonly known as the "Westinghouse compressed-air brake" and the "Westinghouse automatic brake" may be combined in use and operation at the same time on the same train.

While I do not limit myself to any particular train use of this combination, I have devised it with particular reference to train purposes, especially on roads which have long and heavy grades, and where a moderate but comparatively constant degree or amount of brake-power has to be applied for a considerable time; and I also provide an improved means for releasing and cutting off or out of action the automatic part of the apparatus in case, for any reason, it should get out of order when out on the line where repairs can not be made.

Some of the features of construction of the present apparatus are shown in patent No. 235,922, granted to me December 28, 1880. Here, as there, the brake-cylinder, the auxiliary reservoir, and the valve-case which contains the valve apparatus employed for giving proper direction to the flow of the fluid-pressure in the automatic brake, are, by preference, included in what may be termed a "single

structure," one of such structures being applied to each car as a part of the automatic appliances.

In the diagram, Fig. 4, I have shown in outline, but with sufficient clearness for the present purpose, an air-compressing pump, P^{10} , a main reservoir, R^{10} , the air inlet-pipe p , which supplies air to the pumping-cylinder, and the air-pipe p' , which leads to the main reservoir. From this main reservoir, usually arranged on the locomotive, two lines of brake-pipe extend back beneath the cars of the train. The one line, q , leads, by the ordinary three-way cock q' , to the brake-pipe q^5 , which pipe and cock may represent such as are used with the "Westinghouse compressed-air brake," so called, wherein the power is first stored up in the reservoir, and then by manipulation of the cock is allowed to flow back through the brake-pipes when, and only when, it is desired to apply the brakes. In the other line a pipe, q^2 , leads to a cock, q^3 , such as is used or is adapted for use in working the Westinghouse automatic brake, and from this the brake-pipe q^6 leads back beneath the cars, as before. This line may be called the "automatic line." The usual hose and couplings are to be added between cars, and in other respects (not herein specified) these appliances are to be fitted up in any of the ways known in the art.

The apparatus through which both lines of pipe, q^5 and q^6 , are brought into conjoint use is illustrated in all the figures, but more fully in Fig. 1, where R^9 represents the auxiliary reservoir, and C^9 the brake-cylinder, a portion of each being broken away for convenience of illustration. The outer end of the reservoir R^9 has a large open port, R^8 , and over this port is secured, by bolting or otherwise, the valve-case A of what is termed in the Westinghouse automatic brake a "triple valve." This triple-valve device has substantially the construction described in United States patent No. 220,556, granted to me October 14, 1879, with more particular reference to Fig. 4 thereof, with the exception that the port there marked C , and here marked $C C'$, leads by pipe P^8 directly through the auxiliary reservoir R^9 to the brake-cylinder, here marked C^9 , though obviously it may pass around outside the auxiliary reservoir,

1262 if so preferred; also, the escape-port there, as here, lettered E , instead of opening into the open air, opens into a branch, q^7 , Fig. 4, of the line of brake-pipe q^5 ; also, the cock K , in addition to the ports $k k'$, has an additional port, z , which opens to the external atmosphere, Figs. 2 and 3.

The construction and operation of devices not herein specifically described will be readily understood by reference to the patent last named, where similar devices have like lettering; but even this reference is unnecessary, as the devices in question are already in extensive public use, and, as such, constitute a part of the art already known to those skilled therein.

With the appliances in their usual or normal condition—that is, with the pipe q^5 free of more than atmospheric pressure, the cock q' closed, the cock q^3 open, so that the pipe q^6 , with its branch q^7 , and the auxiliary reservoirs R^9 charged with a working fluid-pressure, and the triple valve in the position shown in Fig. 1, the train will

be in running order and the brakes will be off. Each auxiliary reservoir will receive its charge of compressed air from q^8 by the appropriate ports and passages P, k, P', B, b, B', a a' a², B² and R². If, now, the engineer wishes to apply the brakes, he shifts his automatic cock q^3 in the usual way, which will result in the lowering of the pressure in the brake-pipe q^6 and chamber B', cause a back-stroke of the piston G, which will shift the valve H, cut off the port E, and open communication from R², through C, k', and C' and P² to the brake-cylinder C², so as to apply the brakes with more or less force, according to the amount of the reduction of air-pressure in the pipe q^6 .

Thus far the operation varies in no material respect from what is described in the patents above referred to; but it is of great importance in the running of heavy trains down very long and steep gradients that a uniform and easily regulated variable pressure be maintained in the brake-pipes and cylinders, which is sometimes somewhat difficult with the automatic apparatus alone.

By my present invention, instead of exhausting into the open air the fluid-pressure as it escapes from the brake-cylinder when the brakes are partially or wholly released by the "automatic" method of operation, I connect the escape-port E, by the branch q^7 , with the pipe q^5 , so that the escaping air shall go into and be confined in such pipe. Then, as the brakes are successively applied and released in the automatic operation, the fluid-pressure escaping from the brake-cylinder on each release will be charged into the brake-pipe q^5 , and will soon accumulate to, or nearly to, the degree of pressure which the engineer may desire to preserve in his brake-cylinder, and the pipe q^5 and the brake-cylinder being brought into communication on each release, the same degree of pressure, or nearly the same, will soon exist in both. In case such degree of pressure should accidentally or by miscalculation, or in consequence of a change in the speed of the train, or on account of a change of grade, or for other cause, become too great, such operative pressure may be reduced much or little by shifting the cock q' so as to lower the pressure in q^5 , and, of course, in the brake-cylinder.

Should operative pressure at any time, for any reason, be too little, it may be increased by working the automatic, as before, or by shifting the cock q' so as to turn on pressure from the main reservoir through the pipe q^5 . In this way, through two separate lines of connection, each of which may be brought into action independently of the other, the engineer possesses the most perfect control over his brakes, and through them over his train, on all variations of track, grade, or speed; and it is also a further advantage that while the automatic acts the more quickly, it is possible, by combining the two systems of operation, particularly with engineers unskilled in the accurate use of the automatic, to get more accurate adjustments of brake-power by using the compressed-air system by pipe q^5 , for effecting slight variations of pressure after the average or approximately the desired pressure has been attained with the automatic. Also, it has sometimes happened in unskilled hands or in consequence of injury or imperfect care, that the automatic

brake would not release on the restoration of the pressure in pipe g^6 . When this happens the cock K may be turned so as to bring the port z into communication with the port C', and thereby let the air escape from the brake-cylinder C⁹, and so release the brakes. To this end the port z is made lengthwise of the cock, key, or plug, and at its outer end opens to the atmosphere.

I have described the invention as applied to a single set of car equipment; but the apparatus described is merely duplicated on the different cars of the train. It should be stated, however, that the hose-couplings between the cars on the pipe g^5 , by preference, have no valves to close their ports when a train pulls in two, and the rear coupling of the last car should be closed by a dummy, special cock, or otherwise.

I claim herein as my invention—

1. The method of combining a compressed-air system of brake apparatus and an automatic system by connecting the brake-pipe of the former with the exhaust-port of the latter, substantially as set forth.

2. A cock, K, having an exhaust-port, z, in combination with the brake-cylinder and exhaust-pipe of an automatic brake apparatus, substantially as set forth.

In testimony whereof I have hereunto set my hand.

UNITED STATES PATENT OFFICE.

GEORGE A. BOYDEN, of Baltimore, Maryland, assignor of one-half to Charles B. Mann, of same place.

Fluid-pressure Brake.

Specification forming part of Letters Patent No. 280,285, dated June 26, 1883. Application filed April 30, 1883. (No model.)

To all whom it may concern :

Be it known that I, George A. Boyden, a citizen of the United States, residing at Baltimore, State of Maryland, have invented certain new and useful improvements in fluid-pressure brakes, of which the following is a specification, reference being had therein to the accompanying drawings.

My invention relates to certain improvements in fluid-pressure brakes for railway-trains, and to an improved method of applying and maintaining the application of the brakes.

The objects of the invention are, first, to provide for replenishing while the brake is on, the air-reservoir on each car or the brake-cylinder when the pressure therein has been lessened by leakage, and to accomplish this through a single line of train-pipe and by means which shall at all times be wholly under the control of the engineer, and also to provide for the more rapid charging than heretofore of the air-reservoir on the car, and also to obviate the necessity of applying the brakes with such a high pressure as heretofore has been necessary with the automatic brake, the effect of which is to slide the wheels and flatten them; second, to provide for dispensing with the main air-reservoir on or near the locomotive, and thereby simplify and cheapen the apparatus; third, to provide for the quicker release of the brake.

My invention consists, first, in the several combinations, herein-after specified, with an air-reservoir on the car, of means whereby the said air-reservoir may be replenished or recharged with compressed air while the passages or ports leading therefrom to the brake-cylinder are open and while the brakes are applied; second, in the combination, with an air-reservoir on the car and air-compressing apparatus on the locomotive, of means whereby is afforded the principal advantages of the "automatic" brake system, as well as the direct compressed-air system, without employing the usual main air-reservoir on or near the locomotive; third, in the combination, with an air-reservoir on the car, of a brake-releasing valve, whereby, when the train-pipe contains the maximum fluid-pressure, the brakes will be released quickly; fourth, in a new method of applying and maintaining the application of the brakes through a single line of train-pipe, as hereinafter specified.

Figure 1 is a view of the parts properly assembled of a brake apparatus embodying my invention. Fig. 2 is a sectional view, showing one plan of constructing the valve mechanism and air-cushion chamber. Fig. 3 is a sectional view, showing another plan of constructing the same parts.

The letter A designates the case of the valve; B, the drip-chamber attached at the bottom, (see Fig. 2,) and A' packing interposed between these parts, which are united by bolts A². (See Fig. 1.)

At the port P the train-pipe P² is attached. From this port a passage, P', leads to the drip-chamber B. Adjoining this chamber is a cylinder, B', fitted with a piston, G, which connects with a slide-valve, H, by means of a stem or rod, g. Instead of a slide-valve an ordinary three-way cock may be used. The slide-valve H has a cavity, s, long enough to uncover the passage C' and the exhaust-port E and put them in communication. The passage C' has outlet at port C, from which the pipe C² connects with the brake-cylinder C³.

At the port R is connected the pipe R², which leads to the air-reservoir R³ on the car. R' is a passage direct from this port to the valve-chamber.

A four-way cock, K, with ports k k', is arranged in line of the fluid-pressure communication, to provide for operating the brakes of the car by either the automatic system or the direct compressed-air system, according as the train of which the car forms part may happen to be fitted out.

The construction of the parts thus far described may vary or be changed in many ways without materially affecting the operation or result of my improvements, which I will now proceed to describe.

Extending from the drip-chamber is a passage, D, provided with a check-valve, d, adapted at all times to allow compressed air from the train-pipe P² to reach the air-reservoir on the car, but preventing its return therefrom, whereby no loss of fluid-pressure 1270 from reservoir R³ can occur in case of accidental separation of the car from the train, and serving also, as hereinafter explained, to allow compressed air from the train-pipe to reach the brake cylinder C³ while the brake is applied. As the fluid-pressure can take but one direction in this passage, I call it "an always-open one-way passage." A passage substantially like this, always open for fluid-pressure to reach the air-reservoir on the car, constitutes one feature of my invention.

The check-valve d may be constructed in any suitable manner. In the present case it has crossed wings d', which fit in the passage and adapt it to slide like a piston, so that the valve may leave its seat. In Fig. 2 a shank or rod, d², projects from the valve, and has attached a head, d³, which fits in a cylinder or bore, d⁴. A spiral-spring, d⁵, bears on the head in such manner as to keep the check-valve normally to its seat. At the other end of the piston stem or rod g, and connected thereto, is a second piston, I, fitting and arranged to move in a cylinder provided with a port, j, adapted to be closed when the piston is in one position and to be opened when the piston is in another. This port connects with an air-cushion

chamber, L. This air-cushion, or its equivalent, constitutes a feature of my invention. The air-cushion chamber L may be constructed without any opening, port, or valve whatever other than the one *j*, which is opened and closed by the piston I. This air-cushion chamber is employed to receive compressed air transmitted through the train-pipe at the maximum pressure. When the brakes are off, the piston I is in the position shown, and the fluid-pressure in the air-cushion chamber, which is on the outer side of the piston, is the same as the pressure on the inner side of the piston; but when the fluid-pressure in the train-pipe P^2 is reduced, such reduction of course is felt on the inner side of the piston, and thereupon the maximum pressure existing in the air-cushion chamber presses the piston I back, and through the stem *g* shifts the slide-valve H, closing the exhaust-port E and opening direct communication between the air-passage R' and the brake-cylinder passage C', thereby applying the brakes. It will thus be seen the first effect produced by the fluid-pressure in the air-cushion chamber is to shift the valve H, which applies the brakes. Heretofore in the Westinghouse brake the shifting of the valve has been effected wholly by the back action of the fluid-pressure in the auxiliary air-reservoir. Now, after a lessening of the fluid-pressure in the reservoir on the car or brake-cylinder, by leakage, has occurred, the maximum pressure in the chamber L has the further effect to act as an air-cushion to hold the valve H in the same position while the engineer manipulates the cock *g* on the locomotive to allow compressed air from the compressing apparatus to be transmitted through the always-open one-way-only passage D under a less pressure than the maximum, or less than that in the chamber L, to recharge and to continue charging the reservoir and brake-cylinder while the brakes are applied. This is a new and an important achievement through a single line of train-pipe, and enables me to dispense with the customary main air-reservoir on or near the locomotive, and constitutes a new method of maintaining the application of the brakes after they have been applied, and is a feature of my present invention. As long as the recharging is continued with the fluid under a less pressure than the maximum, or less than that in the chamber L, there will be no relaxation of the grip of the brake-shoes on the wheels.

Instead of a piston, I, for the fluid-pressure in the air-cushion chamber L to press against, a flexible or elastic diaphragm with suitable valves might be substituted. So far as concerns the air-cushion, of which the piston I is a part or necessary adjunct, I include as within my invention all known equivalents for the piston which will operate substantially as herein set forth.

It has been stated that the air-cushion chamber may be constructed without other opening, port, or valve than that which is opened and closed by the piston I; but in the present instance a valve, N, is provided in the said chamber, and its use effects the quick release of the brake, and the same constitutes another feature of my invention. This brake-releasing valve consists, as shown in Fig. 2, of the escape-port *f*, a right-angled lever, P, one arm of which

carries the valve N, which closes the escape-port, and the other arm of which carries a pivoted trigger, r . This arm is adapted to move laterally. When pressed down at one side, the trigger will yield, but when pressed upward on the same side it is unyielding. A spring, s , is arranged to keep the trigger normally in a given position. The piston-stem g has its upper end, g' , projecting past the piston I and into the air-cushion chamber. A head, g^2 , is on the projecting end.

From this description of the drawing it will now be understood that when on applying the brakes the piston I is pressed back by the maximum fluid-pressure in the chamber L the trigger r will yield as the head g^2 on the stem passes down, thereby allowing the head to pass. When the maximum fluid-pressure is transmitted from the compressing apparatus on the locomotive to release the brakes, the pistons and stems are forced up; but their upward movement now would ordinarily be tardy, because of the resistance of the air-cushion, and hence the brake now would be released slowly. This tardy release of the brake is a difficulty also sometimes experienced in the Westinghouse automatic brake on account of the resistance of the air in the auxiliary reservoir. To remedy this therefore, when the stem starts on its upward movement the head g^2 at

once comes in contact with the trigger r , which, not yielding, 1271 causes one arm P of the lever to move laterally, thereby removing the valve N from its seat over the escape-port and instantly allowing the fluid-pressure in the chamber to exhaust. There being then no longer any resistance, the brakes will be released instantly.

To charge the brake apparatus with fluid-pressure, compressed air from the compressing apparatus is transmitted through the train-pipe, and then direct through the always-open one-way passage to the air-reservoir. In charging as here described the circuitous and smaller passages or ports of the Westinghouse triple valve heretofore used are avoided. The fluid-pressure thus transmitted from the compressing apparatus, coming against the pistons G and I, forces them up, thereby closing the brake-cylinder passage C' and opening the port j , which allows the maximum fluid-pressure to enter the air-cushion chamber L. The same pressure at the outset will therefore exist on both sides of the piston I. Now, to apply the brakes, the engineer by slightly opening the cock q reduces the pressure in the train-pipe below the maximum stored in the air-cushion chamber, whereupon the effect is to press the pistons I G down, thus allowing the fluid-pressure in the reservoir R³ to pass through passages R' and C' into the brake-cylinder and apply the brakes. When through a lessening of the fluid-pressure by leakage it is desired to replenish or recharge the brake-cylinder without either releasing the brakes or relaxing the grip of the shoes on the wheels, the engineer may manipulate the cock q to transmit air under a less pressure than that stored up in the air-cushion chamber. By this method a constant supply of fluid-pressure is maintained in the air-reservoir on the car, and there is no longer need for a main air-reservoir on the locomotive, as heretofore.

In Fig. 3 the always-open one-way passage D and check-valve *d* is shown through the piston G instead of entirely at one side, as in Fig. 2. The case A, drip-chamber B, and air-cushion chamber L are here shown united in a single casting instead of being composed of three pieces, as in Fig. 2. A cap, A³, is bolted over and constitutes the top of the air-cushion chamber. As shown in this figure, the device can be more cheaply constructed.

As already explained, the form, and to some extent the arrangement of the valves, ports, and passages, may be varied or changed without materially affecting the operation of the parts herein combined, and I hereby include such modifications as within the scope of my invention. I also include herein as an equivalent for the air-cushion chamber any substitute—such as a spring—which may be compressed by the maximum fluid-pressure, and then, when such pressure is reduced to apply the brake, will, like the air-cushion, hold the valve H while the brake-cylinder is replenished or recharged. Any such equivalent or substitute as produces substantially a like operation or result I here include as of my invention.

While the several novel features—to wit, air-cushion chamber L, the release-valve N, and the always-open one-way-only passage D—are adapted and specially designed for use without reference to and independent of a main air-reservoir on the locomotive, and are so shown here, said features may nevertheless be used, with all their resulting advantages unimpaired, in connection with a main air-storage reservoir on the locomotive, as now employed by the Westinghouse system of automatic brakes. Therefore my claims herein-after given apply and cover said features in both said systems. In the event of the accidental separation of the cars of a train, the brakes will at once be applied as in the automatic brake-system.

By my improvements very important results are attained—to wit, a brake is provided which affords the principal advantages of the automatic system, as well as the principal advantages of the "direct" compressed-air system, without the disadvantages or difficulties heretofore experienced in either.

Having described my invention, I claim and desire to secure by letters patent of the United States—

1. In fluid-pressure brakes, the combination, with the train-pipe and an air-reservoir on the car, of a passage between the two always open one way only adapted at all times to allow fluid-pressure to enter the air-reservoir, substantially as set forth.

2. In fluid-pressure brakes, the combination, with a brake-cylinder, an air-reservoir on the car, and valve mechanism to open and close connection between the cylinder and reservoir, of means, substantially as described, whereby the brake-cylinder may be directly recharged with fluid-pressure from a single line of train-pipe while the brakes are applied, as set forth.

3. In fluid-pressure brakes, the combination, with a brake-cylinder, an air-reservoir on the car, and valve mechanism to open and close connection between these two, of an air-cushion chamber provided with means by which air compressed in the chamber will hold the

valve mechanism to maintain communication between the reservoir and cylinder, substantially as set forth.

4. In a fluid-pressure brake, the combination of a brake-cylinder, an air-reservoir on the car, valve mechanism to open and close connection between the cylinder and reservoir, means, substantially as described, to hold the valve mechanism, air compressing apparatus on the locomotive, and train-pipe to connect directly between the air-compressing apparatus and the said appliances on the car, whereby the usual main air-reservoir on or near the locomotive is dispensed with, as set forth.

5. In a fluid-pressure brake, the combination of a brake-cylinder, an air-reservoir on the car, valve mechanism to open and close connection between the cylinder and reservoir, means, substantially as described, to hold the valve mechanism and a passage
1272 always open one way only to allow fluid pressure from the train-pipe to enter the brake-cylinder while the brakes are applied, as set forth.

6. In fluid-pressure brakes, the combination, with the valve mechanism which opens and closes communication between the brake-cylinder and air-reservoir, of a brake-releasing valve adapted, when fluid-pressure is applied in the train-pipe, to release the pressure back of the valve mechanism, substantially as set forth.

7. In fluid-pressure brakes, the method of applying and maintaining the application of the brakes through a single line of train-pipe, consisting of first applying the brakes by the admission to the brake-cylinder of the fluid-pressure in the air-reservoir on the car, and then maintaining the application of the brakes by the admission to the brake-cylinder of fluid-pressure directly from the air-compressing apparatus on the locomotive, as set forth.

8. In fluid-pressure brakes, the method of applying and maintaining the application of the brakes through a single line of train-pipe, consisting of compressing air and transmitting the maximum pressure to the air-reservoir on the car, applying the brakes from the air-reservoir by reducing the pressure in the train-pipe, and then, when through a lessening of the pressure by leakage it is desired to recharge, transmitting through the train-pipe compressed air under a less pressure than the maximum, as set forth.

In testimony whereof I affix my signature in presence of two witnesses.

1279

UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Fluid pressure Automatic-brake Mechanism.

Specification forming part of Letters Patent No. 360,970, dated March 29, 1887.

Application filed November 19, 1886. Serial No. 219,353. (Model.)

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., residing at Pittsburg, in the county of Allegheny and State of Pennsylvania, a citizen of the United States, have invented or discovered certain new and useful improvements in fluid-pressure automatic-brake mechanism, of which improvements the following is a specification.

The object of my invention is to enable the application of brake-shoes to car-wheels by fluid pressure to be effected with greater rapidity and effectiveness than heretofore, more particularly in trains of considerable length, as well as to economize compressed air in the operation of braking by utilizing in the brake-cylinders the greater portion of the volume of air which in former practice was directly discharged into the atmosphere.

To this end my invention, generally stated, consists in a novel combination of a brake-pipe, an auxiliary reservoir, a brake-cylinder, and a "triple-valve" device governing, primarily, communication between the auxiliary reservoir and the brake-cylinder, and, secondarily, communication directly from the brake-pipe to the brake-cylinder.

The improvements claimed are hereinafter fully set forth.

In the application of the Westinghouse automatic brake as heretofore and at present commonly in use, each car is provided with a main air-pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve, the triple valve having three connections—to wit, one to the main air-brake pipe, one to the auxiliary reservoir, and one to the brake-cylinder. The main air-pipe has a stop-cock at or near each of its ends, to be opened or closed as required, and is fitted with flexible connections and couplings for connecting the pipes from car to car of a train, so as to form a continuous line for the transmission of compressed air from a main reservoir supplied by an air-pump on the engine. When the brakes are off or released, but in readiness for action upon the wheels of the train, the air which fills the main reservoir and main air-pipes has a pressure of from sixty-five to seventy-five pounds to the square inch, and by reason of the connections referred to the same pressure is exerted in the casings of the triple valves on both sides of their pistons and in the auxiliary reservoirs connected therewith. At the same time passages called "release-ports" are open from the brake-cylinders to the atmosphere. When it is desired to apply the brakes, air is allowed to escape from

the main air-pipes through the engineer's valve, thereby reducing the pressure in the main air-pipes, whereupon the then higher pressure in the auxiliary reservoirs moves the pistons of the triple valves, so as to first close the passages from the triple valves to the brake-pipe and at the same time close the release-ports of all the brake-cylinders, and then open the passages from the auxiliary reservoirs to the brake-cylinders, the pistons of which are forced out by the compressed air thereby admitted to the brake-cylinders, applying the brakes by means of suitable levers and connections, all of which mechanism is fully shown in various letters patent granted to me.

The application of the brakes with their full force has heretofore required a discharge of air from the main pipe sufficient to reduce the pressure in said pipe below that remaining in the auxiliary reservoir after the brakes have been fully applied, and it has been found that, while the brakes are sufficiently quick in action on comparatively short trains, their action on long trains of from thirty to fifty cars, which are common in freight service under present practice, is in a measure slow, particularly by reason of the fact that all the air required to be discharged from the main pipe to set the brakes must travel from the rear of the train to a single discharge-opening on the engine. This discharge of air at the engine has not only involved a serious loss of time in braking, but also a waste of air. Under my present invention a quicker and more efficient action of the brakes is obtained, and air which has been heretofore wasted in the application of the brakes is almost wholly utilized to act upon the brake-pistons.

In the accompanying drawings—

(Here follow diagrams marked pp. 1274, 1276, & 1278.)

Figure 1 is an inverted plan view of a railroad-car, illustrating the application of my invention; Fig. 2, a longitudinal section, on an enlarged scale, through the triple valve at the line *xx* of Fig. 4; Fig. 3, a transverse section through the same at the line *yy* of Fig.

2; Fig. 4, a bottom plan view of the cap or drain-cup of the triple valve; Fig. 5, a longitudinal section through the triple valve at the lines *zz* of Fig. 3 and *ww* of Fig. 6; Fig. 6, a partial bottom plan view of the triple valve; and Fig. 7, a longitudinal central section through the brake-cylinder and auxiliary reservoir, with the triple valve in elevation.

In the practice of my invention each railroad car 1 on which it is applied is, as heretofore, provided with a main air-pipe, 2, governed by stop-cocks 3, adjacent to its ends, and having a flexible connection, 4, and coupling 5 at each end, to admit of being coupled to the main air-pipe of the tender or the adjacent car or cars of a train. An auxiliary reservoir, 6, and brake-cylinder 7 are secured in convenient position below the sills of the car, the brake-cylinder having a piston, 52, by the movement of which, through a system of lever-connections, which do not form part of my present invention, the brake-shoes 9 are applied to and released from the wheels of the car, compressed air being supplied to and released from the brake-

cylinder 7 as the pressure in the main air-pipe is reduced or reinstated, respectively, by means of a triple valve, 10, the casing or chest of which communicates with the main air-pipe, the auxiliary reservoir, and the brake-cylinder.

So far as the performance of its preliminary function in ordinary braking is concerned—that is to say, effecting the closure of communication between the main air-pipe and the auxiliary reservoir, and the opening of communication between the auxiliary reservoir and the brake-cylinder in applying the brakes, and the reverse operations in releasing the brakes—the triple valve 10 accords substantially with that set forth in letters patent of the United States No. 220,556, granted and issued to me October 14, 1879, and is not, therefore, saving as to the structural features by which it performs the further function of effecting the direct admission of air from the main air-pipe to the brake-cylinder, as presently to be described, claimed as of my present invention. Certain of its elements devised and employed by me prior thereto will, however, be herein specified, in order to render its construction and operative relation to other members of the brake mechanism fully intelligible.

The case or chest in which the operative mechanism of the triple valve proper, 10, is mounted is fixed under or on the car-body in any convenient position relatively to the auxiliary reservoir 6 and brake-cylinder 7, being in this instance shown as secured directly to one end of the auxiliary reservoir, in line axially therewith and with the brake-cylinder, which is secured to its opposite end. The triple-valve case is fitted at one end with a cylindrical sleeve or bushing, 11, which is bored out truly and forms the chamber of a piston, 12, which is fixed upon a stem, 13, carrying, as in my letters patent No. 220,556, before mentioned, a slide-valve, 14, which controls communication between the auxiliary reservoir and the brake-cylinder, and between the brake-cylinder and release-port 15, respectively. The auxiliary reservoir 6 is continuously in communication with the chamber 11, on one side of the piston 12, through the longitudinal chamber 24 of the case in which the slide-valve 14 moves, and the triple-valve case communicates, by a passage, 16, with the brake-cylinder, and, by a passage, 17, with the main air-pipe 2. The passage 17, leading from the main air-pipe, communicates, by a passage, 18, with the cap or, as it is ordinarily termed, the "drain-cup" 19 of the triple valve, from which passages 20 lead into the piston-chamber 11. A four-way cock, 21, controls the passages 16, 17, 18, and a passage, 22, leading to a port, 23, in the face or seat of the slide-valve 14. When in the position shown in the drawings, communication is continuously maintained between the main air-pipe 2 and piston-chamber 11, through the passages 17 and 18, drain-cup 19, and passages 20, and by turning the cock 21, so as to establish communication between the passages 16 and 17, the triple valve and auxiliary reservoir will be cut out from the main air-pipe, and the mechanism can be operated as a non-automatic brake, the admission of air under pressure to the main air-pipe and brake-cylinder effecting, in such case, the application of the brakes.

The entire brake mechanism of the car other than the main air-pipe may be put out of action, when for any reason required, by turning the cock 21 into position to cover the passages 16 and 18, the main air-pipe then serving only for the transmission of air between the portions of the train-line made up by the main air-pipes of the remaining vehicles.

The slide-valve 14 is loosely connected with the stem 13 of the piston 12, and by a pin, 25, extending across the stem and fixed in the side plates of the valve, is prevented from being separated from the stem when removed for examination. It is held up to its seat in the chamber 24 by a spring, 26. The valve partakes in the reciprocating movements of the stem 13, being moved in one or the other direction by a collar, 27, and a shoulder, 28, respectively, on the stem. Said collar and shoulder are located at a distance apart slightly greater than the length of the valve 14, so that a limited degree of traverse of the stem 13 and piston 12 in each direction is effected without imparting movement to the valve. A graduating-valve, 29, secured upon a stem, 30, which is moved by the piston-stem, 13, governs a passage, 31, in the slide-valve 14, said passage communicating by a lateral port, 32, with the valve-chamber 24, and consequently with the auxiliary reservoir. A cavity or passage, 33, is formed on the face of the slide-valve 14, of such length as to establish communication during a portion of the traverse of 1281 the valve between the port 23 of the valve-chamber 24, which is open to the passage 16, leading to the brake-cylinder, and a port, 34, communicating with the relief-port 15.

The construction and relative arrangement of the piston-stem 13, slide-valve 14, and graduating-valve 29 are substantially similar to those of the corresponding parts as heretofore employed by me and exemplified in my letters patent No. 220,556; but under my present invention these are supplemented by a port, 35, leading from the end of the valve adjacent to the opening of the chamber 24, which communicates with the auxiliary reservoir, to the face of the valve, so as, at the limit of traverse of the piston-stem in the application of the brakes, to establish communication directly through said passage between the auxiliary reservoir and the port 23 and passages 22 and 16, leading to the brake-cylinder.

The piston-stem 13 abuts when the stem 13 and piston 12 are moved for the major portion of their traverse toward the drain-cup 19 against a stem, 36, which is fitted to slide freely in line axially with the stem 13 in an open-ended bushing, 37, in the end of the drain-cup 19 adjoining the piston-chamber 11, and in a guide formed in a screw-cap, 38, closing the opposite end of the drain-cup. A spring, 39, surrounding the stem 36 and bearing against the inside of the cap 38 and against a collar, 40, on the stem 36, maintains the latter in the position shown in Fig. 2, except when a sufficient pressure of air is admitted from the auxiliary reservoir to the piston-chamber to overcome the resistance of the spring and effect movement of the piston 12 beyond the point at which its stem 13 comes in contact with the stem 36.

So far as hereinbefore described, the triple valve accords in all

substantial particulars with and is adapted to operate similarly to those of my letters patent Nos. 168,359, 172,064, and 220,556, and, in order that it may perform the further functions requisite in the practice of my present invention, it is provided with certain additional members, which will now be described. For the purpose of effecting the admission of air directly from the main air-pipe 2 to the brake-cylinder 7 when it is desired to apply the brakes with great rapidity and full force, an auxiliary slide-valve, 41, is connected to and moves with the stem 36, said valve working over a face in the bushing 37 between the piston-chamber 11 and drain-cup 19, and governing a port, 42, in said face leading into a chamber, 43, adjoining the same. The valve 41 has lateral wings or plates fitting on each side of the stem 36, between shoulders or collars thereon, and is held thereto, when the stem is removed, between collars or shoulders thereon abutting against its ends, by a pin, 44, in its wings, a spring, 45, acting to hold it to its seat in the bushing 37 when in position. The chamber 43 communicates by a passage, 46, Fig. 5, with a chamber, 47, in the end of the case of the triple valve adjacent to the auxiliary reservoir, from which chamber a passage, 48, leads through the auxiliary reservoir into the brake-cylinder 7. The chamber 43 is further provided with a check-valve, 49, which opens outwardly into and controls the passage of air into the passage 46, said valve being held to its seat by a light spring, 50, and serving to prevent the return of air from the brake-cylinder when the pressure in the main air-pipe is reduced below that in the brake-cylinder, as in the case of the separation of the cars of the train by the breaking of a coupling.

In the operation of the brake mechanism as above described, air from the main reservoir and main air-pipe passes through the passages 17 18, drain-cup 19, and passages 20 into the piston-chamber 11, forcing the piston 12 to the left-hand extremity of its stroke and uncovering a small feeding-groove, 51, in the piston-chamber, through which air passes into the auxiliary reservoir 6 until the pressure in the latter is equal to that in the main air-pipe, the brake-cylinder being meanwhile in communication with the atmosphere through the passages 16 and 22, valve-cavity 33, and ports 23 34, and release-port 15. To apply the brakes in making ordinary stops, a portion of the air is discharged from the main air-pipe by the engineer's valve, thereby correspondingly reducing the pressure in the main air-pipe, whereupon the higher pressure in the auxiliary reservoir moves the piston 12 to the right, covering the feeding-groove 51, and thus preventing the return of air from the auxiliary reservoir to the main air-pipe, the movement of the piston continuing until arrested by the decrease of pressure in the auxiliary reservoir or by the stem 36 and its spring 39. The movement of the slide-valve 14 then closes the port 23, preventing escape of air from the brake-cylinder, and places the passage 31 partly or wholly in communication with the port 33. The small auxiliary valve 29 having been meanwhile unseated by the movement of the piston-stem, compressed air from the auxiliary reservoir passes through the lateral port 32 and passage 31 of the slide-valve 14 and the

passages 22 and 16 of the triple-valve case to the brake-cylinder, forcing out the piston, and, through an appropriate system of levers and connections, applying the brakes. When the pressure in the auxiliary reservoir has in this operation been reduced by expansion into the brake-cylinder until it is slightly below the pressure in the main air-pipe, the pressure on the air-pipe side of the piston 12 forces the piston 12 in the opposite direction until the auxiliary valve 29 closes the passage 31, thereby arresting the further flow of air from the reservoir to the brake-cylinder and holding the brakes with a force proportionate to the reduction of pressure in the brake-pipe. To release the brakes, the pressure in the main air-pipe is increased by admitting air from the main reservoir, whereupon the resultant increase of pressure in the piston-chamber

11 forces the piston 12 back to its original or normal position, 1282 permitting the escape of air from the brake-cylinder 7, the piston 52 of which is returned to its position by a spring, 53, releasing in its backward movement the brake-shoes 9 from the wheels, and at the same time the auxiliary reservoir is recharged. The admission of air to the brake-cylinder through the passage 31, which is opened just before the piston-stem comes in contact with the graduating-stem, and which corresponds to the feed-passage heretofore employed, suffices for the ordinary requirements of braking in regular service. In the event, however, of its becoming necessary to apply the brakes with great rapidity and with their greatest available force, the engineer, by means of the valve at his command, instantly discharges sufficient air from the front end of the main air-pipe to effect a sudden reduction of pressure of about twenty pounds per square inch therein, whereupon the piston 12 of the triple valve is forced to the extreme limit of its stroke in the direction of the drain-cup 19, carrying with it the stem 36 and auxiliary slide-valve 41, which instantly uncovers the port 42 and discharges air from the main air-pipe through the opening of the check-valve 49 and the passages 45 and 48 to the brake-cylinder, and, each car being provided with one of these devices, it will be seen that they are successively moved with great rapidity, there being practically on a train of fifty cars fifty openings for discharging compressed air from the main pipe, instead of the single opening heretofore commonly used. Not only is there a passage of considerable size opened from the brake-pipe on each car, whereby the pressure is more quickly reduced, but the air so discharged is utilized in the performance of preliminary work, it being found in practice that the air so taken from the pipe will exert a pressure of about twenty-five pounds in the brake-cylinders. When the piston 12 arrives at the extremity of its stroke, as above specified, the supplemental port 35 of the slide-valve 14 is brought into communication with the port 33 and passages 22 and 16, which serves to discharge the reservoir-pressure into the brake-cylinder, thereby augmenting the pressure already exerted in the brake-cylinder by the air admitted from the main air-pipe. Upon the reduction of the pressure in the main air-pipe below that in the brake-cylinders, as by the braking in two of the train, the check valve 49 closes communication between

the passages 46 and 18, thereby preventing the return of the air from the brake-cylinder to the main air-pipe. The feed-opening for the admission of air from the auxiliary reservoir to the brake-cylinder is purposely made of comparatively small diameter, it having been determined by experiment that the initial application of the brakes should not be made with maximum force, and this opening may be made of such size as to apply the brakes exactly in accord with the requirements of the most efficient work.

In using the terms "triple valve" and "triple-valve device" I refer to a valve device, however specifically constructed, having a connection with the main air or brake pipe, another with an auxiliary reservoir or chamber for the storage of power, and another with a brake-cylinder or its equivalent for the utilization of the stored power and with a release or discharge passage for releasing the operative power from the brake-cylinder, whether the valves governing these passages or connections are arranged in one or more cases and are moved by a piston or its equivalent or by a series of pistons or their equivalents, there being numerous examples in the art of constructions varying materially in appearance whereby these functions are performed, both in plenum and vacuum brake mechanisms.

While I have herein described my invention as applied in a brake mechanism utilizing air under pressure, such as is in general and approved use, I do not desire to limit myself to brakes so operated, as my improvements are likewise susceptible of application, without variation of principle, in connection with brakes worked by atmospheric pressure.

I am aware that a construction in which "an always-open one-way passage" from the main air-pipe to the brake-cylinder is uncovered by the piston of the triple valve simultaneously with the opening of the passage from the auxiliary reservoir to the brake-cylinder has been heretofore proposed, and such construction, which involves an operation different from that of my invention, I therefore hereby disclaim.

I claim as my invention and desire to secure by letters patent—

1. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, a triple valve, and an auxiliary-valve device, actuated by the piston of the triple valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake-cylinder, substantially as set forth.

2. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth.

3. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder and

effects a second admission of air from the auxiliary reservoir to the brake-cylinder, substantially as set forth.

4. The combination, in a triple-valve device, of a case 1283 & 1284 or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, and an auxiliary valve actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, substantially as set forth.

5. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, an auxiliary valve, actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, and a check or non-return valve interposed between the auxiliary valve and the passage leading therefrom to the brake-cylinder, substantially as set forth.

6. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, an auxiliary stem mounted in the cap of the case in position to be moved longitudinally by the piston-stem in the latter portion of its traverse in the direction required for the application of the brakes, a spring bearing against a collar on the auxiliary stem and against a fixed abutment, and an auxiliary valve connected to the auxiliary stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, substantially as set forth.

7. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, an auxiliary valve actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with a brake-cylinder, respectively, and a main valve connected to the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, said main valve having a supplemental port or passage which establishes communication between the auxiliary reservoir and brake-cylinder connections at or near the limit of the traverse of the main valve in effecting the application of the brake under maximum pressure, substantially as set forth.

In testimony whereof I have hereunto set my hand.

UNITED STATES PATENT OFFICE.

GEORGE WESTINGHOUSE, JR., of Pittsburg, Pennsylvania.

Fluid-pressure Automatic Brake Mechanism.

Specification forming part of Letters Patent No. 376,837, dated January 24, 1888. Application filed October 1, 1887. Serial No. 251,195. (No model.)

To all whom it may concern :

Be it known that I, George Westinghouse, Jr., residing at Pittsburg, in the county of Allegheny and State of Pennsylvania, a citizen of the United States, have invented or discovered certain new and useful improvements in fluid-pressure automatic brake mechanisms, of which improvements the following is a specification.

My present invention relates to appliances of the class exemplified in letters patent of the United States No. 360,970, granted and issued to me under date of March 29, 1887, and its object is to facilitate the application of brakes with great rapidity and full or approximately full force, as from time to time required, by the provision of means whereby the admission of air from the brake-pipe to the brake-cylinders may be effected as directly as practicable and through passages of as large capacity as may be desired.

The improvements claimed are hereinafter fully set forth.

In the accompanying drawings,

(Here follow diagrams marked pp. 1286, 1288, 1290, 1292)

Figure 1 is an inverted plan-view of a portion of a railroad-car, illustrating the application of my invention; Fig. 2, a longitudinal section, on an enlarged scale, through a valve mechanism embodying my invention at the line *ww* of Fig. 3; Fig. 3, a transverse section through the same at the line *xx* of Fig. 2; Fig. 4, a top view of the main slide-valve; Figs. 5 and 6, transverse sections through the same at the lines *yy* and *zz*, respectively, of Fig. 4; Fig. 7, a longitudinal section through the main slide-valve bushing, taken parallel to the valve-face thereof; Fig. 8, a longitudinal section through a valve mechanism, illustrating a modification of my invention at the line *vv* of Fig. 9; Fig. 9, a transverse section through the same at the line *uu* of Fig. 8; Fig. 10, a similar section through the supplemental valve casing at the line *tt* of Fig. 8; Fig. 11, a view in elevation of the supplemental valve seat; and Fig. 12 a longitudinal central section through a valve mechanism, illustrating a further modification of my invention.

As shown in Figs. 1 to 7, inclusive, my invention is applied in connection with a "triple-valve" device which in general structure and manner of operation, and saving as to the improvements hereinafter described, accords substantially with those set forth in my letters patent No. 220,556, dated October 14, 1879, and No. 360,970,

ATT'Y.

dated March 29, 1887. The operative mechanism of the triple valve proper is, as in said letters patent, inclosed within a case or chest, 10, which in this instance is secured to one end of the auxiliary reservoir 6, to the opposite end of which the brake-cylinder 7 is connected. The triple-valve case, auxiliary reservoir, and brake-cylinder are fixed in any convenient position on or under the sills or lower framing, 1, of the car, to which the main air or brake pipe 2, having the usual flexible connections and couplings, is likewise secured, and the brake-cylinder is fitted with a piston by the movements of which, through proper lever-connections, the brake-shoes are applied to and released from the wheels of the car.

The portion of the triple-valve case 10 which adjoins the auxiliary reservoir 6 is lined with an open-ended valve-bushing, 24, on which is formed the seat or valve face of the main slide-valve 14, the bushing 24 forming a chamber within which the valve is fitted to reciprocate, said chamber communicating at one end with the auxiliary reservoir and at the other with a bushing 11, forming the chamber of a piston, 12, secured upon the stem 13 of the valve 14. A cap or drain-cup, 19, is secured upon the end of the valve-case 10, in which the bushing 11 is fixed, and communicates with the chamber inclosed by said bushing through a series of ports, 20. A supplemental valve-chamber, 54, is cast upon or secured to the triple-valve case 10 on one side of the valve-bushing 14, said chamber being preferably formed in two sections, as shown, the inner of which is cast upon the triple-valve case and provided with lugs to which the outer or cap section is secured by bolts 55. The chamber 54 communicates by a passage, 17, with the main air or brake pipe 2, and by a passage, 16, with the brake-cylinder 7, communication between the passages 16 and 17 being opened and closed as required in setting and releasing the brakes by interposed valves 41 and 49, as hereinafter described.

The valve-bushing 24 is provided with ports 56, 57, 58, and 59, all of which are governed by the main slide-valve 14. The port 56 communicates with a channel or passage, 60, leading into the brake-cylinder passage 16. The ports 57 and 58, which are located in line transversely in the bushing, communicate with passages 61, (indicated in dotted lines in Figs. 2 and 3,) leading into the supplemental valve-chamber 54, and the port 59 communicates with a channel, 31, leading to the relief or exhaust port 15. The main slide-valve 14 is provided with a longitudinal passage, 31, extending from its end adjacent to the piston 12 to a point on its face, said passage being governed by a graduating-valve, 29, secured upon a stem, 30, which is fixed to the valve-stem 13 and receives a limited degree of traverse independently of the main slide-valve 14 in order to open and close the passage 31. To this end the collar 27 and shoulder 28 of the valve-stem by which the valve 14 is moved are, as heretofore, set at a distance apart slightly greater than the length of the valve. A lateral port, 32, establishes communication between the valve-face end of the passage 31 and the interior of the bushing 24 and auxiliary reservoir 6 when the graduating-valve 29 is moved off its seat in the passage 31.

A lateral recess or cavity, 66, is formed in the face of the valve 14 adjacent to the opening of the passage 31, in position to register with the port 58 when brought in line therewith in the movements of the valve, and an exhaust recess or cavity, 62, which is widened at one end to extend over the openings of both the ports 57 and 58, is formed in the face of the valve 14 adjoining its opposite end. The exhaust-recess 62 serves in one position of the valve to establish communication between the brake-cylinder and the release-port 15 through the passages 60 and 34, and in another to put the bottom of the supplemental valve-chamber in communication with the release-port through the passages 61, 57, 58, and 59. A supplemental port or passage, 35, leads from the end of the valve 14 adjacent to the auxiliary reservoir to a point on the face of the valve so located that at the limit of the traverse of the valve-stem and valve 14 in the application of the brakes communication will be established between the auxiliary reservoir and the brake-cylinder through the passages 35, 60, and 16.

A supplemental piston, 63, which may be provided with a packing-ring, is fitted to traverse in the end of the supplemental valve-chamber 54 adjacent to the triple-valve case 10, and in its movement outwardly therefrom to bear against the stem 64 of a supplemental valve, 41, which opens outwardly or in the direction of the brake-pipe passage 17, and is seated upon and over an opening in a transverse partition, 65, interposed between the two sections of the valve-chamber 54. A check-valve, 49, which opens inwardly and is seated adjacent to the outer end of the valve-chamber 54, governs communication between the same and the passage 17, leading from the brake-pipe thereto. A spring, 50, bears at its ends upon the stems of the valves 41 and 49, and acts to hold the same to their respective seats during such periods as a substantial equilibrium of pressure is maintained in the brake-cylinder and brake-pipe and when the valve 41 is not subjected to pressure by the piston 63. The check-valve 49 may, if desired, be omitted, the supplemental valve 41 being in such case held to its seat by a spring sufficiently strong to retain within the brake-cylinder a sufficient pressure to stop the train in the event of a rupture of the brake-pipe or of the escape of air therefrom by the train breaking in two.

In operation the application of the brakes under such fraction of the maximum force as is required for making ordinary stops is effected, as in my prior constructions, by discharging a portion of the air from the brake-pipe through the engineer's valve, the preponderance of pressure thereby induced in the auxiliary reservoir moving the piston 12, stem 13, and main slide-valve 14 in the direction of the drain-cup 19 until such movement is arrested by the decrease of pressure in the auxiliary reservoir or by the tension of the spring 39 on the stem 36, against which the stem 13 abuts. The graduating-valve 29 having been meanwhile unseated by the movement of the stem, compressed air from the auxiliary reservoir passes through the port 32, passage 31, passage 60 (with which in this position of the valve 14 the passage 31 communi-

cates,) and passage 16 to the brake-cylinder 6, forcing out the piston thereof and through the usual connections applying the brakes.

In making emergency stops, or when it is desired to apply the brakes with the greatest rapidity and greatest available force, sufficient air is discharged by the engineer to effect a sudden and material reduction of pressure—as, say, twenty pounds per square inch—in the brake-pipe, the effect of which is to force the piston 12 and main slide-valve 14 to the extreme limit of their stroke in the direction of the drain-cup 19. When in such position, the port 58 of the valve-bushing 24 will be opened by the valve-recess 66 and the port 57 by the port 32 and passage 31, permitting the passage of air from the auxiliary reservoir through the ports 57 and 58 and communicating passages 61 to the supplemental valve-chamber 54 on the inner side of its piston 63. The pressure thereby exerted upon the piston 63 forces the latter outwardly, its bearing in its outward movement upon the stem 64 of the supplemental valve 41 raising the latter from its seat, upon which the preponderance of pressure in the brake-pipe and connected passage 17 opens the check-valve 49 and admits air directly from the brake-pipe to the brake-cylinder through the passage 17, chamber 54, and passage 16.

It will be observed that the passages 17 and 16 may be made of as large diameter as desired without interfering with other portions of the mechanism, and that the traverse of the air from the brake-pipe to the brake-cylinder is comparatively short and direct.

When the main slide 14 has been brought into position 1295 to effect the admission of air from the brake-pipe to the brake-cylinder, as above described, its port 35 is in communication with the ports 56 and 60 and the pressure theretofore exerted in the brake-cylinder is augmented by that existing in the auxiliary reservoir, the air from which passes to the brake-cylinder through the ports 35, 56, and 60. Upon the reduction of pressure in the brake-pipe below that in the brake-cylinder the check-valve 49 is seated by the higher pressure on its inner side and by the spring 50, or, if equilibrium of pressure exists in the brake-pipe and brake-cylinder, by the spring 50, thereby preventing the return of air from the brake-cylinder to the brake-pipe.

In releasing the brakes the pressure in the brake-pipe is reinstated by the admission of air from the main reservoir, when the increased pressure, acting through the passage 17 and 18 and openings 20 upon the adjacent side of the piston 12, forces the latter and the connected main slide-valve 14 in the opposite direction, the first effect of which movement is to open the ports 61, 57, and 58 to the release-port 15 through the exhaust-cavity 62 of the valve 14, when the piston 63 is moved inwardly by the pressure upon its outer side, releasing the supplemental valve 41, which, together with the check-valve 49, is seated by the spring 50, thereby closing communication between the brake-pipe and brake-cylinder. The further movement of the valve 14 opens the passage 60 to the exhaust through the recess 62 and allows the air to escape from the brake-cylinder through said passage and recess, when the piston of the brake-cylinder is returned to its original position by a spring, releasing

the brake-shoes in its backward movement. The auxiliary reservoir is recharged, as heretofore, by air which passes through a small feeding groove in the chamber of the piston 12.

Figs. 8 to 11 show a modification in which a different form of supplemental valve is employed, the same being of the slide instead of the puppet type, as in the case first described. In this instance a central chamber, 67, is formed upon the partition or division plate 65 of the supplemental valve-chamber 54, the chamber 67 being open at its inner end to the section of the chamber 54 which is provided with the brake-cylinder passage 16, and communicating by a lateral port or opening, 68, formed in a valve face or seat, 69, on its side, with the outer section of the chamber 54, or that into which the brake-pipe passage 17 leads. The stem 70 of the piston 63 is prolonged to extend into the chamber 67, and carries a head, 71, fitting therein. A spring, 72, which bears against the head 71 and the end wall of the chamber 67, maintains the piston 63 at the inner extremity of its traverse, except when the piston is moved by the pressure of air admitted through the ports 61, as previously described. The supplemental valve 41 is a flat slide, which works on the valve-face 69, and is held to a proper bearing thereon by a spring, 73. The valve 41 is reciprocated to open and close, as required, the port 68 by the piston 63, a projection, 74, in the valve, which traverses in a longitudinal extension of the port 68, engaging a recess on the side of the head 71 of the piston-stem 70. A check-valve, 49, which opens inwardly and is seated by a spring, 50, is fitted to seat in the outer end of the chamber 54, and controls communication between the chamber 54 and brake-pipe passage 17. The operation is similar to that first described, the supplemental valve 41 being moved to open the port 68 by the piston 63 on the application of pressure to the latter from the auxiliary reservoir through the ports 57, 58, and 61 in the movement of the main slide-valve 14, and the check-valve 49 being thereupon opened by the pressure of air in the brake-pipe and passage 17 and admitting the same to the chamber 54 and brake-cylinder passage 16.

Another modification of my invention (shown in Fig. 12) is designed for use in connection with the ordinary or any desired form of triple valve for the purpose, as in the previous instances, of effecting quick and powerful action when required. The supply of air from the auxiliary reservoir and triple valve to the brake-cylinder 7 in the application of the brake, and its exhaust from the brake-cylinder in their release, is in this case effected through a piston-chamber, 75, which communicates with the triple valve by a passage, 76, formed on or fixed to its head or end plate, 77, and by ports or openings 78, leading out of said passage and through the head 77. The opposite end of the piston-chamber 75 communicates with the brake cylinder by a passage, 79, and a piston, 63, is fitted to work in the chamber between the ports 78 and passage 79. A port, 80, extends through the piston 63, said port being of a diameter not exceeding that which will suffice to admit and exhaust air to and from the brake-cylinder in ordinary braking—that

is to say, where full braking power is not desired to be exerted—so that in such case the air may pass directly to the piston of the brake-cylinder without moving the piston 63, while the sudden admission of a greater volume of air will impart movement to the piston. A valve-chamber, 54, which is connected or adjacent to the piston-chamber 75, communicates with the brake-cylinder 7 by a passage, 16, and with the main air-brake pipe by a passage, 17, communication between said passages being governed by a supplemental valve, 41, which opens outwardly or in the direction of the brake-pipe passage 17, and is normally seated by a spring, 50. The valve 41 is fixed upon a stem, 81, which extends into the piston-chamber 75 and bears at its end upon the piston thereof. The passage 17 may be provided with an ordinary check-valve opening inwardly to prevent the return of air from the brake-cylinder on a diminution of the pressure in the brake-pipe below that in the brake-cylinder.

In ordinary braking, air from the auxiliary reservoir and triple valve passes through the passage 76, ports 78, piston-chamber 75, and ports 80 and 79 into the brake cylinder to effect the application of the brakes, and is similarly discharged to the exhaust in their release. When the brakes are to be applied quickly and with full force, a greater quantity of air is suddenly admitted to the piston-chamber 75, and, not finding sufficient discharge through the port 80, moves the piston 63 in the direction of the valve 41, and through the stem 81, unseats said valve and admits air directly to the brake-cylinder from the brake-pipe through the passages 17 and 16 and chamber 54, as in the instances before described. In the release of the brakes the valve 41 is seated by the spring 50.

I claim as my invention and desire to secure by letters patent—

1. In a brake mechanism, the combination of a chamber or casing having direct connections to a brake-cylinder and to a brake-pipe, respectively, a valve controlling communication between said connections, and a piston or diaphragm which is independent of and unconnected with a triple-valve piston and is actuated by pressure from an auxiliary reservoir in direction to impart opening movement to said valve, substantially as set forth.

2. In a brake mechanism, the combination of a chamber or casing having direct connections to a brake-cylinder and to a brake-pipe, respectively, a valve controlling communication between said connections, a piston or diaphragm which is independent of and unconnected with a triple-valve piston and is actuated by pressure from an auxiliary reservoir in direction to impart opening movement to said valve, and a check or non-return valve controlling communication between said valve and the brake-pipe passage of the chamber, substantially as set forth.

3. In a brake mechanism, the combination, with a triple valve, of a supplemental chamber or casing having passages leading to a brake-cylinder and to a brake-pipe, respectively, a supplemental valve controlling communication between said passages, a supplemental piston operating independently of the triple-valve piston and adapted to impart opening movement to said supplemental

valve, and a passage establishing communication between said supplemental piston and an auxiliary reservoir, substantially as set forth.

4. In a brake mechanism, the combination, with a triple valve, of a supplemental chamber or casing having passages leading to a brake-cylinder and to a brake-pipe, respectively, a supplemental valve controlling communication between said passages, a piston adapted to impart movement to said valve, and a passage establishing communication between said piston and an auxiliary reservoir through the main slide-valve of the triple-valve mechanism, substantially as set forth.

5. In a brake mechanism, the combination of a triple valve having its main slide-valve and valve-bushing provided with ports and passages for the admission and exhaust of air from an auxiliary reservoir to and from a brake-cylinder and to and from a supplemental valve-chamber, a supplemental valve-chamber connected to the slide-valve chamber of the triple valve and having passages leading to the brake-cylinder and to the brake-pipe, respectively, a supplemental valve governing a port or opening in a partition of said chamber between said passages, a piston fitting said chamber above a port leading to the main slide-valve chamber in position to impart movement to the supplemental valve, a check-valve governing the brake-pipe passage of the supplemental valve-chamber, and a spring or springs acting to seat the supplemental and check valves, substantially as set forth.

6. In a brake mechanism, the combination of a triple-valve casing, a supplemental valve-chamber composed of an inner section which is formed integral with the triple-valve casing and a separable outer section, each having a lateral air pipe or passage, and a supplemental valve-seat formed in a division plate or partition interposed between and secured to the two sections of the supplemental valve-chamber, substantially as set forth.

In testimony whereof I have hereunto set my hand.

UNITED STATES PATENT OFFICE.

GEORGE ALBERT BOYDEN, of Baltimore, Maryland, assignor to the Boyden Brake Company of Baltimore City, of Maryland.

Valve for Air-brakes.

Specification forming part of Letters Patent No. 481,134, dated August 16, 1892. Application filed September 30, 1889. Serial No. 325,474. (No model.)

To all whom it may concern:

Be it known that I, George Albert Boyden, a citizen of the United States, residing at Baltimore, in the State of Maryland, have invented certain new and useful improvements in valves for air-brakes; and I do declare the following to be a full, clear, and exact description of the invention, such as will enable others skilled in the art to which it appertains to make and use the same, reference being had to the accompanying drawings, and to the letters of reference marked thereon, which form a part of this specification.

This invention relates to improvements in valve mechanism of automatic air-brake systems, and has for its principal object to provide for the admission of air-pressure to the brake-cylinder from both the train-pipe and the auxiliary reservoir, so as to affect a powerful application of the brakes, and at the same time produce a reduction of air-pressure in the train-pipe adjacent to the valve mechanism to quicken the application of succeeding brake mechanisms, so that the brakes on all the cars of the train will be applied at nearly the same instant.

In my patent of June 26, 1883, No. 280,285, I brought out an improved triple-valve mechanism having a check-valved passage from the train-pipe so arranged as to admit train-pipe air direct to the brake-cylinder at the same time that auxiliary-reservoir air is in the brake-cylinder. In my present invention I use the check-valved feed-passage of my 1883 patent, leading from the train-pipe through the triple-valve piston to the main valve-chamber, and thence both to the auxiliary reservoir and the brake-cylinder for the double purpose of supplying the auxiliary reservoir and also enabling train-pipe air to be vented directly through the main valve-chamber into the brake-cylinder to aid in applying the brakes in emergency stops.

Referring to the drawings,

(Here follow diagrams marked pp. 1298, 1300, & 1302.)

Figure 1 is an elevation showing the principal elements comprising an ordinary air-brake system and the application thereto of the improved valve mechanism by which the air-pressure is controlled. Fig. 2 is a view illustrating an air-brake cylinder, an auxiliary reservoir, a portion of the train-pipe, and the valve mechanism for controlling the air-pressure in the brake-cylinder,

the same representing the equipment of a single car. Fig. 3 is a view of the valve, looking toward the inner end, which is attached to the brake-cylinder. Fig. 4 is a longitudinal section through the valve mechanism on the line 4 4.

Similar letters of reference in the several figures indicate the same parts.

The brake system in general to which my present improvements are shown applied is that in common use, and includes, in addition to the brake-cylinder *C'*, auxiliary reservoir *R'*, and train-pipe *P'*, (illustrated in Fig. 2,) the usual equipment of the locomotive—such as an air pump or compressor, a storage-tank, and an engineer's valve *q*—all of which parts are familiar to persons skilled in the construction and operation of brake mechanisms.

In addition to the parts named a complete automatic air-brake system includes as one of its essential elements a valve mechanism located on each car and serving to control the admission and escape of air in the brake-cylinder for effecting the application and release of the brakes. This valve mechanism is popularly known as a "triple valve," and the present improvements relate more particularly to this element or part of the brake system and introduces a new mode of operation.

The valve-case shown comprises two pieces, the body part *A* and the head *A'*, which are suitably secured together. The open end *C* of the valve-case is attached in the present instance to the brake-cylinder *C'* by bolts passing through flange *u*, with an interposed gasket *v* for making a tight joint. The passage *R* connects with the auxiliary reservoir *R'*, the passage *P* with a branch *p*² of the train-pipe, and the passage *E* is for the exhaust from the brake-cylinder.

To economize space under the car, the auxiliary reservoir *R'* may be placed around the brake-cylinder *C'*, as shown, instead of being removed or separate therefrom, as is usual, and when so arranged communication is established between the auxiliary reservoir and the improved valve mechanism through a passage *w* in the head *x* of the brake-cylinder. It will be obvious, however, that it is

1304 not necessary to the operation of my improvements that the auxiliary reservoir should be thus constructed and arranged, as the usual forms of auxiliary reservoir and brake-cylinder will operate in unison with the improved valve mechanism with equal advantages.

The valve-case is provided with a piston-chamber *a* in open communication with the train-pipe connection or passage *P*, and in the present instance, this chamber is furnished with a bushing or lining *a'*, within which is fitted a piston *G*, having a central tubular extension *b* of smaller diameter than the piston and entering the valve-chamber *H* through an opening *c* at one end. This opening *c* is furnished with a bushing *c'*, which also serves as a guide for the said tubular extension *b*, which projects through it into chamber *H*. At its end this extension is furnished with a valve *F*, co-operating with the main valve-port *e* at the end of said chamber. This valve-port is formed by a bushing *e'*. When the port *e* is

open, air may pass from the valve-chamber H to the brake-cylinder C' by the openings C. The valve F is operated to open and close communication with brake-cylinder C' from both the auxiliary reservoir R' and train-pipe P'.

The main valve F is of the kind known as a "plug-valve," and is provided with a suitable packing *f* to make an air-tight fit in the port through the bushing *e'*. This valve F has a chamber *g*, terminating in a small port *g'*, and said chamber is lined by a tube *g*², provided with an end flange *g*³ for confining the packing *f*. The said small port *g'* serves to establish communication between the valve-chamber H and the brake-cylinder C' when the main valve F is in its closed position. This small port *g'* is controlled by the graduating-valve *h*, which has suitable grooves *h'* on its sides and fits movably in the lining-tube *g*². The conical end of the graduating-valve *h* is adapted to fit air-tight over the small port *g'*, and when unseated or moved to uncover the said port compressed air will pass from the valve-chamber H along the grooves *h'* and then to the brake-cylinder. The stem of the graduating-valve has a cross-slot, through which passes a pin *h*² for limiting the movement of the graduating-valve, and also serving to hold the lining-tube *g*² in position. The end of the stem of the graduating-valve projects beyond the lining-tube *g*², and when the main valve F is entered within the main port *e* sufficiently far the projecting end of the stem of said graduating-valve engages the stem *J'* of the release-valve.

The auxiliary reservoir R' and piston-chamber *a* are in communication through the passage R, formed in the valve case. Said passage supplies air on the side of piston G which is opposite the train-pipe passage P. This passage R does not lead through the valve-chamber H. The passage R between the piston-chamber and auxiliary reservoir is larger or of greater capacity than the passage *i*, through which air from the auxiliary reservoir is admitted to the valve-chamber H. The said passage *i*, through which auxiliary-reservoir air is conducted to the valve-chamber H in applying the brakes, is smaller—that is, it has a less transverse area and a restricted or smaller conducting capacity—than either the said passage R or the main port *e*, and it can conveniently be located, as shown, in the partition where the guide-bushing *e'* is fixed, which partition serves to separate or isolate the auxiliary-reservoir side of the piston-chamber *a* from the valve-chamber H, and thus makes it possible when applying the brakes in an emergency for the piston G to be subjected on its auxiliary reservoir side to a greater air-pressure than that contained in the valve-chamber H. A passage D is formed through the piston and extends from the train-pipe side of the piston-chamber *a* to the valve-chamber H, and in said passage is located a check-valve *d*, which is arranged to allow compressed air to pass from the train-pipe P' to the auxiliary reservoir R' for charging, and when the main valve-port *e* is open from the train-pipe direct to the brake-cylinder for quick action in emergency applications of the brakes; but said check-valve prevents air pass-

ing from the auxiliary reservoir and brake-cylinder back to train-pipe.

The construction of the check-valve *d* and its coacting parts may be varied from that shown. In the present instance guide-wings *d'* are connected to the valve, and the latter carries a packing *d²*. The check-valve is recessed, and a spiral spring *d³*, seated in said recess, presses the check-valve and keeps it normally on its seat *k'*, and when thus seated communication between the valve-chamber *H* and the brake-pipe is closed. The check-valve *d* is located in the tubular extension *b* of the piston, and passages *j* in said tubular extension *b* permit train-pipe air to pass into the valve-chamber *H*. In the tubular extension an internal tube or lining *k* is fitted, one end of which serves as a seat *k'* to the check-valve, while the other end *k²* projects at the opposite side of the piston *G* and serves as a handle or grasp part. The guide-wings *d'* of the check-valve slide in the internal tube *k*.

The check-valved passage *D*, through which train-pipe air flows when applying the brakes for an emergency stop, has a much greater area or capacity than the small passage *i*, through which the auxiliary-reservoir air flows. The nozzle *l*, for connection with the train-pipe *P'*, is formed on the head *A'* of the valve-case, and air under pressure is conducted from the train-pipe through said nozzle.

The exhaust-passage *E*, through which air is discharged from the brake-cylinder *C'* to the atmosphere to release the brakes, is controlled by a release-valve *J*, having a stem *J'*, sliding in a bearing *o*, which latter is supported by bridge-pieces *o'*. This passage extends through one of the bridge-pieces *o'*, and the openings 1305 *C* at the sides of said bridge-pieces form supply-passages communicating with the brake-cylinder. The release-valve *J* is in line with the graduating and main valves *h* and *F*, and these valves are so arranged that when the main valve is fully closed the end of the stem of the graduating-valve presses the stem *J'* of the release-valve and lifts the latter from its seat *p*. This valve-seat *p* is provided with a port *q'* in communication with a chamber *r* on one side and the exhaust-passage *E* on the other. The release-valve *J* is located within this chamber *r*, and the latter is in open communication with the brake-cylinder through passages *t*. A spiral spring *s* engages the release-valve and tends to keep it to its seat *p*.

It is well understood, that in valves of this general character a flexible diaphragm may be used as a recognized equivalent of the piston *G*. This and other equivalent changes may be made without in anywise departing from the present invention. In the present embodiment the valve-case is bolted by its flange to the head of the brake-cylinder in such manner that the passages *t*, communicating with the exhaust-passage, and the supply-openings *C*, communicating with the main and graduating valve-ports, will open to the brake-cylinder, while the large passage *R* is placed in communication with the auxiliary reservoir through a passage *w*, which in this instance is in the cylinder-head.

The operation of this improved valve mechanism is as follows: To charge the auxiliary reservoir and prepare the brakes for action, compressed air from the train-pipe entering through connecting-nozzle *l* acts upon the piston G and moves said piston, so that the graduating-valve *h* and the main valve F will close their respective ports and thus cut off communication with the brake cylinder C'. The exhaust-valve J will at the same time be moved to uncover its port, and the check-valve *d*, yielding to the preponderance of pressure exerted on its train-pipe side, will unseat, and air from the train-pipe will be conducted by passages D, *j*, *i*, and R to the auxiliary reservoir R'. An approximate equalization of air-pressure will thus be brought about in the auxiliary reservoir R', valve-chamber H, and train-pipe, and the check-valve will be seated. When it is desired to gradually apply the brakes, the handle of the engineer's valve *q* will be moved for a moment to such a position that communication between the storage-tank *y* on the locomotive and the train-pipe P' will be closed and an escape-orifice opened to the atmosphere. Thereby the air-pressure in the train-pipe will be reduced slightly—say about five pounds or less. This reduction of pressure on the train-pipe side of the piston G disturbs the balance previously existing on opposite sides thereof, resulting in establishing a preponderance of air-pressure on the auxiliary-reservoir side, and the air delivered from the auxiliary reservoir through the passage R and acting upon the piston G causes the latter and its attached parts to move outward and permit the release-valve J to seat, thereby closing communication between the brake-cylinder C' and the exhaust-passage E. This outward movement of the piston G will continue after the release-valve J has become seated and until the graduating-valve *h* has been unseated by the pressure of air in the valve-chamber H, thus allowing auxiliary-reservoir air to flow through small port *g'* into the brake-cylinder C', where it acts upon the piston thereof to effect the application of the brakes. When by reason of the flow of air into the brake-cylinder the pressure in valve-chamber H and in auxiliary reservoir R' has been reduced to or below that in the train-pipe, a slight return or inward movement of the piston G will be produced sufficient to cause the reseating of the graduating-valve *h*, and thus close communication between valve-chamber H and the brake-cylinder and confine the air admitted within the latter. In case it is desired to gradually increase the air-pressure in the brake-cylinder, the above-described operation is repeated. To permit the air in the brake-cylinder to escape and effect the release of the brakes, the air-pressure in train-pipe is restored or increased by a proper movement of the engineer's valve. The increase of pressure in the train-pipe causes the piston G to move inward to the limit of its stroke, when it will occupy the position illustrated in Fig. 4, thereby raising the release-valve J from its seat and placing the brake-cylinder in communication with the exhaust-passage E and allow the air to escape. At the same time the restoration of pressure in the train-pipe will unseat the check-valve *d* and air from the train-pipe will flow into the auxiliary reservoir, recharging the latter for future use. The recharging will

continue until the pressure in the auxiliary reservoir equals that in the train-pipe, when the check-valve will be seated by its spring. When it becomes necessary or desirable to apply the brakes of a train quickly and with full power for an emergency stop, the engineer's valve *q* will be moved to close communication between the storage-tank *y* and train-pipe and open the latter to the atmosphere and produce a sudden reduction of pressure of about ten or fifteen pounds in the train-pipe. The effect of this sudden diminution of pressure in the train-pipe is immediately manifested at the nearest valve mechanism or that on the first car, causing the valve-piston *G* to be moved by the higher pressure of auxiliary-reservoir air quickly to its full outward position, thus moving the main valve *F* and opening wide the main port *e*, so that the air-pressure contained in the valve-chamber *H* may exhaust freely into the brake-cylinder. The supply of air from auxiliary reservoir to the valve-chamber *H* is conducted through the restricted or small passage *i*. Hence when the main port *e* is opened wide and the air in valve-chamber escapes through the larger passage thus

1306 provided the pressure in said valve-chamber is quickly reduced below that in the piston-chamber *a* on the auxiliary-reservoir side. This follows because the passage *i*, supplying auxiliary-reservoir air to the valve-chamber *H*, is so much smaller than the passage *R*, supplying the same kind of air to the piston-chamber. The sudden and full opening of the main port *e* allows all or nearly all of the air-pressure on the brake-cylinder side of the check-valve *d* to escape, whereupon the check-valve will be immediately unseated and train pipe air will pass directly into the brake-cylinder *C'*, thus effecting the quick application of the brakes and also a further reduction of pressure in the train-pipe that will be sufficient to accelerate the action of the valve mechanisms on the cars following. The piston *G* will in the meantime be held to its outward position by the relatively higher air-pressure from the auxiliary reservoir, which is delivered through the large passage *R*, while the transmission of auxiliary-reservoir air to the brake-cylinder is retarded by having to pass through the relatively smaller passage *i*. During its preliminary traverse outward or toward the train-pipe side the piston *G* operates to close the exhaust-passage, and its farther or continued movement in the same direction opens the main valve *F* and allows air to pass from both the auxiliary reservoir and the train-pipe to the brake-cylinder when making a quick application of the brakes. It will be observed that the valve mechanism depends for its action upon the movements of the piston *G* and that the latter is subjected to two opposing forces—auxiliary-reservoir air on one side and train-pipe air on the other—and that its movement in one direction is effected by the preponderating pressure of auxiliary-reservoir air, while its movement in the opposite direction results from a preponderance of pressure on the train-pipe side. If the passage *i*, through which auxiliary-reservoir air must flow upon the sudden opening of the main-valve port *e* for an emergency stop, was as large as or larger than the check-valved passage for supplying train-pipe air, the quick action referred to

and the utilization of train-pipe air direct in the brake-cylinder could not be effected for the very obvious reason that the inward flow of train-pipe air at, say, fifty-five or sixty pounds, to the brake-cylinder would be opposed and checked by the flow of auxiliary-reservoir air at a higher pressure, say, seventy pounds; but by restricting the passage through which auxiliary-reservoir air is conducted in the course of its transmission to the brake-cylinder, so that its capacity for the flow of air will be less than that of the main port *e* and less than the check-valve passage leading from the train-pipe, a considerable volume of train-pipe air will flow into the brake-cylinder, notwithstanding the admission of the auxiliary-reservoir air under a higher pressure, because the flow of auxiliary-reservoir air is so retarded by the smaller passage *i*, through which it is conducted, that an appreciable period of time is required to raise the pressure in the brake-cylinder to that in the auxiliary reservoir, and it is during this interval and before the pressure in the brake-cylinder is raised to that in the train-pipe that the air in the latter is free to enter the brake-cylinder. It will thus be seen that the sudden uncovering of the main port or passage *e*, leading to the brake-cylinder, by the movement of the main valve opens communication between the train-pipe and brake-cylinder and also between the auxiliary reservoir and the brake-cylinder; but that the flow of the higher-pressure air from the auxiliary reservoir into the brake-cylinder is retarded by being compelled to traverse a relatively small orifice or passage, while the lower-pressure train-pipe air is permitted to flow through a larger orifice or passage.

From the foregoing explanation it is obvious that there is a co-action at the time of applying the brakes for emergency stops between the restricted passage which supplies auxiliary reservoir air, the larger passage which supplies train-pipe air, and the single valve which controls the communication of air from both of said passages to the brake-cylinder. As soon as the pressure above the check-valve caused by the auxiliary-reservoir air, plus the pressure of the spring *d^b*, exceeds the pressure exerted by the train-pipe air on the other side, the check-valve will close and the further ingress of train-pipe air to the brake-cylinder will be cut off, while the auxiliary-reservoir air will continue to flow, thus augmenting the pressure therein. To effect the release of the brakes, the air-pressure must be restored in the train-pipe to overcome the pressure on the auxiliary-reservoir side of the piston G, whereupon the parts will act in the manner already described.

As hereinbefore intimated, this valve mechanism belongs to the class of air-brake valves known as "triple valves," of which there are numerous examples, differing somewhat in construction and embodying variations and modifications in the form and arrangement of parts; but all of them, however specially constructed, contemplate a valve structure having suitable connections for the train-pipe, the auxiliary reservoir, and the brake-cylinder, and are provided with passages or ports leading, first, from the train-pipe to the auxiliary reservoir; second, from the said reservoir to the brake-cylinder, and, third, from the brake-cylinder to the atmos-

phers; hence the name triple valve. In some cases a plurality of valves govern these passages or ports.

It is to be observed that some of the distinguishing features of this invention are, first, that provision is made whereby train-pipe air may pass direct to the brake-cylinder through the triple valve, thus utilizing the triple-valve mechanism to effect what is 1307 known as a "quick action" of the brakes without necessitating the use of an "auxiliary" valve, as heretofore; second, quick action of the brakes is produced by the admission of both auxiliary-reservoir air and train-pipe air to the brake-cylinder by use of a single valve and properly proportioning the passages of the triple valve, so that train-pipe air at a lower pressure than that in the auxiliary reservoir may be admitted to the brake-cylinder; third, the novel mode of operation, whereby in applying the quick-action feature three different pressures are momentarily produced in the triple-valve case—that is, the highest pressure on auxiliary-reservoir side of piston, a lower pressure on the train-pipe side of said piston, and the lowest pressure where the port *e* is located, which leads to the brake-cylinder.

In the embodiment shown the main valve of the triple valve is of the reciprocating plug form, which is deemed advantageous, in that it admits of a certain extent of reciprocating movement within its port *e* without opening or uncovering the latter, so that the unintentional slight variations of air-pressure that occur in the train-pipe will be productive of no disadvantage, as the piston *G* can have a limited movement without allowing any air to pass. Another advantage of this "plug" form of valve is that it permits the closing of the release-valve before the opening of the ports controlled by it and by the graduating-valve. These specific improvements in form, while advantageous in the particulars mentioned, do not affect the new mode of operation due to the reorganization of the triple valve and which results in the addition thereto of a new function. My invention therefore is not limited to this form of valve.

As ordinarily constructed heretofore the triple valve has been arranged to effect two grades of brake application by use of auxiliary-reservoir pressure alone, these two grades differing in degree rather than in kind. The first may be called "full pressure" and the second is known as "graduation." For effecting these two grades of application a main and a graduating valve are employed, corresponding generally, though embodied in different forms, with the main graduating-valves *F* and *h* here shown. These, together with a release-valve and feeding-valve, are usually arranged to be actuated by a piston.

An example of the class of triple valves just referred to is shown in United States patent to George Westinghouse, Jr., dated October 14, 1879, No. 220,556. Triple valves of this kind and in a great variety of forms are well known; but they do not possess the quick-action principle, which utilizes train-pipe air in the application of the brakes and effects a reduction of train-pipe pressure by

so doing. On the contrary, in such valves the pressure available in the brake-cylinder is derived from the auxiliary reservoir alone.

Efforts have heretofore been made to combine with a triple valve certain additional mechanism by which train-pipe air could be introduced directly into the brake-cylinder in effecting the application of the brakes for emergency stops; but in every such instance a supplemental passage or passages, together with a supplemental or auxiliary valve, has had to be employed in connection with the triple valve proper, in order that the ordinary functions of the triple valve might be preserved and the additional function of introducing train-pipe air into the brake-cylinder for emergency stops be combined therewith.

An example of the class of valves referred to in the last preceding paragraph which employ an auxiliary valve, combined with an ordinary triple valve, is shown in United States patent to George Westinghouse, Jr., dated March 29, 1887, No. 360,970.

It will be seen that my present invention for introducing train-pipe air into the brake-cylinder for emergency stops differs essentially from the device shown in the said patent No. 360,970, because I have provided a new principle of construction and a new mode of operation, by use of which the desired result aforesaid may be produced without the aid of the auxiliary valve heretofore required for the purpose.

An examination of the particular embodiment of the present invention will disclose the fact that it is a triple valve *per se*, without auxiliary or supplemental valve devices, and, further, that its conversion into a quick-action valve and its greater capacity for action over ordinary forms of triple valves is due to means which I have invented for retarding or restricting the flow of auxiliary-reservoir air to the main port or passage leading to the brake-cylinder as compared with the more open or free delivery of train-pipe air to the said main port or passage. By thus delaying or restraining the flow of auxiliary-reservoir air it becomes possible to open both passages to the brake-cylinder, and the difference in size of these passages allows a considerable portion of the air from the train-pipe at lower pressure to enter the brake-cylinder before the air from auxiliary reservoir at higher pressure raises the pressure in the brake-cylinder to such a degree as to prevent the ingress of train-pipe air, and, further, a single valve—the main valve of the triple valve proper—is here made to perform the office of opening communication to the brake-cylinder from both the train-pipe and the auxiliary reservoir in the quick application of the brakes for emergency stops. My invention therefore includes any form of structure of valve wherein a single valve admits both train-pipe air and auxiliary-reservoir air to the brake-cylinder in applying for emergency stops, and which structure is provided with means for restricting or retarding the flow of auxiliary-reservoir air to the brake-cylinder as compared with the flow of the train-pipe air thereto.

1308 The graduating-valve *h* of the present valve mechanism performs the ordinary functions of such a device and is

brought into useful action only in making "graduation" applications of the brakes. It does not affect in any manner the "quick-action" or emergency-stop feature. Hence its presence or absence is not essential thereto.

Having thus explained the principle of my invention and described means by which it may be embodied and practiced, what I claim as new, and desire to secure by letters patent, is—

1. In triple-valve mechanism for automatic air brakes, the combination of a passage from the train-pipe, a passage from the auxiliary reservoir, which is smaller or more restricted than said train-pipe passage, and a single valve coacting with both of said passages and controlling communication between them and the brake-cylinder, whereby when an emergency application of the brakes is desired the train-pipe air and auxiliary-reservoir air, the former at lower pressure than the latter, will both pass to the brake-cylinder through the triple valve.

2. In valve mechanism for automatic air-brakes, the combination of a communication with the brake-cylinder from both the auxiliary-reservoir and train-pipe, a single valve controlling said communication, and means to retard or restrict the flow thereto of the auxiliary-reservoir air when applying the brakes in comparison with the flow of train-pipe air, whereby train-pipe air at lower pressure than said auxiliary-reservoir air will pass said valve when making an emergency application of the brakes.

3. In a triple valve, the combination, with a suitable chamber, of a port therefrom to the brake-cylinder, a valve controlling said port, and passages to the said chamber from the train-pipe and from the auxiliary reservoir, the latter passage being of less capacity than the former, whereby train-pipe air may pass direct to the brake-cylinder through the triple valve to effect quick action of the brakes for emergency stops.

4. In a valve for automatic air-brakes, the combination of a communication with the brake-cylinder, a suitable valve controlling said communication, two air-passages coacting with said valve and relatively proportioned as to their capacity to allow the flow of both train-pipe air and auxiliary-reservoir air each at a different pressure to pass said valve when open, and a check-valve to prevent the return of air to the train-pipe.

5. A valve for controlling automatic air-brakes, having, in combination, a piston which is moved in one direction by pressure from the train-pipe and in the other direction by pressure from the auxiliary reservoir, a valve-chamber which has a check-valved communication from the train-pipe, a communication with the auxiliary reservoir, and a port communicating with the brake-cylinder, said port being of greater area or capacity than the said communication with the auxiliary reservoir, and a valve controlling said port and moved by the piston, whereby when the said port is opened the pressure in the valve-chamber will be reduced momentarily below that in the train-pipe, and air from the latter will thereupon pass to the brake-cylinder.

6. In a triple valve for automatic air-brakes, the combination of

a chamber having a port leading to a brake-cylinder, a passage opening into said chamber and which supplies auxiliary-reservoir air thereto, a piston-chamber and piston, a valve controlling said port and operated by a piston, and a passage from the auxiliary reservoir direct to said piston-chamber and avoiding the chamber first mentioned and which is larger or of greater capacity than the said passage which supplies auxiliary-reservoir air.

7. In valve mechanism for automatic air-brakes, the combination of a piston-chamber, a piston, a valve-chamber having a brake-cylinder port, a passage for supplying auxiliary-reservoir air when applying the brakes, which passage is smaller or of less capacity than said port, a passage to supply train-pipe air when applying the brakes, a valve in the valve-chamber coacting with said port, and controlling the flow of air to a brake-cylinder from both a train-pipe and an auxiliary reservoir, and a passage from the auxiliary reservoir to the said piston-chamber, and which in its course avoids the said valve-chamber.

8. In a triple valve for automatic air-brakes, the combination of a valve-chamber having a port leading to the brake-cylinder, a piston-chamber and piston, a passage from the auxiliary reservoir direct to the piston-chamber and which avoids the said valve-chamber, a passage which is smaller or more restricted than either the said port or the said direct passage to the piston-chamber, this small passage opening into the valve-chamber, and a valve controlling said port and operated by the piston.

9. In a triple valve for automatic air-brakes, the combination of a chamber having a port communicating with the brake-cylinder, a piston-chamber and piston, a passage from the train-pipe to the ported chamber, a partition provided with a passage which is smaller or more restricted than either the said port or the train-pipe passage, said partition serving to partially separate the ported chamber from the said piston-chamber, and a valve moved by said piston and controlling said port, whereby both train-pipe air and auxiliary-reservoir air may pass the same valve-port for an emergency stop.

10. The combination, in valve mechanism for air-brakes, of a piston, valve-chamber having a communication with a brake-cylinder, one from the train-pipe and another through a throttled or more restricted passage from the auxiliary reservoir, a valve to govern the communication leading to the brake-cylinder, 1309 & 1310 a tubular extension of the piston entering the valve-chamber and moving the valve and containing a passage which forms the said communication between the train-pipe and valve-chamber and a check-valve controlling said last-named passage.

11. In valve mechanism for automatic air-brakes, the combination of a main port communicating with a brake-cylinder from both the train-pipe and the auxiliary reservoir, a suitable valve controlling said main port, a graduating-valve which admits air-pressure in small volume to the brake-cylinder, and air-passages coacting with said main port and relatively proportioned as to their capacity to allow both train-pipe air and auxiliary-reservoir air, each at a

different pressure, to pass to said main port when the latter open.

12. In valve mechanism for automatic air-brakes, the combination of a chamber having a main port leading to the brake-cylinder, a reciprocating valve of plug form coacting with said main port and capable of a certain extent of movement without opening the said port, a graduating-valve *h*, fitting loosely in said plug-valve, and a release-valve unconnected with the said main valve and controlling an air-escape port.

In testimony whereof I affix my signature in presence of two witnesses.

1315 UNITED STATES PATENT OFFICE.

GEORGE A. BOYDEN, of Baltimore, Maryland, assignor to the Boyden Brake Company of Baltimore City, of Maryland.

Fluid-pressure Brake.

Specification forming part of Letters Patent No. 481,135, dated August 16, 1892. Application filed March 6, 1891. Serial No. 384,012. (No model.)

To all whom it may concern :

Be it known that I, George A. Boyden, a citizen of the United States, residing at Baltimore, in the State of Maryland, have invented certain new and useful improvements in fluid-pressure brakes, of which the following is a specification.

This invention relates to the construction of valves for automatic air-brakes, and has for its object to provide for admitting air-pressure to the brake-cylinder from both the train-brake pipe and the auxiliary reservoir, thereby effecting a more powerful and also a quicker application of each brake and at the same time so quickly reducing the air-pressure in the train-brake pipe adjacent to the said valves that all the brakes of a train will be applied at nearly the same time.

Referring to the drawings,

(Here follow diagrams marked pp. 1312 & 1314)

Figure 1 is a section of the auxiliary reservoir and brake-cylinder, with a side view of the valve and train-pipe. Fig. 2 is a cross-section of the reservoir, with a side view of the valve attached thereto, showing the passages by which communication is established between the reservoir and the valve and brake-cylinder. Fig. 3 is a longitudinal section of the valve. Fig. 4 is a side view of the valve-piston and its attached parts.

In my patent of June 26, 1883, No. 280,285, I brought out an improved triple-valve mechanism having a check-valve passage leading from the train-pipe through or around the piston to the main-valve chamber, with a communication to the auxiliary reservoir and a communication to the brake-cylinder, the latter communication being normally covered by the main valve of the triple-valve device and uncovered by the movement thereof, thus utilizing both auxiliary-reservoir air and train pipe air when the brakes are applied. Subsequently George Westinghouse, Jr., for the purpose of utilizing train-pipe air, in addition to auxiliary-reservoir air for applying the brakes in quick action, adopted a check-valved passage leading from the train-pipe around or past the triple valve directly to the brake-cylinder without passing through the main-valve chamber and covered said passage with a valve additional and "auxiliary" to the triple-valve mechanism, said auxiliary valve

performing none of the three ordinary functions of the latter, but adapted and used solely for producing a "quick action" of the brakes in applying for emergency. The United States patent for the Westinghouse invention here referred to is dated March 29, 1887, and numbered 360,070.

In my present invention I use the check-valved feed-passage of my 1883 patent, leading from the train-pipe through the triple-valve piston to the main-valve chamber, and thence both to the auxiliary reservoir and the brake-cylinder for the double purpose of supplying the auxiliary reservoir, and also enabling train-pipe air to be vented directly through the main-valve chamber into the brake-cylinder to aid in applying the brakes for emergency stops, and this is done without interfering with the usual operation or functions of the "triple valve" and also without the aid of the "auxiliary valve," heretofore required for the purpose. It will be seen that the means I have thus provided for introducing train-pipe air into the brake-cylinder for "emergency stops" differs, essentially, from that shown in said patent No. 360,070, and that said means involves a new mode of operation.

The branch pipe 33 from the train-pipe 34 is connected to the valve by its nozzle 1 and union-nut 2, which screws thereon, the intervening joint between being made tight by a washer. The valve-case is provided with a drip-chamber E, extending below to drain the water therefrom and from which it is drawn off by removing the plug 4. The cap 3 is secured to the body 5 by suitable bolts 6 and the joint between is made tight by a washer. The body-piece 5 of the valve is provided with a cylinder D, lined with a brass bushing 8, a large passage A communicating between the auxiliary reservoir and said piston-cylinder a valve-chamber C, having at one end an opening lined with a brass bushing 9, which serves in part as a partition and separates the piston-chamber D from the valve-chamber C. A small passage B opens in the present instance between the piston-chamber D and the valve-chamber C and forms a communication through which air from the auxiliary reservoir is admitted to the valve-chamber C, and vice versa.

1316 At the opposite end of the valve-chamber is a bushing 10, forming a port c, which is closed by the main valve 22. At this end of the body-piece is a passage g, leading to the brake-cylinder, and a bushing 11, having an exhaust-passage G opening to the atmosphere. It is obvious the restricted communication by which auxiliary-reservoir air flows to the valve-chamber may open directly between the auxiliary-reservoir passage A and the valve-chamber, as at B' in dotted lines. However located, this passage is much smaller than the passage A between the piston-cylinder D and the auxiliary reservoir. The piston 29 is provided with a packing-ring 30 and moves in the cylinder D, according to the changes in the preponderance of the pressure. Integral with the piston is the sleeve F, which fits and moves in the bushing 9. A cap 25 is secured to the sleeve F by the screw 21, which passes cross-wise through the cap and also through a stem 18 and has each end resting in the piston-sleeve F.

A bushing 11 is fitted in an opening at the end of the body-piece 5. This bushing has a central passage *h* and an annular passage *h'*. A release-port *i* connects said two passages, and the annular passage has a connection with the exhaust-passage G. A cap 12 fits into the bushing, and a washer 13 makes a tight joint between the cap and bushing. The cap has a central passage, conforming in size to the central passage *h* of the bushing, and is practically a continuation thereof. The release-port *i*, before mentioned, is formed where the inner end of the cap adjoins the annular passage *h'*. In this cap is arranged an abutting piece 14, which has a limited movement by means of a slot *j* and the pin 15. A spring 16 presses against the abutting piece 14 and forms a resistance in graduating to the end of the stem 18 and to the movement of the piston 29 and its attached parts. The release-valve is formed by a leather cup 17, secured to the valve-stem 18 by a screw 19, which extends into the stem, and a washer 20, that binds the said cup. The release-valve is movable like a piston in the central passage *h* of the bushing 11 and cap 12 and opens and closes the release-port *i*. The graduating-valve is formed by the valve-stem 18, having a passage *o*, with an opening *k* at one end, a port *k'* at the other, and with the main valve 22 loose on the said stem 18. The main valve 22 closes the large port *c*, which leads to the brake-cylinder, and this valve seats on the packing-rings 23 and 24. This valve 22 is loose on and is movable lengthwise of the stem 18, which wholly supports it. I term it a "floating" valve because it rides and may move freely on the stem and when unseated from the port *c* is not in contact with any other part. In the piston-sleeve F is arranged in a relation similar to my said 1883 patent the check-valve 26, which is held closed by the spring 27, the seat of the check-valve being formed by the packing-ring 28. The piston-sleeve forms the train-pipe passage and has openings *o'*, which communicate with the valve-chamber C. The partition where the guide-bushing 9 is located isolates or separates the auxiliary-reservoir side of the piston-chamber D from the valve-chamber C, and this makes it possible when fully applying the brakes in an emergency for the piston 29 to be subjected on its auxiliary-reservoir side to a greater air-pressure than that contained in the valve-chamber.

As shown in Fig. 1, the auxiliary reservoir I is attached to the brake-cylinder J, in which moves the piston L. The valve-body 5 is attached to the side of the auxiliary reservoir by the studs and nuts 35, and the large passage A communicates with the auxiliary reservoir I through the passage *m*. Communication between the valve and the brake-cylinder J is established through the curved passage P, connecting with the passage *g* in the valve.

Triple valves heretofore extensively in use, like that patented to George Westinghouse, Jr., October 14, 1879, No. 220,556, have been arranged to effect two grades of brake application by auxiliary-reservoir pressure. The first grade may be called "full pressure," and the second grade, which is partial pressure, is known as "graduation." For effecting these two grades of application a main valve and a graduating-valve have been employed corresponding gener-

ally, though embodied in a different form, with the main and graduating valves 22 and k' . (Here shown.) The graduation-valve $k' o k$ in the stem 18 of the present valve mechanism performs the ordinary functions of such a device and is brought into useful action only in making graduation applications of the brakes. This graduation-valve does not affect the action of the release-valve or the main valve 22, which latter will allow the flow to the brake-cylinder of auxiliary-reservoir air alone, and also allow the flow of both auxiliary-reservoir air and train-pipe air. It will therefore be seen that the presence or absence of the graduation-valve is not essential to the performance by the other parts of all the functions of a triple valve.

The operation of the valve is as follows: To charge the auxiliary reservoir, the air from the train-pipe passes in through the nozzle 1 and moves the valve-piston 29 to the position shown in Fig. 3, where the graduating-valve port k' and the main-valve port c will be closed, and thus all communication with the brake-cylinder cut off. The air then opens the check-valve 26 and passes through the openings o' in the sleeve F to the valve-chamber C, from which it passes through the small passage B into the piston-cylinder D, and thence through the large passage A to the auxiliary reservoir. An equalization of air-pressure will thus be brought about in the
 1317 auxiliary reservoir I, valve-chamber C, and train-pipe, and the check-valve 26 will be seated.

To apply the brakes by graduation, a slight reduction of the pressure in the train-pipe moves the piston 29 and its attached parts until the shoulder q on the stem 18 comes against the main valve 22, (the main valve remaining immovable on its seat, owing to the air-pressure in the valve-chamber C holding it thereon.) This movement closes the release-valve port i and draws the graduating stem 18 through the main valve 22 sufficiently far to expose the graduating-port k' in the valve-stem to the air-pressure in the valve-chamber C. The air then passes from the auxiliary reservoir by way of the large passage A and small passage B into the valve-chamber C, and then through the graduating-port k' passage o , and opening k in the valve-stem and the passage g to the brake-cylinder, where it effects the partial application of the brakes. This operation, which does not open the main-valve port, is due to the fact that the restricted communication B, through which the auxiliary-reservoir air enters the valve-chamber C, is larger than the graduating-port k' , and therefore the pressure in the valve-chamber is kept substantially equal to that in the auxiliary reservoir. This retention of the pressure in the valve-chamber when graduating holds the main valve 22 and the check-valve 26 seated on their respective ports. As the main valve 22 remains immovable on its port at the time the brakes are being applied by the graduation-valve, it serves to arrest the movement of the piston by means of the stop-shoulder q on the stem coming in contact with it. The piston 29 and its attached parts will remain in the same position—to wit, with the stem-shoulder q in contact with the main valve 22—until the pressure has been reduced in the auxiliary reservoir below that in the

train-pipe. The greater train-pipe pressure will then cause the piston 29 to move to the right till the end of the valve-stem 18 comes in contact with the spring-held abutting-piece 14, which retards the movement. When in this last position, the graduating-port k' in the valve-stem 18 is closed by having passed into the main valve 22, and thus prevents any further accumulation of pressure in the brake-cylinder. While in this position the cup-valve 17, which controls the release of the air, has not moved sufficiently far to uncover the release-port i , that leads to the atmosphere, and thereby holds the pressure in the brake-cylinder, which exerts the desired braking force. If it is desired to gradually increase the pressure in the brake-cylinder, the above operation may be repeated. To release the brake, the engineer's valve is moved, and thereby the maximum pressure is restored in the train-pipe, which, acting on the piston 29, overcomes the resistance of the abutting spring 16 and moves the piston and its attached parts to the right to the extreme limit of its movement, as shown in Fig. 3, which causes the release-valve 17 to uncover the release-port i and allow the air to pass from the brake-cylinder back through the passage g , then into the central passage h , around the stem 18, through the port i , and from thence to the annular passage h' in the bushing 11, from which it passes through the passage G to the atmosphere. At the same time that the brakes are released the restoration of the pressure in the train-pipe will recharge the auxiliary reservoir for future use. The brakes may be applied fully in two ways: first, by the auxiliary-reservoir pressure alone, and, second, by the auxiliary-reservoir pressure in conjunction with the train-pipe pressure. The first mode is used when an ordinary gradual stop is required, such as at a station. The second mode is used when an emergency stop is required, such as upon the occurrence of an accident. To apply the brakes fully for an ordinary stop, a limited amount of train-pipe air is continuously discharged from the engineer's valve, which reduces the pressure in the train-pipe and slowly moves the piston 29 to the left and opens the main valve 22 sufficient to practically maintain the same air-pressure on both sides of the said piston. The piston and the said valve will be retained in the position just mentioned, or the piston will slightly vibrate back and forward, causing the valve 22 to repeatedly unseat and seat by the discharge of the auxiliary-reservoir air (through the valve-chamber C to the brake-cylinder) being about equal to the continuous discharge of air from the train-pipe at the engineer's valve. Under these conditions the pressure in the brake-cylinder, valve-chamber C, and auxiliary reservoir will equalize, and thus the ordinary function of the triple valve in applying the brakes fully by the auxiliary-reservoir pressure alone is accomplished. If the train-pipe pressure continues to lower slowly, the piston and its attached parts will be moved their full stroke to the left; but the air from the train-pipe will not pass to the brake-cylinder, because by this continuous but limited discharge of train-pipe pressure the air-pressure in the valve-chamber C will not be suddenly reduced below that in the train-pipe, as in this operation the main valve will not be opened sufficiently to discharge

more air than the passage B supplies. To apply the brakes of a train quickly and with full power for an emergency stop, the engineer's valve will be moved to close communication between the storage-tank on the locomotive and train-pipe and open the latter to the atmosphere and effect a sudden reduction of pressure of from ten to twenty pounds in the train-pipe. The effect of this sudden diminution of pressure in the train-pipe is immediately manifested at the triple-valve mechanism on the first car, causing the valve-piston 29 to be moved by the higher pressure of auxiliary-reservoir air quickly to its full outward position, thus moving the main valve 22 and opening the main port *c*, so that the air-pressure contained in the valve-chamber C may exhaust freely into the brake-cylinder. The supply of air from auxiliary reservoir to the valve-chamber is conducted through the restricted or small passage B. Hence when the main port *c* is fully opened and the air in valve-chamber C escapes through the larger passage thus provided, the pressure in said valve-chamber is quickly reduced below that in the piston-chamber D on the auxiliary-reservoir side, notwithstanding the fact that both the valve-chamber and the piston-chamber on said side receive air from the same source—*i. e.*, the auxiliary reservoir. The exhaustion of pressure from the valve-chamber C or the great reduction of pressure therein following the sudden opening of the main port *c* brings said air pressure below that existing in the train-pipe, whereupon the check-valve 26 will be immediately unseated by said train-pipe pressure, and train-pipe air will then pass directly into the brake-cylinder J, thus effecting the quick application of the brakes and also further reduction of pressure in the train-pipe that will be sufficient to accelerate the action of the valve mechanism on the cars following. The piston 29 will in the meantime be held to its outward position by the relatively higher air-pressure from the auxiliary reservoir, which is delivered through the large passage A, while the transmission of auxiliary-reservoir air to the brake-cylinder is retarded by having to pass through the relatively smaller passage B. Thus a considerable volume of train-pipe air at lower pressure—say fifty to sixty pounds—will flow into the brake-cylinder, notwithstanding the admission of the auxiliary-reservoir air under a higher pressure, because the flow of auxiliary-reservoir air is so retarded by the smaller passage B that an appreciable period of time is required to raise the pressure in the brake-cylinder so that it and that in the auxiliary reservoir will be equal, and it is during this interval and before the pressure in the brake-cylinder is raised to equal that in the train-pipe that the air from the latter is free to enter the brake-cylinder. It will thus be seen that the sudden uncovering of the main port *c*, leading to the brake-cylinder, opens communication both between the train-pipe and brake-cylinder and also between the auxiliary reservoir and the brake-cylinder. As soon as the pressure above the check-valve, caused by the auxiliary-reservoir air plus the pressure of the spring 27, exceeds the pressure exerted by the train-pipe air on the other side the check-valve will close and the further ingress of train-pipe air to the brake-cylinder will

be cut off, while the auxiliary-reservoir air will continue to flow, thus augmenting the pressure in the brake-cylinder. This valve mechanism belongs to the class of air-brake valves known as "triple valves," of which there are numerous examples, differing somewhat in construction and embodying variations and modifications in the form and arrangement of parts; but all of them, however specially constructed, contemplate a valve structure having suitable connections for the train-pipe, the auxiliary reservoir, and the brake-cylinder, and they are provided with passages or ports leading, first, from the train-pipe to the auxiliary reservoir; second, from the said reservoir to the brake-cylinder, and, third, from the brake-cylinder to the atmosphere. Hence the name "triple valves."

An examination of the particular embodiment of the present invention will disclose the fact that it is a triple valve *per se* without auxiliary or supplemental valve devices, and, further, that its conversion into a "quick-action" valve and its greater capacity for action over previous forms of triple valves is due to means here employed for transmitting train-pipe air direct to the brake-cylinder through the triple-valve chamber C and through the port *c* of the triple main valve, and at the same time retarding or restricting the flow of auxiliary-reservoir air to the said main port as compared with the more open or free delivery of train-pipe air to said main port. It will also be seen that a single valve 22, the main valve of the triple valve proper, here performs the office of opening a port *c* to the brake-cylinder, through which port both the train-pipe and the auxiliary-reservoir airs pass in the quick application of the brakes for emergency stops.

In my application for letters patent filed September 30, 1889, serial No. 325,474, I have shown and described a valve for automatic air-brakes of the same type as that which constitutes the subject-matter of the present specification. In my said earlier application the fundamental features of the invention have been claimed. The present specification therefore relates to certain improvements in the construction of said valves.

Having thus described my invention, what I claim as new, and desire to secure by letters patent, is—

1. A triple valve for automatic air-brakes, having, in combination, a port *c*, leading to the brake-cylinder, a main valve 22, which closes and opens said port, a valve to release the air from the brake-cylinder, a piston actuated by air-pressure, and a stem having one end suitably connected with the piston and which passes loosely through the main valve and also through the said port leading to the brake-cylinder and imparts movement to the said release-valve.

2. A triple valve for automatic air-brakes, having, in combination, a port *c*, leading to the brake-cylinder, a main valve 22, which closes and opens said port, a valve to release the air from the brake-cylinder, a piston actuated by air-pressure, a stem having one end suitably connected with the piston and which passes loosely through the main valve and also through the said port leading to the brake-cylinder and imparts movement to the said release-valve, and a stop-shoulder on the said stem between the main valve and release-valve.

1319 & 1320

3. A triple valve for automatic air-brakes, having, in combination a port c, leading to the brake-cylinder, a piston actuated by air pressure, a stem having one end suitably connected with the piston constructed to act as a graduating-valve, a main valve 22, loose on said stem and which rides or floats lengthwise thereof and is wholly supported thereby and opens and closes the said port leading to the brake-cylinder, and a stop-shoulder on the stem to come in contact with the said main valve, whereby when the brakes are being applied by the graduating-valve the main valve remains immovable and the stop-shoulder coming in contact with it arrests the movement of the said piston.

4. A triple valve for automatic air-brakes, having, in combination a passage from the train-pipe, a passage from the auxiliary reservoir which is smaller or more restricted than said train-pipe passage, a main port co-acting with both of said passages and communicating between them and the brake-cylinder, a piston actuated by air pressure, a stem having one end suitably connected with the piston and a valve loose on said stem and which rides or floats lengthwise thereof and is wholly supported thereby and opens and closes the said main port communicating to the brake cylinder.

5. A triple valve for automatic air-brakes, having, in combination a valve to release the air from the brake-cylinder, a piston actuated by air-pressure, a main port c, leading to the brake cylinder and located between the said release-valve and piston, a stem having one end suitably connected with the piston and which passes through said port and imparts movement to the said release-valve, and said stem provided with a passage having a lateral port for the flow of a small volume of air to apply the brakes by graduation, and a main valve 22, which is free to ride or float lengthwise on said stem and opens and closes the said lateral graduation-port and which also opens and closes the main port leading to the brake-cylinder.

6. A triple valve for automatic air-brakes, having, in combination a port communicating with the brake-cylinder from both the auxiliary reservoir and the train-pipe, means for restricting the flow to the said port of auxiliary-reservoir air when applying the brake for an emergency stop as compared with the flow of train-pipe air, a piston actuated by air-pressure, a stem having one end suitably connected with the piston and which is provided with a small passage for the flow of auxiliary-reservoir air to apply the brake by graduation, and a main valve 22, which rides or floats loosely on said stem and is wholly supported thereby and opens and closes the said port communicating with the brake-cylinder and also controls the said small graduation-passage.

In testimony whereof I affix my signature in the presence of two witnesses.

UNITED STATES PATENT OFFICE.

GEORGE A. BOYDEN, of Baltimore, Maryland, assignor to the Boyden Brake Company of Baltimore City, of Maryland.

Valve for Automatic Air-brakes.

Specification forming part of Letters Patent No. 481,136, dated August 16, 1892. Application filed February 12, 1892. Serial No. 421,237. (No model.)

To all whom it may concern:

Be it known that I, George A. Boyden, a citizen of the United States, residing at Baltimore, in the State of Maryland, have invented certain new and useful improvements in valves for automatic air-brakes, of which the following is a specification.

This invention relates to a new and improved valve for automatic air-brakes of that class which are called "triple valves." One object of the invention is to provide for admitting air-pressure to the brake-cylinder from both the train-pipe and the auxiliary reservoir by the ordinary slide-valve of the triple valve to produce a quick application of the brakes, and thereby avoid employing an auxiliary valve.

Another object is to provide triple valves which employ slide-valves with new and improved means for graduating without the complication of additional movable parts to the slide-valve and piston, which said means shall be controlled by slight variations of pressure in the train-pipe, so that any desired degree of brake-pressure may be applied to the wheels of the cars.

Since the air-brake triple valve proper has been developed to the slide-valve form, as shown in United States patent to Westinghouse, No. 168,359, dated October 6, 1875, two additional or "auxiliary" valves have been arranged to co-operate with the said triple valve to perform additional functions in braking—to wit, that of "graduating" the brakes—a function that is illustrated in United States patent to Westinghouse, No. 220,556, dated October 14, 1879, and that of "quick action," which is to apply the brakes with greater rapidity and power by partially exhausting the train-pipe of air and discharging said air, together with auxiliary-reservoir air, into the brake-cylinders, a function that is illustrated in United States patent to Westinghouse, No. 360,070, dated March 29, 1887.

Heretofore in triple valves which employ slide-valves where the endeavor has been made to provide for quick action in emergency stop the auxiliary-reservoir air alone has passed to the brake-cylinder by the opening of the slide-valve, while the train-pipe air has passed to said cylinder by a different valve—that is, the auxiliary valve last referred to.

The first part of my present invention consists, broadly, in the combination, with a triple valve having a piston and slide-valve which is moved one way by auxiliary-reservoir-air pressure, of

means whereby both train-pipe air and auxiliary-reservoir air may be admitted by the same slide-valve to the brake-cylinder for applying the brakes. By this part of my invention the air from the train-pipe may be admitted directly to the brake-cylinder without interfering with the usual operation or functions of the triple valve, and also without the aid of the auxiliary valve heretofore required for the purpose. My invention enables the triple valve alone to produce what is called "quick action" in emergency applications.

The second part of my invention consists in the combination, with a slide-valve which is operated by the movement of a piston, of a passage for auxiliary-reservoir air to preliminarily apply the brakes gradually or partially with any degree of pressure, the inlet to which passage is controlled by the said piston and the exit from the passage is controlled by the slide-valve. By this part of my invention the "graduation" or partial application of the brakes may be effected without the use of an auxiliary valve, and also without liability when closing the graduating-passage which admits auxiliary-reservoir air to the brake-cylinder to move the slide-valve to the "release position," where the brake-cylinder air will exhaust to the atmosphere, and thus unintentionally release the brakes at a time when it is desired to keep them applied.

The invention is illustrated in the accompanying drawings.

(Here follow diagrams marked pp. 1322, 1324, 1326, 1328 & 1330.)

Figure 1 shows an auxiliary reservoir and brake-cylinder in section and a side view of my improved valve and illustrates one way of attaching the said valve. Fig. 2 is a longitudinal section of the improved valve on the line 2 2, showing all the parts, the slide-valve being in the release position. Fig. 3 is a view of the valve-case at that end which is to be secured to the auxiliary reservoir.

Fig. 4 is a longitudinal section of the valve-case on the line 1332 4 4, which is transverse to that on which Fig. 2 is taken and shows the slide-valve seat. Fig. 5 is a cross-section of the valve-case on the line 5 5. Figs. 6, 7, and 8 are views of the slide-valve. Fig. 9 is a view of the piston, the parts which are rigidly connected with it, and the slide-valve, these composing all the parts which are removable from the body of the case for inspection or cleaning. Fig. 10 is an end view of the partition, slide-valve, and piston. Fig. 11 is a section of the complete valve, showing the piston, slide-valve, and check-valve in the emergency-stop position and while the train-pipe air is flowing to the brake-cylinder. Fig. 12 shows a modification in the structural features of the valve-case and in the organization of the parts, but which employs a slide-valve, as in Fig. 2, and has the same mode of operation as the structure there shown. Fig. 13 shows a cross-section of the valve-chamber seen in Fig. 12 on the line 13 13.

The valve-case 5 is to be connected with the auxiliary reservoir or brake-cylinder, as desired, and secured at any suitable place, so that the passages A to the piston-chamber will communicate with

said reservoir and the passage g' from the valve-chamber will communicate with the brake-cylinder. The nozzle 1 is to be connected with the train-pipe, the exhaust-passage G opens to the atmosphere, and the port i in the valve-chamber is the inner end of this exhaust-passage. The valve-case is provided with an ordinary drip-chamber E to receive the water of condensation, and the water may be drawn therefrom by removing a plug 4. The piston-chamber D, valve-chamber C, piston 29 and attached stem g^2 , the slide-valve H, and spring n , which holds the said valve to its seat, are all relatively arranged substantially like those parts in triple valves heretofore made.

The first part of my invention will now be described.

Referring to the drawings Figs. 2 to 9, one side of the piston 29 is provided with a conical projection or face a , which stops against the end of the bushing b of the valve-chamber C. Extending from this side of the piston is the stem g^2 , which projects into the valve-chamber and moves the slide-valve H. A passage F leads from the train-pipe nozzle to the piston 29, and a continuation F' of this passage leads around the piston-chamber D to the far or right-hand end of the said bushing b . A check-valve 26 is located at some suitable point in this passage and a spring 27 holds it normally to its seat 28. A cap-nut 30 serves as a guide for the stem of the check-valve and also confines it. By removing the cap-nut the check-valve may be withdrawn. The piston-stem g^2 carries a head or partition 9, which fits snugly and moves in the valve-chamber bushing b . In Figs. 2, 8, 9, and 10 this partition is shown located on the end of the stem and acts on the end of the slide-valve when the piston moves outward or to the left. When the piston has completed its full stroke to the left—the emergency-stop position, (see Fig. 10.)—the brake-cylinder port c is wide open and the partition 9 serves to retard or restrict the auxiliary-reservoir air in its transmission to the said port. At the moment the brakes are being applied for an emergency stop the partition has the effect to confine on the auxiliary-reservoir side of the piston a greater pressure than that of the air passing through the brake-cylinder port, as herein-after explained. A restricted or small passage B through the partition 9 serves as an air communication between opposite sides thereof. A feeding-groove a' is formed on the conical face of the piston 29. Passages A are formed in the case around the valve-chamber and constitute a direct communication between the auxiliary reservoir and the piston-chamber D and without passing through the valve-chamber C. In the present instance six passages A are shown, the combined area or capacity of which affords an ample supply of auxiliary-reservoir air for emergency applications. If desired, the number of these passages may be varied. One passage will serve the purpose as well if it is large enough. The cap 3 is secured to the valve-body 5 by suitable bolts. By taking off this cap all the movable parts of the valve, including those which produce quick action, may be withdrawn for inspection or repair. The communication between the train-pipe nozzle 1 and the auxiliary reservoir for charging the same with compressed air is

by way of the passages F F', restricted passage B, valve-chamber C, groove a' , piston-chamber D, and the passages A. Communication between the train-pipe nozzle 1 and the brake-cylinder direct to produce quick action in emergency stops is by way of the passage F F', slide-valve port c , and passage g' . Communication between the auxiliary reservoir and brake-cylinder for ordinary full application of the brakes, also for quick action, (not including graduating however,) is by way of the passages A, piston-chamber D, valve-chamber C, restricted passage B, slide-valve port c , and passage g' . Communication between the brake-cylinder and atmosphere to release the brakes is by way of the passage g' , slide-valve port c , the cavity j in the slide-valve, the port i in the seat of the slide-valve, and the exhaust-passage G.

It will be seen by the foregoing that a novel feature of this part of my invention is that one and the same slide-valve H here serves three purposes, to wit: First, quick action in applying the brakes for emergency stops by the passage of train-pipe air to the brake-cylinder in conjunction with auxiliary-reservoir air; second, ordinary full application of the brakes by the passage of auxiliary-reservoir air alone to the brake-cylinder, and, third, the release of the brakes.

The second part of the invention—to wit, the improved means for gradually applying the brakes—will now be described.

1333 A passage e to admit auxiliary-reservoir air to produce graduated application of the brakes is in the valve-case and leads from the piston-chamber D to the seat of the slide-valve where its exit-port e^2 opens through the bushing b to said seat. The slide-valve H is provided with a cavity j , and its face has two openings in the form of cross-slots $j' j^2$, one opening being at each end of said cavity, which serve to complete the communication between the exit-port of said graduating-passage and the slide-valve port c , leading to the brake-cylinder. The piston 29 opens and closes the inlet-port e' of the graduating-passage, so that auxiliary-reservoir air may enter the said passage and flow to the brake-cylinder as soon as the opening j^2 of the slide-valve cavity registers with the exit-port e^2 , and thereby establishes communication between the said passage e and the main port c . The passage from the auxiliary reservoir to the brake-cylinder for graduating is as follows: by way of the passage A, piston-chamber D, passage e , cavity j in the slide-valve, and passage g' . The piston 29 is provided on the train-pipe side with a yielding stem or knob t , which comes in contact with a plate u to check or retard the movement of the piston when graduating. The knob-stem t fits telescopically through the piston and into its stem g^2 , and a spiral spring v serves to keep the knob-stem projected with a certain degree of tension.

The operation of my improved valve is as follows: To charge the auxiliary reservoir, the air from the train-pipe entering at the nozzle 1 passes through the passage F to the piston 29 and moves it to the position shown in Fig. 2, where the release-port is open. The air continuing, opens the check-valve 26 to the passage F' and passes to the partition 9, then through the small passage B to the valve

chamber C, through groove *a'* to the piston-chamber D, and then through the passages A to the auxiliary reservoir. The brakes may be applied fully in two ways: first, by the auxiliary-reservoir pressure alone, and, second, by the auxiliary-reservoir pressure in conjunction with the train-pipe pressure. The first mode may be used when an ordinary gradual stop is required, such as at a station. The second mode produces quick action and is used when an emergency stop is required, such as upon the occurrence of an accident. To apply the brakes fully by auxiliary-reservoir-air pressure alone, the engineer's valve is turned to gradually and continuously discharge air from the train-pipe. This particular manner of discharging air at the engineer's valve will slowly move the piston 29 and slide-valve H until they reach their full stroke to the left and open port *c*; but in making this slow movement the air from the train-pipe will not pass to the brake-cylinder, because there will be time sufficient for auxiliary-reservoir air to pass the restricted passage B and accumulate in the passage *g'* and in the brake-cylinder and by accumulating there prevent the pressure in the valve-chamber on the right-hand side of the partition and in the passage F' from becoming reduced to such degree as will allow the diminishing train-pipe pressure to unseat the check-valve 26, and thereby prevent the passage of the train-pipe air to the brake-cylinder. Thus it will be seen that a gradual and continuous reduction of train-pipe pressure at the engineer's valve, as stated, will afford time for the air-pressure, which has been disturbed or slightly unbalanced in the several chambers and passages of the valve-case, to become readjusted and equalized and thereby prevent such a diminution of pressure on the valve-chamber side of the check-valve 26 as will cause the latter to unseat. In this way the parts of the valve device which are comprised in what I have termed the "first part" of this invention accomplish one of the ordinary functions of triple valves in applying the brakes fully by auxiliary-reservoir-air pressure alone. To apply the brakes fully by quick action for an emergency stop, the train-pipe pressure is suddenly reduced by discharging at the engineer's valve, say, about twenty pounds, which quickly moves the piston 29 and its attached parts their full stroke to the left. This will move the slide-valve H and open the port *c* and close the release-port *i*. By thus suddenly and fully opening the main port *c* a passage is opened from the train-pipe direct to the brake-cylinder, through which air from the train-pipe will pass. This passage is as follows: From the nozzle 1 through the passage F, the check-valve 26, and passage F', and as the slide-valve H has been quickly moved to its full open position the condition of pressure will be favorable, as hereinafter explained, and the air will pass through this valve-port *c* directly from the train-pipe to the brake-cylinder. This operation of the valve is due to the coaction of three momentary differential pressures immediately after the piston 29 has suddenly moved its full stroke to the left. These pressures approximately are seventy pounds from the auxiliary reservoir acting on the piston 29 and holding it to the extreme end of its stroke; fifty pounds in the train-pipe and at op-

posite side of piston, due to the twenty pounds reduction by the aforesaid discharge at the engineer's valve, and, say, five pounds in the valve-chamber (see Fig. 11) on the right-hand side of the partition in the passage F' and on one side of the check-valve 26, due to the sudden air-discharge therefrom through the wide-open port *c* and to the fact that the auxiliary-reservoir-air supply thereto is restricted through the small passage B. In this operation the fifty pounds pressure on the train-pipe side of the check-valve unseats the latter and passes through the passage F', the open port *c*, and passage *g'* into the brake-cylinder, thereby performing two
 1334 functions in quick action—to wit, partially emptying the train-pipe, which quickens the action of the triple valve on the brakes of the following car, and partially charging the brake-cylinder with the train-pipe air, which augments the pressure applied to the wheels of the car. After the air-pressures in the train-pipe and brake-cylinder have equalized auxiliary-reservoir air will continue to pass through the said open port *c* to the brake-cylinder, coming by way of the passages A, piston-chamber D, valve-chamber C, and restricted passage B, until there is an equalization of air-pressure in both said reservoir and cylinder. It will thus be seen that the piston which actuates the slide-valve is moved in one direction by auxiliary-reservoir pressure and that air may be passed through the said slide-valve port *c* to the brake-cylinder from both the train-pipe and the auxiliary reservoir to produce quick action for an emergency application of the brakes, and thereby I avoid the employment of an auxiliary valve. The quick-action function does not follow when the port *c* leading to the brake-cylinder is opened slowly and gradually, because then the pressure adjoining the partition 9 on the right-hand side is not reduced materially below the train-pipe pressure. On the other hand, the quick action will follow when said port *c* is opened suddenly and fully, because then the pressure at said location will be reduced sufficiently below the train-pipe pressure for the latter to unseat the check-valve and pass through the right-hand end of the triple-valve chamber to the brake-cylinder. The sudden movement of the slide-valve uncovers the main port *c*, leading to the brake-cylinder; but the flow of the higher-pressure air from the auxiliary reservoir into the brake-cylinder is retarded by being compelled to traverse a relatively small passage (in the present instance at the partition) while the flow of the lower-pressure train-pipe air into the brake-cylinder is facilitated by permitting it to traverse a much larger passage. Therefore the same valve-port *c* allows a considerable volume of train-pipe air to flow into the brake-cylinder, notwithstanding the admission through the same port at the same time of the auxiliary-reservoir air under a higher pressure. To release the brakes, a sufficient amount of air is admitted from the main reservoir, which is on the locomotive, to the train-pipe to overcome the resistance of the auxiliary-reservoir pressure and the friction of the slide-valve H and move the piston 29 and said valve toward the right hand to the position shown in Fig. 2, and thereby establish communication between the brake-cylinder and atmosphere by way of the passage

g' , cavity j , release-port i , and exhaust G. In addition to the said quick-action result obtained by the construction and combination of parts comprising the first part of my invention another useful result or advantage is gained, to wit: Should the piston and slide-valve "stick" by reason of the accumulation of dirt or of gum formed by the oil and fail to move forward when compressed air is first applied to the brake-pipe before the train starts out, then under such circumstances the brakes would be applied by the train-pipe air passing directly to the brake-cylinder, and thereby indicate to the trainmen the defective condition of the brakes. To partially apply the brakes by graduation, either to check the speed of the train or to gradually stop, the train-pipe pressure is reduced slightly but sufficiently to move the piston and slide-valve H to a position that will put the second opening j^2 of the cavity of the valve in connection with the exit-port e^2 of the graduating-passage and cause the piston to open the inlet-port e' of said passage to the auxiliary-reservoir air. The train-pipe pressure must not be reduced enough to enable the greater auxiliary reservoir pressure acting on the piston to overcome the tension of the spring v . This movement of the piston and slide-valve to the left allows auxiliary-reservoir air to continue passing through the graduating-passage e to the brake-cylinder until the pressure on the auxiliary-reservoir side of the piston has been reduced below that which is on its train-pipe side, whereupon the train-pipe pressure will move the piston 29 (but not the slide-valve) partly back to the right until the piston-ring packing closes the inlet-port e' , which by cutting off the flow of auxiliary-reservoir air will so retard the back movement of the piston that the shoulder g^3 of the stem will abut the slide-valve easily. There is sufficient play between the shoulder g^3 and the partition 9 to permit a movement of the piston independent of any movement of the slide-valve H. When the piston-shoulder g^3 abuts easily, as stated, against the end of the slide-valve, the resistance of the latter will stop the piston with its packing-ring over the said inlet-port e' for the time being and prevent any more air passing through the graduating passage e . An advantage resulting from this graduating operation is that when enough air has been entered into the brake-cylinder to effect the desired partial application of the brakes the flow of air through the graduating-passage e is cut off by the piston packing-ring, which prevents the slide-valve being abutted as severely as in devices heretofore employed. Consequently in thus first cutting off the said air-flow there is no liability to move the slide-valve to the release position and unintentionally release the brakes. Thus the graduation is effected by the slide-valve and without the use of an auxiliary valve. The restricted passage B for the supply of auxiliary-reservoir air when applying the brakes for emergency stops is shown in Figs. 2 and 10, for the purpose of clear illustration, as a small hole through the partition 9; but a special hole or passage is not necessary, as the partition 9 may fit the bushing b loosely enough to leave a small space between the rim 9^a of the partition and the wall of the bushing. Such looseness of fit or the space formed thereby may constitute

the restricted passage, and I have used valves constructed in this manner. The restricted passage may also be formed as a distinct channel in the case, as at B' in Fig. 11 or as at B^2 in 12. The partition may be located differently from what is shown in Figs. 2 and 11. It is obvious it may be anywhere on the stem g^2 , so that it is not withdrawn from the bushing when the piston completes its stroke to the left. It may also be stated that the piston itself may under certain conditions be made to serve as a partition. This is illustrated in Fig. 12.

Fig. 12 illustrates a modification in the construction and arrangement of the parts of a valve embodying my invention. This form of valve, although differently organized from that shown in Figs. 2 to 11, inclusive, has the same parts or their equivalents and has the same mode of operation and produces the same result. The valve shown in Fig. 12 differs from that shown in the other figures chiefly in that the slide-valve of Fig. 12 is located on the train-pipe side of the actuating piston, whereas in the other figures it is located on the auxiliary-reservoir side of said piston. Referring to Fig. 12, the valve case 5 is connected with the auxiliary reservoir J and a communication A' opens at one end of said reservoir direct to one side of the piston 29^a and without passing through the valve-chamber C' . The passage g' leads from the valve-chamber to the brake-cylinder I through a pipe m . The nozzle 1 connects with the train-pipe, the exhaust-passage G opens to the atmosphere, and the port i through the valve-seat connects with said exhaust-passage. The piston 29^a , stem g^2 , head d , slide-valve $11'$, and spring u are all substantially like the same parts in Fig. 2. The check-valve 26 is located in the train-pipe passage F, as in the other figures. The relative positions of the piston and slide-valve in the valve-case are reversed in Fig. 12 from what they are in Fig. 2, and a feed-groove a^2 is in the bushing of the piston-chamber D' . The piston 29^a in this modification serves the same functions as the piston 29 in Fig. 2; but it here serves also a function ascribed to the partition 9 in Fig. 2, namely: At the moment when the brakes are being applied for an emergency stop the piston has the effect to confine on its auxiliary-reservoir side a greater pressure than that of the air passing through the brake-cylinder port c . This last function results from the location of the piston on the auxiliary-reservoir side of the slide-valve and the combination therewith of an ample or large passage $F F^2$ for train-pipe air and a restricted or small passage B^2 for the supply of auxiliary-reservoir air when applying the brakes for emergency stops. This restricted passage B^2 has its inlet e^5 in the piston-chamber and its exit in an annular groove q around the valve-chamber. In this instance the passage from the train-pipe nozzle for charging the auxiliary reservoir and to the brake-cylinder to produce quick action in emergency stops is through the valve-chamber C' and past the back of the slide-valve $11'$. The piston-stem g^2 is tubular and on the train-pipe side has a yielding stem t' , which fits and moves telescopically into the piston-stem, and a spiral spring v' keeps the yielding stem normally projected. The end of the yielding stem t' comes in contact with a plate u' and retards the move-

ment of the piston when graduating. The slide-valve I I' in this case has two cavities *k* *o* and a central face *p* between them. One cavity *k* connects the brake-cylinder passage *g'* with the release-port *i* and the other cavity *o* connects with a port *e'* in the slide-valve seat, which port communicates with the restricted passage B² by way of the annular groove *q* in the case, which groove is covered by the bushing *b'*. To charge the auxiliary reservoir, Fig. 13, train-pipe air passes through passage F F², valve-chamber C, piston-chamber D', and feed-groove *a*². To apply the brakes fully by auxiliary-reservoir pressure alone, the piston 29^a moves slowly to the left and then air passes from the auxiliary reservoir J through the port *e*, restricted passage B², annular groove *q*, port *e'*, in the slide-valve seat, and passage *g'* to the brake-cylinder. This will continue until the full power of the auxiliary-reservoir air is exerted in the brake-cylinder. To apply the brakes fully by quick action for an emergency stop, the piston 29^a must be moved quickly to the left, and thus suddenly open the main port *c*. The air pressure in the valve-chamber C' between the piston and the check-valve will at once discharge through the passage *g'* into the brake-cylinder, which will reduce the pressure at said location below the train-pipe pressure. Thereupon the check-valve 26 will unseat and train-pipe air will pass freely to the brake-cylinder by way of the passage F F² back of the slide-valve II' through the port *c* and passage *g'*. At the same time the auxiliary-reservoir air at higher pressure than the said train-pipe air will also pass to the brake-cylinder through the restricted or small passage B², annular groove *q*, port *e'*, port *c*, and passage *g'*. Thus in applying for emergency air passes to the brake-cylinder through the same port from both the train-pipe and the auxiliary reservoir. To release the brakes, the piston 29^a is moved toward the right hand to the position shown in Fig. 12, where the cavity *k* in the slide-valve connects the passage *g'* with the release-port *i*, and thus establishes communication from the brake-cylinder to the atmosphere. To partially apply the brakes by graduation, the piston 29^a will be moved from the position shown in Fig. 12 toward the left far enough to open the inlet-port *e*⁵ to the auxiliary-reservoir air, and also put the cavity *o* of the slide-valve in connection with the port *e'*, and also the passage *g'*, leading to the brake-cylinder. In graduation the piston 29^a is kept in this position but a moment, and then moves toward the right hand and covers the inlet-port *e*⁵, and thereby stops the flow of auxiliary-reservoir air to the brake-cylinder. It will thus be seen the passage B² in this modification serves to transmit auxiliary-reservoir air to the brake-cylinder in a restricted manner when applying for emergency stops, and also to transmit such air when graduating.

It will be seen that no auxiliary valve is employed and that a single slide-valve controls the compressed air in the several actions which the apparatus is designed to perform—to wit, applying the brakes by the full power of auxiliary-reservoir pressure alone, releasing the brakes, applying the brakes on the so-called "quick-action" plan—i. e. by train-pipe pressure in conjunction with auxiliary-reser-

voir pressure—and partially or wholly applying the brakes by graduating. It will also be seen that while I have provided for the said quick-action result to be effected by a single slide-valve alone and without an auxiliary valve, yet this feature of my invention may be worked or employed in connection with graduating devices of different structure from that here shown.

It is to be understood that various of the structural features here shown or described and the form and location of the ports and passages may be changed or varied without departing from my invention.

Having thus described my invention, what I claim as new, and desire to secure by letters patent, is—

1. The combination, in valve mechanism for automatic air-brakes, of a port through which air passes to the brake-cylinder from both the train-pipe and auxiliary reservoir to produce quick action, a port leading to the atmosphere to exhaust the air from the brake-cylinder, a single slide-valve to control the said ports, and a piston which actuates the slide-valve and is moved in one direction by auxiliary-reservoir pressure and in the opposite direction by train-pipe pressure.

2. The combination, in valve mechanism for automatic air-brakes, of a piston actuated in one direction by auxiliary-reservoir pressure and in the opposite direction by train-pipe pressure, and a single slide-valve controlling the passage of air to the brake-cylinder from both the train-pipe and auxiliary reservoir for an emergency application of the brake.

3. The combination, in valve mechanism for automatic air-brakes, of a piston-chamber, a piston, a valve-chamber having a port through which air passes to the brake-cylinder from both the auxiliary reservoir and train-pipe, a slide-valve controlling said port, and a partition which at the time of applying the brakes separates the auxiliary-reservoir-air pressure that is on the said piston from the pressure in that part of the valve-chamber that is adjacent to the said port.

4. The combination, in valve mechanism for automatic air-brakes, of a valve-chamber, a slide-valve therein controlling the exhaust of air from the brake-cylinder to the atmosphere and also the passage of air to the brake-cylinder from both the train-pipe and the auxiliary reservoir, a piston-chamber, and a piston to actuate the said slide-valve and carrying a partition arranged to retard or restrict the auxiliary-reservoir air in its transmission to the port of the said slide-valve.

5. The combination, in valve mechanism for automatic air-brakes, of a port through which air passes from both the auxiliary reservoir and train-pipe to the brake-cylinder, a port leading to the atmosphere, a passage for auxiliary-reservoir air to pass to said brake-cylinder port, a passage having a greater area than the first-mentioned passage to admit train-pipe air to said brake-cylinder port, a slide-valve to control said ports, and a check-valve located in the said train-pipe passage.

6. The combination, in valve mechanism for automatic air-brakes,

piston-chamber, a piston, a valve-chamber having a port leading to the atmosphere and also a port leading to the brake-cylinder, a slide-valve controlling the said ports, a communication for auxiliary-reservoir air direct to one side of the said piston without passing through the valve-chamber, and a restricted communication for auxiliary-reservoir air to pass to said brake-cylinder port.

7. The combination, in valve mechanism for automatic air-brakes, of a valve-port through which air passes to the brake-cylinder from the auxiliary reservoir and direct from the train-pipe, an exhaust-port, a slide-valve to control the said port, a piston, and communications relatively proportioned to produce on the auxiliary-reservoir side of the piston a greater pressure than that of the said train-pipe passing through the brake-cylinder port.

8. The combination, in valve mechanism for automatic air-brakes, of a slide-valve seat having a port which is in communication with the brake-cylinder, a passage through which train-pipe pressure is transmitted to the said brake-cylinder port when applying the brakes for emergency stops, a passage of more restricted capacity than said train-pipe passage and through which auxiliary-reservoir pressure also is transmitted to the said brake-cylinder port when applying the brakes for emergency stops, and a slide-valve resting on said seat and coacting with said port and controlling the passage to the brake-cylinder of both the train-pipe and auxiliary-reservoir pressure, as set forth.

9. The combination, in valve mechanism for automatic air brakes, of a slide-valve, a piston which actuates the said slide-valve, and a graduating-passage for auxiliary-reservoir pressure to preliminarily apply the brakes, the exit from which passage is controlled by the said slide-valve and the inlet thereto by the said piston and which passage admits auxiliary-reservoir pressure to the brake-cylinder when open at both of said controlled places.

1037 & 1338 10. The combination, in valve mechanism for automatic air-brakes, of a slide-valve seat having a port which is in communication with the brake-cylinder, a passage leading to the said slide-valve seat and through which auxiliary-reservoir pressure is transmitted for graduating the brakes, a passage through which train-pipe pressure is transmitted to the said brake-cylinder port when applying the brakes for emergency stops, a passage of more restricted capacity than said train-pipe passage and through which auxiliary-reservoir pressure also is transmitted to the said brake-cylinder port when applying the brakes for emergency stops, and a slide-valve traversing said seat and controlling the air passing through all three of said passages.

11. The combination, in valve mechanism for automatic air-brakes, of a slide-valve seat having a port which is in communication with the brake-cylinder, a passage leading to the said slide-valve seat and through which auxiliary-reservoir pressure is transmitted for graduating the brakes, a passage through which train-pipe pressure is transmitted to the said brake-cylinder port when applying the brakes for emergency stops, and a single slide-valve traversing

ing the said valve-seat and controlling the said passages, for the purpose set forth.

12. The combination, in valve mechanism for automatic air-brakes, of a slide valve seat having three ports, the first of which is in communication with the brake-cylinder and the second with the atmosphere, a graduating passage leading to the third valve-seat port and through which auxiliary-reservoir air is transmitted to preliminarily apply the brakes, a single slide-valve traversing the said seat and controlling the graduating or preliminary application of the brakes and the release of the same, and a piston to actuate the said slide-valve and having a limited movement independent thereof.

In testimony whereof I affix my signature in the presence of two witnesses.

GEORGE A. BOYDEN.

1339 *Complainants' Testimony in Reply, under Order of Court Made March 29th, 1894.*

United States Circuit Court, District of Maryland.

GEORGE WESTINGHOUSE, JR., <i>et al.</i>	} In Equity. No. 321.
<i>vs.</i>	
BOYDEN POWER BRAKE Co. <i>et al.</i>	

Messrs. Barton & Wilmer, solicitors for defendants, Baltimore, Md.

GENTLEMEN: Please take notice that testimony on behalf of complainants, in reply to defendants' surrebuttal testimony, will be taken at the offices of George H. Christy, No. 110 Diamond street, Pittsburgh, Pa., commencing on Tuesday, May 8th, 1894, at 10.30 o'clock a. m. The testimony will be taken under the 67th rule in equity, and under the order of the court in this behalf.

J. SNOWDEN BELL,
Of Counsel for Complainants.

Pittsburgh, April 27th, 1894.

Due service admitted this 28th day of April, A. D. 1894.

SKIPWITH WILMER,
Solicitor for Defendants.

1340 United States Circuit Court, District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE
AIR BRAKE COMPANY

VS.

BOYDEN POWER BRAKE COMPANY; CHARLES A. BOY-
DEN, President; Charles B. Mann, Secretary, and
William Whitridge, Treasurer.

In Equity.
No. 321.

Depositions of witnesses and other evidence in reply on behalf of complainants in the above-entitled cause, taken under the 67th rule in equity and under the order of the court made March 29th, 1894, pursuant to the foregoing notice, before F. E. Gaither, notary public, as special examiner, at the offices of George H. Christy, Esq., Bakewell law building, Pittsburgh, Pa., commencing on Tuesday, May 8th, 1894, at 10.30 a. m.

Present: *J. Snowden Bell*, Esq., of counsel for complainants;
Charles B. Mann, Esq., on behalf of defendants.

H. H. WESTINGHOUSE, being recalled in reply, deposes and says, in answer to interrogatories propounded to him by *J. Snowden Bell*, Esq., of counsel for complainants, as follows, to wit:

887 Q. Are you the same H. H. Westinghouse who heretofore testified in this cause?

A. I am.

888 Q. Were you present at the works of the Boyden Brake
1341 Company, Biddle and Chester streets, Baltimore, Md., on
April 12th, 1894, during the making of experiments by Mr.
George A. Boyden, with valve devices alleged to have been con-
structed in accordance with patent No. 217,838?

A. I was.

889 Q. Did you upon that occasion examine said valve devices,
or either of them, and observe the experiments with sufficient atten-
tion to understand them?

A. I did.

890 Q. Have you read the testimony of defendants' witnesses, G.
A. Boyden and L. J. Gwin, commencing April 4th, 1894, relatively
to valve devices alleged to have been made in accordance with
patent No. 217,838, and experiments made with said valve devices,
and their testimony as to the same subjects-matter given April 13th,
1894?

A. I have.

891 Q. In his answer to Q. 248, Mr. Boyden, referring to the valve
devices, to which and to experiments with which the testimony of
himself and Mr. Gwin, specified in the last preceding question,
relates, says:

"I made the devices in strict accordance with the patent 217,838,
in order to shut off cavil as to their being made like the devices
shown and described in the said patent."

Please state whether or not you found these valve devices to be
"in strict accordance with the patent 217,838," and if not, in what

particulars you found that the instructions of said patent had been deviated from?

A. I did not find the devices made by Mr. Boyden to be in strict accordance with the instructions of patent 217,838, but, on the contrary, there were important and wide variations in those structures.

Referring to Fig. 1 of the illustration of patent 217,838, the area of piston D is about four and a half times the area of passage A. In the valve devices experimented with by Mr. Boyden, the relative areas of the corresponding piston and passage is about eighteen to one. In the figure of the patent previously referred to, the 1342 area of passage C, as compared with the area of piston D, is about one to forty, and corresponding portions of the devices made — Mr. Boyden have relative areas of about one to eighteen. So far as I can see from the specification, or from an examination of the drawing, there seems to be no good reason why the relative proportions of the several parts as indicated in the drawings of patent 217,838 should have been departed from.

I examined one of the structures made by Mr. Boyden, and found that a considerable leakage passage had been provided past the piston D, and I regard the presence of such a leakage passage as a complete departure from the instructions of the patent, and one that would defeat the intended operation of the device.

892 Q. In view of the instructions of the specification of patent 217,838, and the showing of the drawing of said patent, and also in view of the established practice in the construction of appliances relating to fluid-pressure brake apparatus, please state whether a skilled mechanic, working from patent No. 217,838, would be led to fit up the devices of said patent so that the pistons thereof would fit as tightly in their casings as is compatible with proper operation, or whether he would be instructed or warranted in failing to make the pistons fit their casings, and in providing a considerable leakage passage around them?

A. I have been unable to find anything, in the specification or drawings of the patent in question, that would justify any departure from the usual practice of a skilled mechanic, in making a structure from the said drawings and specification. Whenever a piston is shown in a drawing as fitting a cylinder, a skilled mechanic would unquestionably understand that, in the absence of special instructions to the contrary, the piston was to be fitted to the cylinder as tightly as possible consistent with its free movement in the cylinder, and I find no instructions in the specification stating that a leakage 1343 passage is to be provided past the piston D. I do, however, observe that there are instructions which call for a construction that would require the piston D to be as tightly fitted to its cylinder as is consistent with free movement.

The last paragraph of the first page of patent 217,838 states that: "But should the pressure in the front part of the pipe communicating with A be reduced intentionally or by accident, then, the valve E closing the holes in the piston D, that piston is pressed down by the pressure from B, and the valve F is drawn from its seat, leaving

the orifice C open for the escape of air from the hinder portion of the pipe which communicates with B; and by giving the piston D and valve E a sufficient length of stroke or motion, such that it will drop below the shoulder s, an open passageway will be formed for the escape of fluid pressure from the enlarged space or port s^1 to s^2 , and thence out at C."

From this description it will be seen that unless piston D is tightly fitted to its cylinder, a reduction of pressure in passage A would not effect a movement of piston D, or an opening of passage C, because the leakage passage would permit the flow of air from above the piston D, thereby preventing the making of a sufficient difference of pressure on the opposite sides of piston D to cause a downward movement.

The presence of the holes d in the piston D, and of the valve E for closing these holes when pressure is reduced on the under side of piston D, clearly indicates that these passages were necessary to permit air to flow through the train-pipe, for the purpose of charging and releasing brakes.

Neither the holes nor the valve referred to would have been required, if a leakage passage were intended to be provided past the piston D.

The portion of the specification quoted, which states that the giving of the piston D and valve E a sufficient stroke to drop below the shoulder s, so that open passageway will be formed for the escape of fluid pressure from the enlarged space or port s^1 to port s^2 , and thence out at C, clearly indicates that piston D should be tightly fitted and without a leakage passage; otherwise, 1344 there would have been no need for a provision for an extra length of stroke of piston D.

As heretofore stated, I have found nothing in the specification indicating that a leakage passage should be provided past the piston D, and the foregoing reasons that I have given, prove to me that there are the best of reasons why such leakage passage should not exist in the structures shown in patent No. 217,838.

893 Q. State whether or not, you find any matter, either expressed or implied, in the specification or drawings of patent No. 217,838, which would instruct, warrant, or justify the construction of such an appliance as is shown in Defendants' Exhibit- "Working Drawing, Patent 217,838, on Angle Cock" and "Tracing of Working Drawing, Patent 217,838, on Angle Cock."

A. I find absolutely nothing that describes or indicates a construction of the kind referred to.

894 Q. Defendants' witnesses Boyden and Gwin allege, in their testimony, that the pistons D were made "about" one sixty-fourth of an inch smaller than the bore of the casings in which they worked. Mr. Gwin also states that Mr. Boyden instructed him to make the pistons one sixty-fourth of an inch smaller than the bore of the casings, and that the devices were fitted up under his (Gwin's) orders by a machinist and workman. Do you find any testimony on the part of defendants, and if so, where, that these instructions were strictly complied with, or that either Mr. Boyden or Mr. Gwin

actually knows or states the precise width of the leakage space around the pistons of the valve devices?

A. I do not find any testimony of the kind stated.

895 Q. Assuming this leakage space to have been only one sixty-fourth of an inch between the pistons and the casings, what would be its area and what its capacity for permitting the passage of air without allowing the devices to be operative?

A. Assuming the leakage passage to be of the size named, it would have an area of about one-fifteenth of a square inch, and it would require an opening from the train-pipe to atmosphere
1345 with an area in excess of one-fifteenth of a square inch to insure the downward movement of piston D.

The size of opening in train-pipe that is usually employed for making all graduated applications of the brakes, has an area of about one-twentieth of a square inch.

896 Q. What, then, would be the result of adding, as you say was done, in the valve devices experimented with by Mr. Boyden, a leakage passage having an area of about one-fifteenth of a square inch, to the valve device described and shown in patent 217,838?

A. The result of such addition was to destroy the intended operation of the device of patent 217,838, except when an excessive or unusual reduction of pressure was made in the train-pipe.

897 Q. The record shows that Mr. Boyden was requested by complainants' representatives to make other and further experiments with the valve devices which he used, and that he refused to do so. Please explain why you desired these further experiments to be made, and how far they would have assisted in determining the question of the practical utility of the valve devices in an automatic brake system?

A. I requested Mr. Boyden to make an experiment with devices which he was using for the purpose of ascertaining whether an increase of train-pipe pressure, made at a slow rate, would release the brakes.

I consider this to be an important point for determination, as it frequently happens, in practice, that the restoration of train-pipe pressure for the purpose of releasing brakes is made very slowly.

The operation of the device shown in patent 217,838, requires that the flow of air into the train-pipe for the purpose of releasing the brake shall be at a fairly rapid rate, otherwise there would be no effective pressure to overcome the resistance of piston D and cause the closure of passage C. And if such movement and closure

does not take place, the pressure admitted to the train-pipe
1346 will flow directly to the atmosphere, through passage C without effecting the release of the brakes.

Mr. Boyden was also requested to have new pistons made in accordance with drawings and specification of patent No. 217,838, so that the piston D should fit its cylinder tightly. The object of this request was to determine the operation of the device of the patent in question, when a leakage space was not provided around the piston D.

898 Q. Having in mind the alleged purpose of the experiment

made with these valve devices by Mr. Boyden, to what extent do you consider his reasons for refusing to make the further experiments requested, to be well founded?

A. I do not consider the reasons given by Mr. Boyden for refusing to make further tests, as well founded. It was suggested that the releasing test be made by placing the handle of the engineers' valve in what is known as the running position; in this position communication between the main reservoir and the train-pipe is considerably smaller than when the handle of the engineers' valve is placed in full release position. Mr. Boyden stated that releasing of brakes with the handle in the running position would be a more severe test than the standard brakes of today are subjected to in practice. He is mistaken as to this point, as brakes are very frequently released with the handle in running position, and in many instances, special instructions have been issued that the brakes were to be released entirely through the running-position port. It has also been proposed by a railroad officer having charge of the operation of brakes, to modify the engineers' valve so there would be but one port, and that one the running-position port, for the purpose of releasing brakes.

The tests made by the Master Car Builders' committee for the purpose of determining the practical value of different kinds of triple valves, are much more severe and exacting than the one proposed to Mr. Boyden. The port through which the air flows 1347 for releasing brakes in the tests referred to, is many times smaller than the releasing port of the engineers' valve when the handle is in running position. I do not consider the test of releasing brakes with the handle of the engineers' valve in running position as at all exacting; and I would consider a brake apparatus as entirely impracticable and useless for regular service, if it would not release under the conditions stated, particularly when the valves are clean and in perfect condition, as was presumably the case with the devices with which Mr. Boyden made his experiments.

With respect to the request that experiments be made with pistons fitting the cylinders tightly in the devices of patent 217,838, Mr. Boyden stated that he would not make these experiments, because the ones already experimented with were made in accordance with patent 217,838, and for the reason that they worked as the specification of that patent states they should work, and that they produced the result which the devices of patent 217,838 were invented to produce.

I think Mr. Boyden is entirely wrong in the reasons that he gave for refusing this request. The operation of the devices, as shown at the tests in question, was not at all in accordance with the intended operation as described in the patent. By reference to Mr. Boyden's testimony it will be seen that when the handle of the engineers' valve was placed in service position, and air was discharged for the purpose of applying brakes, there was no movement of the piston D or valve F, and consequently no discharge of train-pipe air to the atmosphere. The specification of the patent distinctly states that when the pressure in the front part of the train-

pipe is reduced it will cause movement of the piston D and the opening of passage C, for the purpose of discharging train-pipe air to the atmosphere.

The only manner in which the movement of piston D could be obtained in the experiments, was by placing the handle of the engineers' valve in a full application position, and completely
1348 exhausting the air from the train-pipe. Nothing whatever in the specification of patent 217,838 calls for such a mode of operation, or for modifications in the structure of the patent that would cause the device to operate in the manner shown in the experiments in question.

I have already referred to the deviations from the directions of the patent, in the devices made by Mr. Boyden, and in view of these facts and the results of the tests as I witnessed them I think Mr. Boyden is fully and entirely wrong in stating his reasons for not making the tests as requested.

899 Q. If I understand your last preceding answer correctly, in the use of the valve devices experimented with by Mr. Boyden, a full application of the brakes was effected, without opening the release passages C of said valve devices. Am I right or not?

A. Your understanding of their mode of operation is correct.

900 Q. Is it or not possible to effect a full application, or any application, of the brakes, under the terms of patent 217,838, and using valve devices made in accordance with the instructions of the specification and drawing of said patent, without opening the release passages C of said valve devices?

A. If the valves are constructed in accordance with the drawing and specification of the patent, it would be impossible to get any application of the brakes without the movement of piston D and the opening of the port C.

901 Q. Is it or not the fact that, in the use of the valve devices employed by Mr. Boyden in his experiments, there were two distinctly different applications of the brakes, to wit, one a full application, in which the valve devices alleged to be in accordance with patent 217,838 were not operative, and another and a quicker application, in which they were operative?

A. There were two distinct modes of operation, which you have correctly described.

902 Q. Is the capacity of the two kinds of application of
1349 the brakes mentioned in the last preceding question, specified or provided for in patent 217,838, or possible under the construction of that patent?

A. No.

903 Q. Was the capacity of two kinds of application of the brakes, one by the ordinary appliances, and another and a quicker application by other appliances, known in the art at the date of the patent No. 217,838?

A. So far as I am aware of, it was not.

904 Q. Taking the valve device as you saw it experimented with, as changed and modified by Mr. Boyden in the particulars you have stated, and in view of the results produced by Mr. Boyden, what is

your opinion as to the practical merit or value of said valve device for actual use in controlling freight trains on railroads?

A. I agree with the opinion expressed by Mr. Boyden in answer to X Q. 348, that the device, as he used it, would not be acceptable to railroad officials for practical use.

905 Q. To what extent, if at all, would your opinion be modified if the valve device was constructed in strict accordance with patent No. 217,838, instead of deviating therefrom, as used by Mr. Boyden, in the particulars you have specified?

A. Not in any respect.

906 Q. Mr. Boyden admits, in answer to X Q. 305, that it is the fact that long prior to the institution of this suit, he, himself, recognized the obvious practical inoperativeness of the device of patent 217,838. To what extent do you concur in Mr. Boyden's recognition of the obvious practical inoperativeness of this device?

A. I fully concur with him.

Adjourned to meet on Wednesday, May 9th, 1894, at 10 a. m.

WEDNESDAY, May 9th, 1894.

1350

Met pursuant to adjournment at 10 a. m.

Present: Counsel as before.

Cross-examination by CHARLES B. MANN, Esq., on behalf of defendants:

907 X Q. State whether your testimony given yesterday relative to the operation of the device of patent No. 217,838 is based on theory and reasoning, or on the demonstration of actual tests made by you?

A. My testimony was based upon a careful examination of the specification and drawings of the patent, and upon the experiments that I witnessed that were made by Mr. Boyden.

908 X Q. Then, you have not made and tested valve devices constructed in accordance with patent 217,838?

A. I have made and tested valves made in accordance with patent 217,838.

909 X Q. State whether or not you understand patent 217,838 has for its object to provide valve devices, by use of which the material advantage could be effected of having all the brakes of the train applied or brought into action simultaneously, or as nearly so as possibly?

A. In a general way, I understand the object of the patent in question to be as stated in the question.

910 X Q. In your answer to Q. 891 you state that there are important and wide variations between Fig. 1 of the drawing of patent 217,838, and the valve devices made and tested by Mr. Boyden. You say, in substance, first, that Mr. Boyden's valves have passages A with area relatively smaller than the pistons D, as compared with the said patent drawing; second, that the area of passages C are relatively larger than the area of the pistons D, as compared with said patent drawing, and, third, that the pistons D were made

smaller than the casings to provide a leakage passage. I now ask you if the devices made by Mr. Boyden were substantially like Fig. 1 of the drawings of the patent, with the exception of your three alleged variations?

1351 A. The devices made by Mr. Boyden that I saw had the general form and appearance of the structure shown in Fig. 1 of the patent. I made personal examination of only one of the devices, and it seemed to be made in accordance with the blue print which is one of the defendants' exhibits.

911 X Q. As to the first of the three variations you mention, do you not think that the purpose of Mr. Boyden could have been endeavor to preserve the general proportions of the device as they appear in Fig. 1 of the patent, and at the same time have the passage of a size that would fit the hose coupling on his test-rack?

Objected to as incompetent, it being obviously impossible for the witness to divine what Mr. Boyden's purpose was in deviating from the patent.

Counsel for defendants replies that the question has reference to a variation which the witness has referred to as existing between the valves as made by Mr. Boyden and Fig. 1, as in the patent. The question does not ask the witness if he could divine what Mr. Boyden's purpose was, but simply inquires, if a certain stated purpose could not, in the opinion of the witness, have been the purpose that actuated Mr. Boyden in changing the proportions of the passage A and piston D.

A. It is impossible for me to say what Mr. Boyden's object was in departing from the instructions of the specification and drawing of patent No. 217,838 in the manner that he did.

With reference to the particular variation asked about, I cannot see that making the piston D relatively larger than the passage A as compared with the proportions shown on the drawing of the patent, in any way facilitated or affected the fitting of his device to the hose couplings that he used, for the reason that the
1352 cylinder in which the piston D moves is considerably above the hose coupling and not at all limited by, that portion of the structure which screws into the hose coupling.

912 X Q. As to the second of the three variations you mention, do you not think it quite reasonable that the purpose Mr. Boyden could have in making the escape passage C relatively larger than it is shown in the patent drawing, was on account of the larger-size train-pipe that is now used with air brakes, as compared with the size of the train-pipe that was used in the year 1879, his test-rack being equipped with the larger-size pipe?

A. As previously stated I cannot know what purpose Mr. Boyden had in making the variations in the structure of patent 217,838 that he did make on the devices that I saw tested in his works at Baltimore; it, however, seems entirely unreasonable to me that he should have carried out his experiments with devices essentially differing from the kind described in the patent, having widely varying proportions as compared with those shown in the patent, and testing

these devices upon a rack with a train-pipe of a size that was not known or used in regular air-brake practice at the time of the invention of the device in question, and for nearly eight years subsequent to its issue. The size of train-pipe that was in use at the time the device in patent 217,838 was invented, was three-quarters of an inch in diameter, and each car had a length of about sixty feet; the size of train-pipe that Mr. Boyden used in his test is of inch and a quarter diameter, and each car has a length of about forty feet, and this larger pipe came into use about the year 1887. The reasonableness of the variation referred to that was made by Mr. Boyden, does not appear to me, as the increase of the capacity of the train-pipe was about doubled as compared with what was in general use in 1879, while the increase in the size of opening used in the devices tested by Mr. Boyden, was about in the proportion of ten to one.

913 X Q. As to the third of the variations you mention, 1353 do you not think it quite reasonable that the purpose Mr. Boyden could have in making the pistons D one-sixty-fourth of an inch smaller than the casings in which they moved, was to avoid the liability of the pistons' sticking, due to grit or sediment, of which more or less is usually contained in train-pipes?

A. I regard the presumption stated as entirely unreasonable, because it is not at all likely that the modification described would remedy the supposed objection. I cannot conceive that it is reasonable to make any modification in a structure that will destroy its intended operation, and there are much better methods of overcoming the suggested trouble than the making of a loose-fitting piston.

914 X Q. In the construction of appliances relating to air-brake apparatus, where it is desired to have a piston fit a cylinder so as to prevent leakage, is it not the usual practice to provide the piston with a packing ring?

A. It is the usual practice.

915 X Q. Has the piston D in the drawings of patent 217,838 any packing ring?

A. No.

916 X Q. Is it not a fact that, in the tests you saw Mr. Boyden make in Baltimore on April 12th, 1894, that in the *fifth* test thereof, as testified to by Mr. Boyden, when the engineers' valve was placed in position for an emergency application, all the fifty brakes on the test-rack applied in ten and a half seconds, and the air was discharged from the train-pipe through the passage C of the valve devices of patent No. 217,838?

Objected to as immaterial, it appearing by the testimony of the witness that the experiments made by Mr. Boyden at Baltimore were made with valve devices not in accordance with patent 217,838, and the results of such experiments, therefore, not being material. And further objected to as not proper cross-examination, and as embodying the assumption that the valve devices experimented with *were* in accordance with patent 217,838.

A. The devices tested by Mr. Boyden worked substantially in the manner described in his testimony, with respect to the fifth test.

917 X Q. In the fifth test made by Mr. Boyden, which you saw, the application of the fifty brakes was quickened, was it not, by the discharge of the train-pipe air through the passages C of the valve devices he used?

Objected to as immaterial, for the reason stated in the last preceding objection.

A. It was.

918 X Q. The valves used by Mr. Boyden in the tests made by him, and which in the fifth test caused the brakes to apply quicker by discharging the train-pipe air through the passages C, were the same valves, were they not, which you have criticised because the pistons D fit so loose as to form what you say are considerable leakage passages?

A. Yes.

919 X Q. You say in answer to Q. 892:

"From this description it will be seen that, unless piston D is tightly fitted in its cylinder, a reduction of pressure in passage A would not effect a movement of piston D or an opening of passage C."

In view of the fact that the valves you saw Mr. Boyden test did open to discharge train-pipe air from the passages C, is it not evident that the pistons D of those valves fitted as tight as the patent 217,838 contemplated?

A. They undoubtedly did not fit as tight as the patent contemplated, for the reason that the tests made by Mr. Boyden showed conclusively that a reduction of pressure could be made in passage

1355 A, sufficiently great to set all the fifty brakes with full force, without the movement of piston D. The patent specifically states that, should the pressure in the front part of the pipe communicating with A be reduced intentionally or by accident, the piston D will be pressed down and the valve F withdrawn from its seat.

920 X Q. You say in answer to Q. 892:

"From this description it will be seen that unless piston D is tightly fitted in its cylinder, a reduction of pressure in passages A would not effect the movement of piston D or an opening of passage C."

In view of the fact that the valves you saw Mr. Boyden test on April 12th did open to discharge train-pipe air from the passages C in the fifth test, where the brakes were to be applied quickly, is it not evident that the pistons D of those valves fitted as tight as the patent 217,838 contemplated?

Objected to as fully answered in reply to X Q. 919, wherein the witness states that the valves undoubtedly did not fit as tight as the patent contemplated, and gives his reason shown by the tests made by Mr. Boyden.

Counsel for defendants objects to the objection as being useless

and improper and in the nature of testimony, and because if the question was believed and understood that the question as last presented, which differed from the former question, had been fully answered, it was proper for him alone to say so. Counsel for complainants suggests that the propriety of objections should be best determined by the court.

A. They did not fit as tightly as the patent contemplated, for the reason already stated, namely, that previous tests showed that a complete exhaustion of train-pipe pressure could be made and the brakes set with full force without causing the opening of the passages C.

921 X Q. Was the previous test made by Mr. Boyden, to which you refer, the one he has designated "second," where the engineers' valve handle was placed in the "graduating position?"

A. Yes.

922 X Q. Please to point out, if you can, in the specification of patent 217,838, any direction that the proportions of the parts as shown in the drawings, or the fits of the parts, shall be adhered to.

A. Referring to the specification, I find this statement: "And I do hereby declare the following to be a full, clear, concise and exact description thereof, reference being had to the accompanying drawings making a part of this specification." And I also find the following matter contained in the specification: "The form or construction of the relief valve, its function and operation being substantially retained, may be varied considerably, in so far as it is an element in the described combination, without any material departure from the scope of the invention."

It seems perfectly clear to me that these instructions and statements clearly indicate that the functions and proportions of the device, as described and illustrated, are to be retained, whatever changes may be made in its form or mode of construction.

A reference to the drawings also clearly shows that they are suitable for working drawings, and were probably copied from them, and there is no reason to believe that valves made in accordance with these drawings would not operate substantially in accordance with the description of the patent.

923 X Q. Referring to your answer to Q. 896, I ask what "intended operation of the device of patent 217,838" was destroyed, as you say, by making the pistons D one sixty-fourth of an inch smaller?

A. The downward movement of piston D and opening of piston C, when a reduction of pressure was made in the front of the train-pipe communicating with passage A, except when excessive or unusual reduction of pressure was made in the front of the train-pipe.

924 X Q. Is the excessive or unusual reduction of pressure made in the front end of the train-pipe, such a reduction as was made by the engineers' valve in the year 1879, when the

engineer desired to apply the air brakes in the shortest time and with the greatest power?

A. Yes.

925 X Q. Then I understand from your testimony that the valve devices which Mr. Boyden tested in your presence, would not open the passages C when the engineers' valve handle was placed in the graduating position to slowly apply the brakes, but that said passages C did open when the engineers' valve handle was placed in the emergency position to quickly apply the brakes with full forces; am I correct?

A. In the experiments made by Mr. Boynton the brakes were applied with full force when the handle of the engineers' valve was placed in graduated position, but there was no opening of the passages C with the handle of the engineers' valve in this position. The brakes were applied with full force, and more quickly, when the handle of the engineers' valve was placed in the emergency position and air escaped from the passages C from the train-pipe to the atmosphere.

926 X Q. In the graduating test made by Mr. Boyden, when the engineers' valve handle was placed in the "graduating position," and then blanked, were not the brakes gradually and partially applied?

A. They were.

927 X Q. Then my last previous question 925 could have been correctly answered by a simple affirmative response, could it not?

A. I think it is more completely answered in the response made to that question, as I desired to have it clearly understood that a full application of the brakes was made with the handle of the engineers' valve in the graduating position, as well as in the emergency position.

It might have been inferred from the question that a full application of the brakes was not obtained with the handle of the engineers' valve in the graduating position.

1358 928 X Q. In your answer to questions 897 and 898, you state that "brakes are very frequently released with the handle of the engineers' valve in the running position." Now, I ask, would you, as an officer of the Westinghouse Air Brake Company, recommend the practice of releasing the brakes in a fifty-car train, when using a Westinghouse engineers' valve, like that used by Mr. Boyden in his tests, by placing the handle of the engineers' valve in the running position, and not in the full release position?

A. I should not recommend the use of the port of the running position of the engineers' valve used by Mr. Boyden in his tests, under all circumstances, for the purpose of releasing brakes on a fifty-car train, but it certainly can be used to very great advantage, for the purpose of releasing brakes under the conditions named, and in regular practice is made use of for that purpose. I certainly should not consider valve devices that could not be released on a fifty-car train by the use of this method of releasing brakes, to be of any practical value, particularly when operated under the conditions that existed when Mr. Boyden made his tests.

929 X Q. Do you not, in any of your books of instruction or descriptive catalogues of air brakes, as issued by your company, distinctly state, that the handle of the engineers' valve should be placed in the full release position, and after the brakes have released, return the handle to the running position?

Objected to as immaterial.

A. Our most recent printed instructions state that on trains of moderate length, the brakes can be released and auxiliary reservoirs recharged, by placing the handle of the engineers' valve in running position. Previous publications have instructed engineers to handle the valve substantially in the manner described in your question.

930 X Q. In your answer to Q. 898, you give expression to your views as to how different parts of the air brake should operate; this testimony has reference, as it not, to the superior air brakes that are in use at this present time?

A. In reading over the answer of the question referred to, I find that any opinions that I expressed in that answer, relative to the working of air brakes, were intended to apply to automatic brakes as they were made in 1879.

931 X Q. Please state whether the engineers' valve which you saw Mr. Boyden use in the tests he made, and which you referred to in your answer to Q. 898, was the kind of engineers' valve that was in use in the year 1879?

A. It was not.

932 X Q. Then so much of your answer to Q. 898 as related to the working of air brakes by this engineers' valve, was not intended to apply to automatic brakes as they were made in 1879. Am I not right?

A. The answer in question was not given for the purpose of stating any particular method of operating any particular kind of brake at any particular time. What I wished to express, in a general way, was the fact that automatic brakes in good condition should be readily released by a very moderate increase of pressure in the train-pipe. It is a matter of no importance what kind of an engineers' valve is used for this purpose.

H. H. WESTINGHOUSE.

Adjourned *sine die*.

1361

Opinion.

Filed March 11, 1895.

In the Circuit Court of the United States for the District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE AIR BRAKE COMPANY vs. THE BOYDEN POWER BRAKE COMPANY.	}	In Equity.
---	---	------------

MORRIS, *District Judge* :

This is a bill in equity, in usual form, charging the defendant with infringing the Westinghouse patent No. 360,970, dated March 29, 1887, for a fluid-pressure automatic brake mechanism.

The claims alleged to have been infringed by the defendant, are claims 1, 2 and 4, which are as follows :

"1. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, a triple valve, and an auxiliary-valve device, actuated by the piston of the triple valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air pipe to the brake-cylinder, substantially as set forth.

"2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air pipe to the brake-cylinder, substantially as set forth.

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere respectively, and an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake-cylinder, respectively, set forth."

The only defence now urged by the defendant is non-infringement.

The history of the pioneer inventions of George Westinghouse, Jr., in fluid pressure brakes, by means of which the brakes of a train of railroad cars can be operated by air pressure controlled by the engineer of the train, and the history of the successive steps and inventions by which he has devised mechanisms adapted to apply that power so as to act automatically on each car, and the scope and fundamental importance of his later inventions by which he has accelerated in an astonishing degree, the quickness with which the brakes can be applied almost simultaneously on each car of a long

train consisting of as many as fifty freight cars, has been carefully and fully stated by Judge Townsend, who delivered the opinion in the case of *Westinghouse vs. New York Air Brake Co.*, 59 Fed. Rep. 962, and in the opinion of Judge Lacombe, filed December 27, 1894, in a case between the same parties in the United States circuit court for the southern district of New York.

The patent now in suit, No. 360,070, March 29, 1887, is the first of the Westinghouse patents in which he describes an additional function engrafted upon his automatic air brake, which is intended to be used only in cases of unusual emergency and which is intended to meet the difficulties of applying air brakes quickly on long trains. The purpose of the device was to increase the quickness of the serial action of the automatic brake mechanism on each successive car by making the triple-valve device of each brake mechanism set in operation the valves on the car immediately in its rear, and at the same time to make use of the train-pipe air vented for this purpose from the train-pipe at each triple valve, so as to add its power to the power supplied from the auxiliary reservoir of each car.

The result which Westinghouse was seeking in the new device described in patent No. 360,070, was first and principally to vent the train-pipe at each car so as to quicken the serial action of the brakes from car to car; and, secondarily, to utilize the vented air and not waste its power.

Westinghouse discovered that he could accomplish this result by so constructing the ordinary triple valve of his automatic mechanism that, in an emergency, the engineer by widely opening his engineers' valve, and thereby causing sudden and unusual release of pressure in the train-pipe could cause the piston of the triple valve to make an unusual and further traverse and thereby actuate a valve, which opened a port by which the train-pipe air was admitted suddenly and directly into the brake-cylinder, without passing through the auxiliary reservoir.

This sudden release of air from the train-pipe vented that pipe at the first car, and that venting in like manner released the pressure in the train-pipe at the valve of the next car, and so on from car to car with almost instantaneous rapidity.

It is shown that this device, as first constructed, was not entirely successful. It applied the brakes with greatly increased serial rapidity as compared with any former device and with much greater power, but not so quickly—but that the rear cars impinged against the forward ones with destructive shocks.

The reason for this appears to have been that the operation of venting was not carried far enough, because the port opened by the auxiliary valve was not of sufficient size and did not release the full volume of train-pipe air suddenly enough to vent it sufficiently. This defect was remedied by an improved mechanism devised by Westinghouse and described in his patent No. 376,837, January 24, 1888.

The success of this improved device has demonstrated that the invention by which the further traverse of the triple-valve piston

beyond the extent of the traverse required for the ordinary application of the brakes is made to admit a large volume of train-pipe air directly to the brake-cylinder was one of great importance.

1364 The proofs show that a quick-action automatic brake, which would give the results which this brake has accomplished, was eagerly sought after by inventors and car-builders, and all had failed, until Westinghouse discovered that it could be done by this mode of operation.

In the cases above referred to, in which this patent, No. 360,070, and the improvement on it, No. 376,837, were discussed with reference to the state of the art and the scope of the invention therein disclosed, these were held to be patents of a fundamental pioneer class describing an invention of primary importance.

In those cases the defendants, who were charged with infringing, were using a separate and independent valve to open the port to the train-pipe, and the question was whether or not Westinghouse was restricted to the form of independent valve and the precise mode of actuating it set out in his patent. It was held that he was entitled to a liberal construction of his claims, and that, in respect to the emergency valve, the form of his device was not of the essence of his invention.

In the Boyden mechanism, which is alleged in this case to infringe, I have not been able to satisfy myself that Boyden makes use of an auxiliary valve in the sense in which that term is employed in the specification and in some of the claims of the patent No. 360,070, now in suit.

It appears from the specification of patent No. 360,070, that what Westinghouse meant by the auxiliary valve, which is made one of the elements of the combination in the first and fourth claims, is such a valve as he has described in his specification, and which is independent of and performs none of the functions of the main valve of the ordinary triple-valve device, and I am not satisfied, notwithstanding the very positive testimony of the complainants' experts, that the poppet valve 22 of the Boyden mechanism is such a valve, for Boyden's poppet valve 22 does, as I understand its operation, to some extent perform the functions of a main valve of the triple valve, as well as the function of Westinghouse's auxiliary quick-action or emergency valve.

1365 It is probably true that in the Boyden mechanism, the stem valve *i, k, j*, which I take to be the equivalent of the sensitive graduating valve shown in the Westinghouse patent No. 220,556, October 14, 1879, is so constructed that it may do, and probably in most cases does do, the work of ordinary breaking, that is to say, that by two or three successive applications of pressure through that smaller and more sensitive valve the brake-cylinder is filled and the main valve 22 becomes non-essential, or, if lifted off its seat, is moved very gently; but valve 22 will, if the engineer uses his brake-valve carefully, do the work of a main valve, as is demonstrated, I think, by the experiments in which the sensitive graduating valve *i, k, j*, was plugged up. So I take it that defendants' valve *i, k, j*, must be held to be the sensitive graduating valve

usual in triple-valve devices since the Westinghouse patent No. 220,556; and the defendants' valve 22 must be considered to be the main valve, and that in defendants' mechanism he has been able, by an ingenious arrangement restricting the admission of auxiliary reservoir air to the triple-valve chamber, to cause the main valve to do both main valve work, when needed, and to do quick-action work when needed.

As by the explicit terms of claims 1 and 4, Westinghouse has restricted himself, as to those claims, to an auxiliary valve independent of the triple valve, I hold that the defendant does not infringe those claims.

Claim 2.

Claim 2 reads as follows:

"2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air pipe to the brake-cylinder, substantially as set forth."

The first three elements of this claim are the usual mechanism of an automatic air brake; the remaining element, which was the only novel one at the date of the patent, is a triple valve having a piston which by two distinct movements performs two distinct functions, the first its preliminary traverse by which it admits air from the auxiliary reservoir to the brake-cylinder, which is the ordinary effect of the usual movement of the triple-valve piston, and the second, its further traverse, which is a new and distinct use, admitting air directly from the main air pipe to the brake-cylinder, resulting in venting the main air pipe and in producing the quick action.

Now this, as I understand it, was the invention which Westinghouse brought to light. He discovered, and by experiment demonstrated, that by a further traverse of the triple piston train-pipe air could be vented from the train-pipe and that it would give two very important results, namely, first, quickening of the action of the brakes from the forward to the rear cars, so that the application of the brakes became almost instantaneous on all the cars, and, second, utilizing the vented air for direct action in the brake-cylinder. Now, although quick-action emergency brakes were being sought for, no one before Westinghouse had accomplished this result, and the means by which he accomplished it were entirely novel. Indeed, upon first impression it is paradoxical and startling to find that when a sudden, quick and powerful application of brakes is needed in the face of impending danger, it is to be obtained by a sudden large release of the pressure in the train-pipe, to the extent of fifteen or twenty pounds below that in the auxiliary reservoir, and that by using this low-pressure air to operate the brake-cylinder, instead of the air under greater pressure stored in the auxiliary reservoir, this remarkably effective application of the brakes is obtained. In the domain of quick-action brakes, this device would

seem to belong to that class of pioneer inventions, the patents for which are to be construed so as to be coextensive with the real invention, if the language of the claim will permit it.

It is shown that Westinghouse was the first who used a further traverse of the triple-valve piston to perform the operation required to vent the train-pipe into the brake-cylinder, to effect quick action. The result was new and the means were new. His claim 2 is broad enough in language to cover every device in which that is
1367 done by the further traverse admitting air directly from the train-pipe to the brake-cylinder, substantially by the means described in the specification, that is, by the further traverse actuating a valve which so admits the train-pipe air.

The result accomplished by defendant's mechanism is identical with that of Westinghouse, and the means by which the mechanism is actuated so alike that in its published trade catalogue defendant claims that cars fitted with its valves can be used on the same trains with the Westinghouse quick-action brake, because the engineer in applying or releasing the air pressure may treat them as identical; the same functional operations of the valves and the same results being obtained from the same changes in the engineers' brake-valve, so that there is strong *prima facie* reason to suppose that Boyden's way of using the same release of pressure to vent the train-pipe and to actuate the valves, which produces identical results, may be Westinghouse's way.

In mechanisms actuated by air under pressure, the transmission of power is not visible to the senses as plainly as when it is done by cranks and levers, and being transmitted by an invisible agency in all directions in which the air can escape, the functions of the instrumentalities by which it operates are more important than their forms, and in judging of an infringement we are to direct our minds rather to functional equivalents than mechanical equivalents.

The use by Boyden of a central opening through the triple-valve piston to admit train-pipe air to the triple-valve chamber was not new, nor the use of a poppet valve for the main valve of the triple, both of these constructions having been shown in the Westinghouse patent No. 141,685, August 12, 1873, and in others of his patents. So that there is nothing in the Boyden device not before exhibited in some one of the Westinghouse patents, except that he has been able to cause one of the valves of the triple (valve 22) at one stage of the application of brakes to perform ordinary service work, and at another to do quick-action works. This Boyden does by ingenious construction not before used, by which he restricts the passage of auxiliary reservoir air into the triple-valve chamber, so
1368 that when the further traverse of the piston suddenly unseats the poppet valve 22 the port opened by it to the brake-cylinder is so large and the supply of auxiliary reservoir air through the restricted passage so feeble, that the train-pipe air raises its check-valve and vents itself into that chamber and thence through the large port to the brake-cylinder. For the mechanism embodying this ingenious contrivance by which the poppet valve 22 is made capable of doing ordinary service work by a careful intermittent,

slow release of pressure by the engineer, and quick-action work by a quick sudden release, patents were granted to Boyden (No. 481,134, August 16, 1892, and No. 481,135, August 16, 1892); but if this construction contains the underlying invention of the patent in suit, which was granted March 29, 1887, Boyden cannot make use of his improvement during the life of that patent.

It is true that in searching for some device which would give quick action, Westinghouse had, before the date of the patent in suit, conceived the idea that it might be accomplished by venting the train-pipe at intervals along the train. He had tried having two or three vents at intervals in the length of the train controlled by electrical apparatus, and also had tried relief valves placed in pipe coupling of each car which would open to the atmosphere and vent the train-pipe quickly in case of accident or other sudden release of pressure in the forward part of the train. This was shown in the Westinghouse patent No. 217,838, July 22, 1879, but neither of these attempts were successfully applied, and they did not solve the problem of quick action.

The problem was not solved; indeed, the first step in the direction of solving it does not appear to have been taken until the experiments which led to the Westinghouse patent now in suit. The substance of the method then devised is the use of the sudden further traverse of the triple-valve piston to open a valve in a manner different from the valve opening made by the preliminary traverse for service braking, thereby admitting train-pipe air to the brake-cylinder without its passing through the auxiliary reservoir.

In the Westinghouse apparatus the further traverse of the triple-valve piston causes it to impinge against an additional separate valve which admits the train pipe air. In Boyden's apparatus used by the defendant, the further traverse pulls the poppet valve 22, which Boyden substituted for the ordinary main valve of the triple, suddenly off its seat, thereby, in the manner before mentioned, causing the train-pipe air to raise the check-valve and flow with volume through the triple-valve chamber direct to the brake-cylinder. The device in Boyden's apparatus, by which the difference of pressures in the triple-valve chamber between auxiliary reservoir air and the train-pipe air is produced and used, is ingenious and admirable; but the result obtained is just the same as when in the Westinghouse apparatus the auxiliary valve is unseated, and the means used are, in my judgment, functionally equivalent.

Under the ruling of *Morley Machine Co. vs. Lancaster*, 129 U. S., 263, and of the many cases cited in the opinion delivered in that case, the rights of a pioneer inventor are infringed by one who accomplishes the same result by means which, although never used for that purpose before, are mechanical equivalents for the means used by the inventor under a liberal construction of his patent. It was said in that case by Mr. Justice Blatchford (page 273): "Where an invention is one of a primary character and the mechanical functions performed by the machine are, as a whole, entirely new, all subsequent machines which employ substantially the same

means to accomplish the same results are infringements, although the subsequent machine may contain improvements in the separate mechanisms which go to make up the machine."

In *McCormick vs. Talcot*, 20 How., 402, the controversy arose over a device which McCormick had added to his reaper called a divider, intended to separate the standing grain to be left from that which is to be cut. The court said: "If he be the original inventor of the device or machine called the divider, he will have the right to treat as infringers all who make dividers operating on the same principle and performing the same functions by analogous means or equivalent combinations, even though the infringing machine be an improvement of the original, and patentable as such."

In *Machine Co. vs. Murphy*, 97 U. S., 120-125, it was said: "Nor is it safe to give much heed to the fact that the corresponding device in two machines organized to accomplish the same result is different in shape or form the one from the other, it is necessary in every such investigation to look at the mode of operation or the way the device works, and at the result, as well as at the means by which the result is attained."

The language of the Supreme Court in *Consolidated Valve Co. vs. Crosby Valve Co.*, 113 U. S., 157-171, is applicable:

"The prior structures never effected the kind of result attained by Richardson's apparatus because they lacked the thing which gave success. * * * Taught by Richardson, and by the use of his apparatus, it is not difficult for skilled mechanics to take prior structures and so arrange and use them as to produce more or less of the beneficial results first made known by Richardson."

It is true that a patentee can claim nothing beyond the scope of his patent (*Keystone Bridge Co. vs. Phoenix Iron Co.*, 95 U. S., 27-28) but the scope and meaning of a broad claim in the patent can only be interpreted by an understanding of the real scope of the invention itself.

If the Westinghouse patent now in suit is for an invention of primary character, and if the gist of that invention is the use of the further traverse of the triple-valve piston to open a valve which admits air directly from the train-pipe to the brake-cylinder, with the result that the train-pipe is vented and the train-pipe air utilized, then it appears to me that the defendant cannot exculpate itself from the charge of infringement by the fact that in its device the train-pipe air is admitted through the triple-valve chamber and not through a by-passage, nor by the fact that in its device the further traverse of the piston opens the main valve in a special manner which produces the same result, but does not make use of a separate auxiliary valve, provided Westinghouse has not by the explicit terms of his claim 2 restricted himself to the use of an auxiliary valve.

I do not think Westinghouse has so restricted himself in claim 2, although he does appear to have done so in claims 1 and 4.

There is without question some difficulty and embarrassment in the broad construction of claim 2, growing out of the proceeding in 1371 in the Patent Office, as shown by the file-wrapper and con-

tents; but considering what was the real invention, I am not of the opinion that the legal effect of those proceedings is to restrict claim 2 to a device containing a separate auxiliary valve.

From the contents of the file-wrapper it appears that, as the application was prepared, the first claim of patent No. 360,070 differed from that which now appears in the patent as granted.

The claim 1 first proposed was: "1. In a brake mechanism the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, a triple valve provided with a device for admitting air directly from the main air pipe to the brake-cylinder, substantially as set forth."

It was objected by the Patent Office examiner that this claim and also claim 2 were anticipated by patent No. 280,285, to G. A. Boyden, June 26, 1883, and the examiner requested that a working model of the triple valve should be furnished.

Boyden's patent of 1883, No. 280,285, was a form of triple-valve mechanism intended for use with Westinghouse's automatic air brake, the object of which was to provide for replenishing the auxiliary reservoir of each car when the pressure therein had been lessened by leakage and while the brakes remained applied. This was done by the engineer causing, not a release, but a slight increase of the pressure in the train-pipe air, which, acting upon a check-valve in the centre of the triple-valve piston, by a peculiar arrangement of the valves, caused train-pipe air to pass together with auxiliary reservoir air to the brake-cylinder. The object, function and result of whatever was new and patentable in this Boyden device was altogether different from the object, function and result of the Westinghouse device in patent No. 360,070, and there seems to be no analogy or comparison which can be made between them.

It is true that the "always-open one-way passage" in the Boyden patent which, when the check-valve was raised, allowed train-pipe air to reach the brake-cylinder, was, in the language of the cancelled claim 1 of No. 360,070, "a device for admitting air directly from the main air pipe to the brake-cylinder," and there were 1372 other devices used by Westinghouse himself which this wording would include; and the claim was, therefore, justly open to the criticism of the patent examiner, but there was no similarity in the means by which the two devices were actuated, no similarity in the object to be accomplished and no similarity in the mechanical principle of operation. It was simply a fact that there did exist in the Boyden device a passage for train-pipe air direct to the brake-cylinder which the engineer could cause to open by a slight increase of train-pipe pressure; but there was no hint or suggestion of the important discovery how that fact could be utilized to accomplish the entirely new function necessary to create a quick-action brake when, in an emergency, quick action was needed; and how, when quick action was needed, it should not interfere with ordinary graduation and service stops. This Boyden device was not in the direction of quick action, but its opposite.

While, therefore, it was proper that Westinghouse's original claim 1, should be corrected so as to express more definitely his

real invention, this was not because the Boyden patent in any manner whatever anticipated that invention or suggested it in any of its functions.

For the same reason there was then inserted in the specification of the Westinghouse patent No. 360,070, this clause:

"I am aware that a construction in which 'an always-open or way passage' from the main air pipe to the brake-cylinder is uncovered by the piston of the triple valve simultaneously with the opening of the passage from the auxiliary reservoir to the brake cylinder has been heretofore proposed, and such construction, which involves an operation different from that of my invention, I therefore hereby disclaim."

In the Boyden infringing device now used by the defendant, the passage from the main air pipe to the brake-cylinder is not "uncovered by the piston of the triple valve simultaneously with the opening of the passage from the auxiliary reservoir to the brake cylinder;" if it was, the defendant's mechanism would be always a quick-action brake and never anything else, but, on the contrary, in the infringing device, the passage is not opened until there has been a sudden further traverse of the piston, which the 1373 brings it into operation for the distinct purpose of quick action. The statement of the so-called disclaimer is strictly true that the construction of the Boyden 1883 patent "involves an operation different from" the Westinghouse invention, and the so-called disclaimer in reality disclaims nothing which has relation to the Westinghouse quick-action invention.

The disclaimer was substituted in the place of the following which had been in the specification and was cancelled:

"Further, while in the specific construction described and showing the function of admitting air from the main pipe is performed by a valve separate from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve integral with the main valve and formed by an extension thereof, would be included in and embodied the essential operative features of my invention."

The testimony tends to prove that this clause of the specification was taken out because the examiner objected that no such form of triple valve was illustrated in the drawings. For whatever reason it may have been cancelled, it is not a necessary result that the patentee is precluded from claiming that his patent covers other forms of valve integral with the main valve, if such is his legal right when his invention, as disclosed in his patent, is found to be a broad one, and if he is not restricted by his claims and if he has done nothing to impair his right to be protected in his whole invention. The effort should be to preserve, rather than to forfeit the inventor's rights.

Keystone Manufacturing Co. vs. Adams, 151 U. S., 144.

The object and scope of the invention and the means employed to effect his object are thus stated by Westinghouse in the specification of his patent in suit.

"The object of my invention is to enable the application of brake-shoes to car wheels by fluid pressure to be effected with greater rapidity and effectiveness than heretofore, more particularly in trains of considerable length, as well as to economize compressed air in the operation of braking by utilizing in the brake-
 1374 cylinders the greater portion of the volume of air which in former practice was directly discharged into the atmosphere. To this end my invention generally stated, consists in a novel combination of a brake-pipe, an auxiliary reservoir, a brake-cylinder, and a triple-valve device governing, primarily, communication between the auxiliary reservoir and the brake-cylinder; and, secondarily, communication directly from the brake-pipe to the brake-cylinder."

This language exactly describes the infringing mechanism of the defendant.

The amendments made to meet the objections of the patent examiner are not to be construed to disclaim the patentee's actual invention, if such construction can be avoided without doing violence to the obvious meaning of the language.

Lake Shore Railway Co. *vs.* Car Brake Co., 110 U. S., 229-236.

Reese Button Hole Machine Co. *vs.* Globe Button Hole Co., 61 Fed. Rep., 956.

It has been urged that the invention disclosed by the patent in suit is not of a meritorious character because in the form in which it is there embodied, or at least in the first mechanism manufactured by Westinghouse, it failed of success in some essentials, and was immediately improved by Westinghouse in a manner which was the subject of a subsequent patent, before it was successful in the use for which it was intended. The defect developed by experimental test and which Westinghouse in a few months remedied was that the opening uncovered by the auxiliary valve was not sufficiently large to suddenly release the full volume of train-pipe air. This was not a defect inherent in the device.

59 Fed. Rep., 581-591.

There were structural objections to making that opening large, but when made larger, the device answered the purpose for which it was intended. It was thought, however, better to remedy the difficulty by adding an auxiliary piston as well as an auxiliary valve, and it was in that line that Westinghouse carried his further improvements, and he has adopted that form as the best to be manufactured for general use.

1375 This defect in the patent in suit was not radical and was only one of those defects common in the first forms of many pioneer inventions which usually have to be improved upon before they attain commercial success.

It is further urged that in a doubtful case the scale should be turned by the fact that subsequent to the date of the patent in suit, indeed more than two years after the institution of this suit, patents

Nos. 481,134 and 481,135, August 16, 1892, were granted to Boyden for the mechanism now used by the defendant.

Boyden was entitled to patents for whatever was a patentable novelty in the devices by which he was able to make his valve 22 answer for both service and quick-action work in connection with the restricted passage B, and for any other patentable novelty in the forms of his mechanism. The widely different forms in which he has illustrated his devices in the two above-mentioned patents show that taking what Westinghouse had discovered and demonstrated to be the underlying principle of a quick-action brake, a skillful and inventive mechanic can devise many forms for applying it.

But in his specification of patent No. 481,134 and No. 481,135, Boyden alleges that his device differs essentially from Westinghouse's patent No. 360,070, and involves a new mode of operation. The question whether it does or not was the very question pending in this suit, and so far as the examiner passed upon it in allowing the specification to stand, he did so upon the *ex parte* application of Boyden and unassisted by testimony as to the state of the art at the date of the Westinghouse patent, without testimony as to the scope of the Westinghouse quick-action invention and its great importance and merit; and, therefore, without the opportunity of judging whether or not it was a pioneer invention of a fundamental character entitled to a construction coextensive with the invention, or was simply a patent for an improvement in a known art to be restricted to the form of the device shown in the model and illustrations.

The determination of that question is the starting point in 1576 the consideration of the controversy, and, in my judgment, the fact that Westinghouse was the first discoverer of the vital underlying invention, should turn the scale in his favor.

The complainants are entitled to a decree for an injunction and account, with a reference to a master in the usual form.

Decree.

Filed April 25, 1895.

United States Circuit Court, District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE
AIR BRAKE COMPANY

vs.

BOYDEN POWER BRAKE COMPANY; GEORGE A. BOYDEN,
President; Charles B. Mann, Secretary; William
Whitridge, Treasurer, and Boyden Brake Company.

In Equity.
No. 321.

And now, to wit, this 25th day of April, 1895, the above-entitled cause having come on regularly for hearing, before the Honorable Thomas J. Morris, district judge, holding circuit court, on bill, answer, replication and proofs taken by and on behalf of the respective parties hereto, and having been argued by Mr. George H. Christy

and Mr. Frederic H. Betts, for complainants, and by Mr. Lysander Hill, Mr. Skipwith Wilmer and Mr. Hector T. Fenton, for defendants, and the court having considered the same, and being duly advised in the premises, it is thereupon ordered, adjudged, and decreed:

377 1st. That the letters patent recited in complainants' bill of complaint, to wit, letters patent of the United States, No. 360,070, dated March 29, 1887, and granted to George Westinghouse, Jr., for a new and useful improvement in fluid-pressure automatic brake mechanism, are a good and valid patent in all respects as regards and to the extent of the subject-matter of invention referred to and summed up in the several claims declared upon herein, to wit, claims numbered one, two and four of said recited patent; that George Westinghouse, Jr., was the true, original and first inventor thereof; and that the complainants have a good and sufficient title thereto, and are entitled to the exclusive right therein and thereunder.

2d. That the defendants above named, by the manufacture, use and sale of fluid-pressure automatic brake mechanism, as set forth and shown in and by the proofs herein, and (for greater certainty herein) more particularly as shown and described in certain letters patent of the United States, No. 481,134 and No. 481,135, both dated August 16, 1892, and both granted to The Boyden Brake Company, assignee of George A. Boyden, defendants herein, have infringed the said second claim of said recited patent No. 360,070, and have violated the exclusive right of the complainants therein and thereunder, and that a writ of injunction, conformable to the prayer of said bill, and in the usual form, be issued by the clerk, perpetually enjoining and restraining the said defendants and each of them from any further manufacture, use or sale of the apparatus, mechanism and devices complained of herein, and of and other apparatus, mechanism or devices substantially such in construction and operation as that which is referred to in and constitutes the subject-matter of said second claim, and from doing any act or thing in infringement of said second claim, or in violation of the exclusive right so as aforesaid vested in said complainants therein and thereunder.

3d. That reference be made herein to G. Morris Bond, Esq., as master, to take, state and make return of an account of the gains and profits made by said defendants, as also of the damages suffered by said complainants by or on account of said infringement, 1378 and that the parties appear before the master and produce books and papers and render accounts as he may, from time to time, direct.

4th. That as regards claims one and four of said patent No. 360,070, the court being of the opinion that defendants' device hereinbefore referred to does not infringe the same, injunction is refused and the bill of complaint is, in reference to such claims, hereby dismissed.

5th. And it is further ordered that all questions of the allowance of costs are reserved until the final decree.

THOS. J. MORRIS, *Judge.*

Petition for Appeal; Order Thereon Allowing the Appeal and Assignment of Errors.

Filed April 29, 1895.

United States Circuit Court, District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WEST-
INGHOUSE AIR BRAKE COMPANY
vs.

BOYDEN POWER BRAKE COMPANY; GEORGE
A. Boyden, President; Charles B. Mann,
Secretary; William Whitridge, Treasurer,
and Boyden Brake Company. } In Equity. No. 321.

To the Hon. Thomas J. Morris, judge:

And now, April 29th, 1895, come the defendants into court by Messrs. Barton and Wilmer their solicitors, and pray for allowance of an appeal to the United States circuit court of appeals for 1379 the fourth circuit from the interlocutory decree in said cause entered the 25th day of April, 1895, awarding an injunction and account as prayed in the bill of complaint in respect of the 2d claim of the letters patent in suit, that a proper citation may be issued and served upon the plaintiffs in said case, or their solicitors, and that a transcript of the record, proceedings and evidence in said case, duly authenticated, may be transmitted to said circuit court of appeals.

BARTON & WILMER,
Sol's for Defendants.

Whereupon it is now ordered this 29th day of April, 1895, that said appeal be and is hereby allowed.

And it is further ordered that security on appeal in the sum of five hundred dollars be entered by the appellants.

THOS. J. MORRIS, *Judge.*

Assignment of Errors.

United States Circuit Court of Appeals, Fourth Circuit.

THE BOYDEN POWER BRAKE COMPANY *et al.*, Appel-
lants and Defendants Below,

vs.
GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE
AIR BRAKE Co., Appellees and Plaintiffs Below. } In Equity.

And now, April 29th, 1895, come the appellants in above case, by their counsel, and say that in the record and proceedings therein there is manifest error in this, to wit:

1380 1st. The circuit court erred in adjudging the 2d claim of the patent in suit to be valid, because it is functional in form

and therefore legally incapable of interpretation as for a combination of mechanism.

2d. The circuit court erred in its interpretation of the 2d claim of the patent in suit, because said claim being functional in form, should, if capable of being sustained, have been construed to be for the mechanism described in the specification as essential in the performance of the function recited in the claim, and hence inclusive of an auxiliary valve actuated by the triple-valve piston on its further or full traverse, and thereby brought into register with an independent port and passage having no connection with the triple-valve mechanism.

3d. The court erred in its interpretation of claim 2 of the patent in suit, in that it held that said claim broadly covered any combination of valve mechanism (including a triple valve) in which train-pipe air was admitted to the brake-cylinder by a further or full traverse of the triple-valve piston.

4th. The circuit court erred in its construction of claim 2, because its adjudged interpretation thereof is based upon the erroneous premise that the "further traverse" of the triple-valve piston was a new and "unusual" motion or function of said device in this combination, whereas in truth and in fact said "further traverse" was the usual, old and ordinary function of the piston of the old and well-known triple valve; and whether new or old, usual or unusual, was and is wholly ineffectual to produce the function recited in the plaintiffs' device, without the addition of another and distinct port and passage leading to the brake-cylinder and another and auxiliary and additional valve governing the same and actuated by the triple-valve piston on its "further" traverse.

5th. The circuit court erred in construing claim 2 as a generic claim, because the plaintiff was estopped by its declarations made in its suit on its later patent No. 376,837, from claiming that the prior patent No. 360,070, in suit was in any sense a pioneer patent.

6th. The circuit court erred in broadly construing claim 2 of the patent in suit as for a combination of mechanism in which the auxiliary valve or its equivalent, as well as the port and the passage controlled thereby, need not necessarily be separate and independent of the triple-valve mechanism proper; because there is no warrant in the specification for any such interpretation of the claim.

7th. The circuit court erred in broadly construing claim 2 of the patent in suit as for a combination of mechanism in which the auxiliary valve or its equivalent, as well as the port and the passage controlled thereby, need not necessarily be separate and independent of the triple-valve mechanism proper, because the state of the art disclosed in the record legally precluded any such generic interpretation.

8th. The circuit court erred in broadly construing claim 2 of the patent in suit as for a combination of mechanism in which the auxiliary valve or its equivalent, as well as the port and the passage controlled thereby, need not necessarily be separate and independent of the triple-valve mechanism proper; because the declarations of

the patentee contained in the file of the application for the patent required as matter of law a narrower, more restricted and different interpretation.

9th. The circuit court erred in its interpretation of said second claim, because the plaintiffs' alleged invention being admittedly an improvement consisting only in the addition to the old and well-known triple-valve mechanism and without any change whatever in the latter, either in construction or function, of an independent element, arranged in juxtaposition with, so as to be actuated by, such triple-valve piston on its extreme traverse, and whereby such added element produced an additional result exclusively its own, should have been interpreted to be inclusive only of mechanism mechanically equivalent to such new and added part, and not as construed by the court to be inclusive of any mechanism generally capable of performing such new and additional result.

10th. The circuit court erred in adjudging that the defendants' apparatus infringed said second claim, because the defendants' device does not employ an auxiliary valve nor any equivalent super-added element to accomplish the new or additional result described in the claim, but performs the function and result recited in the claim by mechanism wholly different therefrom in principle of construction and operation, viz., solely by an ingenious modification of a chamber wall of the triple valve itself and without any additional passageway or port, or auxiliary valve governing such port and passage, or any mechanical equivalent for the same or any of them.

11th. That the circuit court erred in holding that the defendants have infringed the second claim of said patent No. 360,070, whereas, in law, it should have held that the defendants had not infringed said claim in view of the finding by the court that defendants poppet valve 22, is not an auxiliary valve.

12th. The circuit court erred in holding said 2d claim to be entitled to cover functional equivalents, whereas it should have held it entitled to cover only the means specified in the patent or their mechanical equivalents.

13th. The court erred in not giving proper weight and force to the disclaimers and limiting statements of the patent in suit, and to the record of proceedings in the Patent Office when said patent was applied for.

14th. The circuit court erred in granting an injunction restraining these defendants from manufacturing, selling and using air-brake apparatus constructed under, and in substantial accordance with, the patents granted to George A. Boyden, dated August 16, 1892, No. 481,134 and No. 481,135.

15th. The court erred in not giving proper weight and force to the statements contained in the patents to George A. Boyden, No. 481,134 and No. 481,135, in which the defendants' device is differentiated from the device of the patent in suit.

16th. The circuit court erred in construing the 2d claim as covering the defendants' device after finding that the poppet valve 22, must be considered to be the main valve of the triple-valve device

and admits the air from the main air pipe to the brake-cylinder, and that the device described in the specification of the patent in suit to perform that function, is a valve independent of, and performs none of the functions of, the main valve of the ordinary triple-valve device.

1383 17th. The court erred in awarding the injunction appealed from.

18th. The circuit court erred in not fully dismissing the bill.

Wherefore, the appellants, The Boyden Power Brake Company, *et al.*, pray that the decree of the circuit court of the United States for the district of Maryland, may be reversed by this honorable court, and that the said circuit court be directed by the mandate of this court to enter a decree rescinding the decree appealed from and directing a dismissal of the bill of complaint filed in said cause, with costs to the appellants and defendants below.

BARTON & WILMER,

Of Counsel for Appellants.

Appeal Bond.

Filed April 29, 1895.

Know all men by these presents, that we, the Boyden Brake Company, as principal, and Douglas H. Thomas, as surety, are held and firmly bound unto George Westinghouse, Jr., and the Westinghouse Air Brake Company, in the full and just sum of five hundred dollars, to be paid to the said George Westinghouse, Jr., and the Westinghouse Air Brake Company, his and their certain attorney, executors, administrators or assigns; to which payment, well and truly to be made, the Boyden Brake Company aforesaid binds itself and its successors or assigns, and the said Douglas H. Thomas binds himself, his heirs, executors and administrators, jointly and severally by these presents.

Sealed with our seals and dated this twenty-ninth day of April, in the year of our Lord one thousand eight hundred and ninety-five.

Whereas, lately at a circuit court of the United States for the district of Maryland, in a suit depending in said court, between George Westinghouse, Jr., and The Westinghouse Air Brake Company, complainants, and The Boyden Power Brake Company, George A. Boyden, president, Charles B. Mann, secretary, William Whitridge, treasurer, and The Boyden Brake Company, defendants, a decree was rendered against the said defendants, and the said defendants having obtained an appeal to reverse the decree in the aforesaid suit, and a citation directed to the said George Westinghouse, Jr., and The Westinghouse Air Brake Company, citing and admonishing them to be and appear at a United States circuit court of appeals for the fourth circuit, to be holden at Richmond, on the day in the said citation mentioned:

Now, the condition of the above obligation is such, that if the said defendants shall prosecute their appeal to effect and answer all

costs if they fail to make their plea good, then the above obligation to be void ; else to remain in full force and virtue.

In testimony whereof, the said Boyden Brake Company hath caused its corporate seal to be hereunto affixed, and George A. Boyden, its president, hath hereunto subscribed his name, and Douglas H. Thomas, the surety above named, hath also subscribed his name and affixed his seal, on the day and year aforesaid.

[Seal of the Boyden Brake Co.]

GEO. A. BOYDEN, *Pst.*
DOUGLAS H. THOMAS. [SEAL.]

Signed, sealed and delivered in presence of—
L. J. VAN HORN.

Approved by—
THOS. J. MORRIS, *Judge.*

1385 *Citation.*

UNITED STATES OF AMERICA, *ss :*

The President of the United States to George Westinghouse, Jr., and
The Westinghouse Air Brake Company, Greeting :

You are hereby cited and admonished to be and appear at a United States circuit court of appeals for the fourth circuit, to be holden at Richmond on the 25th day of May next, pursuant to an appeal from a decree of the circuit court of the United States for the district of Maryland in your favor, passed in a cause in said court wherein The Boyden Power Brake Company, George A. Boyden, president, Charles B. Mann, secretary, William Whitridge, treasurer, and Boyden Brake Company, are defendants, and you are complainants, to show cause, if any there be, why the decree rendered against the said defendants in said cause mentioned, should not be corrected, and why speedy justice should not be done to the parties in that behalf.

Witness, the Honorable Thomas J. Morris, judge
[COURT SEAL.] of the said circuit court of the United States, this
twenty-ninth day of April, in the year of our Lord
one thousand eight hundred and ninety-five.

THOS. J. MORRIS, *Judge.*

Test : JAMES W. CHEW,
Clerk U. S. Circuit Court, District of Maryland.

Endorsed.

Due service of the within citation acknowledged, this 29th day
of April, 1895.

BERNARD CARTER,
*Solicitor for George Westinghouse, Jr., and
The Westinghouse Air Brake Company.*

1386 *Order Permitting Withdrawal of Exhibits for Use in the United States Circuit Court of Appeals.*

Filed April 30, 1895.

United States Circuit Court, District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WEST-
INGHOUSE AIR BRAKE COMPANY

vs.

BOYDEN POWER BRAKE COMPANY; GEORGE
A. Boyden, President; Charles B. Mann,
Secretary; William Whitridge, Treasurer,
and Boyden Brake Company. } In Equity. No. 321.

Ordered by the court, this 30th day of April, 1895, that the defendants have leave to withdraw the following exhibits from the files of the court in order that they may be exhibited to the United States circuit court of appeals for the fourth circuit on the hearing of said cause on appeal.

Complainants' Exhibit, Defendants' 1891 Catalogue.

Complainants' Exhibit, Defendants' 1889 Catalogue.

Complainants' Exhibit Drawing Quick-action Automatic Freight
Brake.

Defendants' Exhibit, Westinghouse 1890 Instruction Book.

Defendants' Exhibit, Westinghouse 1886 Instruction Book.

Also such other of the original exhibits as counsel may desire to exhibit to said circuit court of appeals.

It is further ordered that before taking out said exhibits, a receipt shall be given to the clerk of the court for the return of the same after the hearing.

THOS. J. MORRIS, *Judge.*

1387 Thereupon it is ordered by the court here, that a transcript of the record and proceedings in the cause aforesaid, together with all things thereunto relating, be transmitted to the said United States circuit court of appeals for the fourth circuit, and the same is transmitted accordingly.

Test:

JAS. W. CHEW, *Clerk.*

UNITED STATES OF AMERICA, } *To wit:*
District of Maryland, }

I, James W. Chew, clerk of the circuit court of the United States for the fourth circuit in and for the district of Maryland, do hereby certify that the foregoing is a true transcript of the record and proceedings, together with all things thereunto relating, in the therein-entitled cause.

[COURT SEAL.] In testimony whereof, I hereunto set my hand and affix the seal of the said circuit court, this sixth day of May, A. D. 1895.

JAS. W. CHEW,
Clerk of said Court.

Cross-appeal of the complainants from the decree of the circuit court of the United States for the district of Maryland.

1390 UNITED STATES OF AMERICA, }
District of Maryland, } *To wit:*

At a circuit court of the United States for the fourth circuit, in and for the district of Maryland, begun and held at the court-house in the city of Baltimore on the first Monday of April, being the first day of the same month in the year of our Lord one thousand eight hundred and nine y-five—

Present: The Honorable Thomas J. Morris, judge of the Maryland district; William L. Marbury, Esq., attorney; Charles H. Evans, Esq., marshal; James W. Chew, clerk—

Among other were the following proceedings, to wit:

GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE
AIR BRAKE COMPANY, Complainants,
vs.
BOYDEN POWER BRAKE COMPANY; GEORGE A. BOY-
den, President; Charles B. Mann, Secretary; Wil-
liam Whitridge, Treasurer, and Boyden Brake
Company, Defendants. } In Equity.

1391 *Petition of Complainants for an Appeal, Order of Court Allow-
ing the Appeal, and Assignment of Errors.*

In the Circuit Court of the United States, District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WEST-
inghouse Air Brake Company, Complain-
ants and Appellants,
v.
BOYDEN POWER BRAKE COMPANY; GEORGE
A. Boyden, President; Charles B. Mann,
Secretary; William Whitridge, Treasurer,
and Boyden Brake Company, Defendants
and Appellees. } In Equity. No. 321.

The above-named complainants, George Westinghouse, Jr., and
The Westinghouse Air Brake Company, conceiving themselves ag-
grieved by so much of the interlocutory decree heretofore entered
in said cause, as relates to claims one and four of the patent in suit,
No. 360,070, do hereby appeal to the United States circuit court of
appeals for the fourth circuit from so much and such parts of said
decree as refuse an injunction under the claims numbered one and
four of the patent in suit, No. 360,070, or as contain or involve a
refusal of an injunction under said claims, and they pray that this,
their appeal, may be allowed, and that a transcript, duly
1392 authenticated of the record and proceedings in the above-
entitled cause, upon which so much of said decree was made,
may be transmitted with said appeal to the circuit court of appeals
for the fourth circuit, or if it be that such a transcript has already
been transmitted to the circuit court of appeals on the appeal of the
original defendants herein, then they pray that this, their appeal,
being a cross-appeal, may be allowed, and that a certified transcript
of so much of the record and proceedings herein as appertain to the
subject-matter of this appeal, and as have not already been certified
in said original appeal, as aforesaid, may be transmitted with this
appeal to the circuit court of appeals for the fourth circuit.

BERNARD CARTER,
Solicitor for Complainants.

Ordered, this 13th day of May, 1895, that the above appeal be
allowed as prayed for, and the clerk will certify accordingly; pro-
vided, the appellant shall refund to the appellees or to the clerk the
one-half of the cost of the transcript already transmitted.

THOS. J. MORRIS, *Judge.*

And *eo die* come the complainants in the above-entitled cause and file, with their foregoing petition for appeal, these their assignments of error:

1st. That the court erred in finding that defendants' apparatus did not contain an auxiliary valve within the meaning of claims one and four of patent No. 360,070, and of each of them.

2d. That the court erred in holding that it is an essential feature of the auxiliary valve of the patent in suit that it "performs none of the functions of the main valve of the ordinary triple-valve device."

3d. That the court erred in finding that the quick action or emergency valve 22 of defendants' apparatus is in any practical or operative or commercial sense a main valve, or that in practical use it has the capacity or does the work of a main valve, or that to any practical or material extent it "performs the functions of a main valve of the triple valve."

4th. That the court erred in holding that the valve *ij k* of defendants' apparatus is not a main valve within the meaning of claims one and four of patent 360,070 and of each or either of said claims.

5th. That the court erred in holding that the defendants' apparatus did not contain the invention of claims one and four and of each of them.

6th. That the court erred in not holding that in defendants' apparatus, and for the purposes of this case, the valve *ij k* is or represents the valvular appliance by or through which the ordinary service work of the brake is done, and valve 22 is or represents the valvular appliance by or through which quick action or emergency work is done, and also in not holding that such use and operation of defendants' apparatus involves an unauthorized use of the invention of claims one and four of patent 360,070, and is an infringement thereof.

7th. That the court erred in refusing and in not granting an injunction under each and both of said claims.

Wherefore, these appellants, George Westinghouse, Jr., and The Westinghouse Air Brake Company, pray that the decree of the circuit court of the United States for the district of Maryland may be

reversed by this honorable court in respect of the matters herein appealed, and that the said circuit court be directed

by the mandate of this court to enter a decree for an injunction and account under claims one and four of the patent in suit, No. 360,070, with costs to the appellants herein and complainants below.

BERNARD CARTER,
Solicitor for Appellants.

Service of copy of the within admitted this 13th day of May, 1895.

BARTON & WILMER,
Solicitors for Defendant.

Complainants' Appeal Bond.

Filed May 13th, 1895.

Know all men by these presents that we, George Westinghouse, Jr., and the Westinghouse Air Brake Company, as principals, and W. J. C. Dulany, of Baltimore, Maryland, as surety, are indebted to Boyden Power Brake Company, George A. Boyden, president; Charles B. Mann, secretary; William Whitridge, treasurer; and Boyden Brake Company, in the penal sum of five hundred dollars, good and lawful money of the United States, for the payment of which, well and truly to be made, we do bind ourselves, our successors, heirs, executors and administrators jointly and severally by these presents.

In testimony whereof, the said obligors above named have hereunto affixed their respective hands and seals this 13th day of May, A. D. 1895.

The condition of the above obligation is such that, whereas, in the cause now pending in the circuit court of the United States in and for the district of Maryland, wherein the said George Westinghouse, Jr., and The Westinghouse Air Brake Company are 1395 complainants, and the said Boyden Power Brake Company, George A. Boyden, president, Charles B. Mann, secretary; William Whitridge, treasurer; and Boyden Brake Company, are defendants, a decree was entered on the 25th day of April, A. D. 1895, by the Hon. Thomas J. Morris, judge of the said court, against the said Boyden Power Brake Company, George A. Boyden, president; Charles B. Mann, secretary; William Whitridge, treasurer; and Boyden Brake Company, defendants, in favor of the said George Westinghouse, Jr., and The Westinghouse Air Brake Company, complainants, among other things, enjoining the said defendants as therein set forth; and, whereas, the said George Westinghouse, Jr., and the Westinghouse Air Brake Company have prayed an appeal from said decree to the United States circuit court of appeals for the said circuit, which said appeal has been allowed.

Now, therefore, if the said George Westinghouse, Jr., and the Westinghouse Air Brake Company shall well and duly prosecute the said appeal with effect, and shall answer to the said Boyden Power Brake Company, George A. Boyden, president; Charles B. Mann, secretary; William Whitridge, treasurer, and Boyden Brake Company all costs by the said Boyden Power Brake Company, George A. Boyden, president; Charles B. Mann, secretary; William Whitridge, treasurer, and Boyden Brake Company sustained, in case they, the said George Westinghouse, Jr., and the Westinghouse Air Brake Company shall fail to sustain their said appeal, then, and in such case, the above obligation is to be void, otherwise to be, and remain, in full force and effect.

GEO. WESTINGHOUSE, JR. [L. s.]

[Seal of Westinghouse Air Brake Company.]

THE WESTINGHOUSE AIR BRAKE CO.,

By H. H. WESTINGHOUSE, *General Manager.*

WM. J. C. DULANY. [L. s.]

1396 STATE OF PENNSYLVANIA, }
County of Allegheny, } ss :

Before me, the undersigned authority, hereunto duly authorized, personally appeared George Westinghouse, Jr., and H. H. Westinghouse, general manager of the Westinghouse Air Brake Company, obligors above named, who acknowledged the foregoing signature as their voluntary act, for the purposes and uses therein set forth.

Witness my hand and official seal this ninth day of May, A. D. 1895.

[SEAL OF NOTARY.]

[SEAL OF NOTARY.]

MURRAY HANSON,
Notary Public.

And now, to wit, May 13th, 1895, the within bond presented, approved and ordered to be filed.

THOS. J. MORRIS, Judge.

1397 Citation.

UNITED STATES OF AMERICA, }
District of Maryland, } ss :

To the Boyden Power Brake Company ; George A. Boyden, president ; Charles B. Mann, secretary ; William Whitridge, treasurer and Boyden Brake Company :

You are hereby cited and admonished to be and appear at a term of the circuit court of appeals of the United States in and for the fourth circuit, to be holden in the city of Richmond, State of Virginia, at the term of said court, on the 28th day of May, A. D. 1895 ; pursuant to an appeal filed in the clerk's office of the circuit court of the United States, wherein George Westinghouse, Jr., and The Westinghouse Air Brake Company are appellants, and you are the appellees, and show cause, if any there be, why the decree in said appeal mentioned should not be reversed or corrected, as regards so much and such parts of the said decree as contain or involve the refusal of an injunction under claims 1 and 4 of the patent in suit No. 360,070, as referred to in the bill of complaint thereon and speedy justice not be done to the parties in that behalf.

Witness, the Honorable Thomas J. Morris, judge of the said

circuit court of the United States, this 13th day of May, in the year of our Lord one thousand eight hundred and ninety-five.

[The Seal of the Circuit Court, Maryland.]

THOS. J. MORRIS, *Judge.*

Service of the within citation acknowledged this 13th day of May, 1895.

BARTON & WELMER,
Solicitors for Defendant.

1398 Thereupon, it is ordered by the court here that a transcript of the cross-appeal of the complainants in the cause aforesaid, together with all things thereunto relating, be transmitted to the said United States circuit court of appeals for the fourth circuit, and the same is transmitted accordingly.

Test:

JAS. W. CHEW, *Clerk.*

UNITED STATES OF AMERICA, } *To wit:*
District of Maryland, }

I, James W. Chew, clerk of the circuit court of the United States for the fourth circuit, in and for the district of Maryland, do hereby certify that the foregoing is a true transcript of the cross-appeal of the complainants, together with all things thereunto relating in the therein-entitled cause.

In testimony whereof, I hereunto set my hand and affix the seal of the said circuit court this 13th day of May, A. D. 1895.

JAS. W. CHEW,
Clerk of said Circuit Court.

1399 *Proceedings in the United States Circuit Court of Appeals, Fourth Circuit.*

United States Circuit Court of Appeals, Fourth Circuit.

BOYDEN POWER BRAKE COMPANY <i>et al.</i> , Appellants,	} No. 131. Appeal from the Circuit Court of the United States for the District of Maryland.
<i>vs.</i> WESTINGHOUSE AIR BRAKE COMPANY <i>et al.</i> , Appellees.	
WESTINGHOUSE AIR BRAKE COMPANY <i>et al.</i> , Appellants,	} No. 134. Cross-appeal from the Circuit Court of the United States for the District of Mary- land.
<i>vs.</i> BOYDEN POWER BRAKE COMPANY <i>et al.</i> , Appellees.	

April 17, 1895, petition of appellant- in No. 131, affidavit, and order of court thereon relating to filing printed records, was filed, to wit:

109—403

Petition, Affidavit, and Order of Court Relative to Filing Printed Records.

Filed April 17, 1895.

In the United States Circuit Court, District of Maryland.

GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE
AIR BRAKE COMPANY

vs.

BOYDEN POWER BRAKE COMPANY; G. A. BOYDEN,
President; C. B. MANN, Secretary; William Whit-
ridge, Treasurer.

In Equity.

To the honorable judges of the U. S. circuit court of appeals, fourth circuit :

In the above-entitled cause a decision was rendered on the 1400 11th day of March by U. S. circuit court, district of Maryland, in favor of the complainants, and, from which decision defendants have appealed.

Under rule 23 of the U. S. circuit court of appeals, the appellant is required to furnish the court with twenty copies of the complete printed record "unless a different order as to such printing is made by the court of its own motion or upon application."

The court is therefore petitioned for an order permitting the defendants—appellants on appeal—to file four copies of the complete printed record with the court. This number will provide each of the three judges with a copy and an additional one in case it is required. The complainants—appellees on appeal—will also be furnished with three copies as required by rule 23.

It is exceedingly important to the defendants that the appeal be heard in the May term, as an injunction has been granted restraining them from manufacturing the device in controversy.

It is impossible to reprint the complainants' record in time for the case to be heard in the May term, as their record consists of over 700 pages, and is extensively illustrated; to do so will require a great deal of time and labor and involve an expenditure of over one thousand dollars (\$1,000).

As the defendants—appellants on appeal—have eight copies of the complainants' record on hand, the record can be made up in time for the May term if the court will grant the desired order. A copy of the order is herewith enclosed.

And as in duty, &c.

SKIPWITH WILMER,
Of Counsel for Appellees.

UNITED STATES OF AMERICA, }
District of Maryland, } *To wit :*

Before the subscriber, a commissioner of the United States, in and for the district of Maryland, personally appeared in the said district

his 13th day of April, in the year eighteen hundred and ninety-five, George A. Boyden, president of the Boyden Brake Company of Baltimore City, and made oath on the Holy Evangelical of Almighty God that the matters and things stated in the foregoing petition are as therein set forth, to the best of his knowledge, information and belief, and subscribed the same.

G. A. BOYDEN.

[SEAL.] GEORGE MORRIS BOND,
United States Commissioner for the
District of Maryland.

1401 Ordered by this court this 17th day of April in the year eighteen hundred and ninety-five, on the foregoing petition and affidavit that the appellants be, and they are hereby permitted and authorized to file with the clerk four copies of the record for the use of the court and three for the use of counsel for the appellees, instead of twenty copies as required by rule 23, as prayed in the said petition.

N. GOFF.

May 7, 1895, the transcript of the record in No. 131 and six copies of the printed record was filed, and appearances of Skipwith Wilmer, Hector T. Fenton, and Lysander Hill were entered for the appellants.

May 9, 1895, appearances of Bernard Carter, J. Snowden Bell, and George H. Christy were entered for the appellees in No. 131.

May 14, 1895, the transcript of the record on cross-appeal (No. 134) was filed, and appearances of J. Snowden Bell, George H. Christy, and Bernard Carter were entered for the appellants.

May 16, 1895, appearances of Barton & Wilmer, Lysander Hill, and Hector T. Fenton were entered for the appellees in No. 134.

May 16, 1895, 16 copies of the printed record, together with the following petition of the appellants, were filed in No. 134.

Petition to file printed records on cross-appeal *nunc pro tunc* as of May 7, 1895.

Motion to File Record on Cross-appeal Nunc pro Tunc.

Filed May 16, 1895.

U. S. Circuit Court of Appeals, Fourth Circuit.

GEORGE WESTINGHOUSE, JR., and THE WEST-
INGHOUSE AIR BRAKE COMPANY

vs.

BOYDEN POWER BRAKE CO., GEORGE A. BOY-
den, Charles B. Mann, William Whitridge,
and Boyden Brake Co.

In Equity. No. 134.

1402 And now, to wit, May 16th, 1895, the complainants above named file this their motion that the printed records of their cross-appeal, filed herewith, may be ordered to be filed *nunc pro tunc*, as of May 7th, 1895,—to the end that both appeals may

come on together regularly for hearing under the rules—this motion being based on the following, among other facts:

1st. Decree was not entered till April 25th, 1895.

2nd. Original appeal was not taken until April 29th, 1895.

3rd. Complainants' counsel were not advised of any intention that the hearing thereof would be urged for the coming term, until they were served with the printed records, the latter though served formally on May 8th, not reaching them until May 10th.

4th. During the week next following the original appeal, complainants' counsel were necessarily engaged in preparing and arguing in the U. S. circuit court of appeals for the second circuit the appeal taken by the defendants from the decree of Judge Lacombe granting an injunction in *Westinghouse et al. v. New York Air Brake Company et al.* for infringement, *inter alia*, of the patent here in suit.

For these reasons, the delay was unavoidable, and this motion is made accordingly.

GEORGE H. CHRISTY,

For Complainants.

June 8, 1895, motion of appellees in open court in No. 134 to dismiss the cross-appeal.

June 10, 1895, motion of appellees in No. 134 to dismiss the cross-appeal was argued, and the motion was denied.

June 10, 1895 (May term, 1895), both causes came on to be heard on the transcripts of the record from the circuit court of the United States for the district of Maryland, and were argued together by counsel, and submitted.

At the November term, 1895, to wit: November 11, 1895, the court announced and filed its opinion, which is as follows, to wit:

Opinion.

United States Circuit Court of Appeals, Fourth Circuit.

BOYDEN POWER BRAKE COMPANY <i>et al.</i> , Appellants, <i>vs.</i> WESTINGHOUSE AIR BRAKE COMPANY <i>et al.</i> , Appellees.	}	No. 131. Appeal from the Circuit Court of the United States for the District of Maryland.
---	---	--

WESTINGHOUSE AIR BRAKE COMPANY <i>et al.</i> , Appellants, <i>vs.</i> BOYDEN POWER BRAKE COMPANY <i>et al.</i> , Appellees.	}	No. 134. Cross - appeal from the Circuit Court of the United States for the District of Mary- land.
---	---	---

(Causes argued together June 10, 1895.
Decided November 11, 1895.)

Before Goff and Simonton, circuit judges, and Hughes, district
judge.

Lysander Hill, Hector T. Fenton, for the Boyden Power Brake
Company, Skipwith Wilmer on the brief; George H. Christy,
Frederick H. Betts, for Westinghouse Air Brake Company, J.
Snowden Bell and Bernard Carter & Son on the brief.

Statement.

George Westinghouse, Jr., one of the complainants in this suit,
is the inventor of automatic air brakes for the slowing and stopping
of railroad trains. He has taken out patents for devices in this
connection to the number of some ten or twelve. Of these, the
patent now in suit is that numbered 360,970, issued March 29, 1887.

This device does not seem to have proved effectual for the
1404 special purposes for which it was designed, and he improved
it by a later one, patented to him on January 24, 1888, num-
bered 376,837, which is not in suit. These two devices, while pre-
serving the mechanism for the ordinary stopping of trains em-
braced in earlier patents, contained additional mechanism for their
prompt and complete stoppage in sudden emergencies. The ap-
paratus as thus devised and improved are technically called quick-
action brakes, and are embraced in the patents 360,970 and 376,837.

Of the air brakes patented by Westinghouse previously to the
issuing of the two patents just named, the latest improvements were
embraced in the patent numbered 220,556, issued October 14, 1879.
In speaking of this latter patent we shall, except when special men-
tion of previous ones will be necessary, include generically all the
improvements embodied severally in its predecessors. This air
brake 220,556, though intended for both ordinary work and emer-

gency work, proved to be really effective only for the ordinary slowing and stopping of trains, and not to answer for the sudden stoppage of very long trains of cars. But it contained the auxiliary reservoirs and other apparatus which gave the brakes an automatic action. These three patents, numbers 220,556, 360,070 and 376,837, are those which enter most directly into the consideration of the case before us.

It is true that the patent of Westinghouse, number 168,359, is mentioned in complainants' bill of complaint, and not number 220,556; but in the briefs and in most of the testimony number 220,556 is made the prominent subject of discussion, and not number 168,359. There was an intermediate patent, number 217,838, which enters more or less into the polemics of this controversy; inasmuch as that patent, as well as number 220,556, already mentioned, were the immediate bases on which the quick-action brake, number 360,070 was founded.

In the earlier stages of the development of the Westinghouse air brake, it consisted of the following parts: First, a compressing air pump on the engine by which air was compressed to the density of eighty pounds to the square inch; second, a large reservoir for storing the compressed air fixed on the engine; third, a train-pipe or main pipe leading from the engine to and along all the cars of the train, connected at each interval between the cars by a flexible hose with couplings rendering the train-pipe continuous and constituting it a conduit for transmitting compressed air from the engine to every car; and fourth, a brake-cylinder on each car, connected by a branch pipe to the train-pipe, and chargeable with
1405 compressed air through the train-pipe from the storage reservoir on the engine—this brake-cylinder operating, by means of suitable levers, upon the brake-shoes which clasped the wheels of each car.

Useful as this system of braking proved to be, it was found not to meet all the requirements of the service. In the transmission of compressed air from the engine an appreciable loss of time was found to occur. This loss proved to be about one second per car; so that on a passenger train of ten cars the time necessary for the pressure to reach the rear car would be ten seconds; and on a freight train of fifty cars would be nearly a minute. Thus, while the forward movement of the foremost cars would be checked at once, that of the rearmost cars would not be as promptly checked, and these would come against the cars in front of them with more or less shock, producing more or less discomfort or positive damage. This defect will be appreciated when it is remembered that a train moving at the rate of forty-five miles an hour moves sixty-six feet per second; so that, a freight train of fifty cars would run more than half a mile before the brakes could begin to be effective along the entire train. This defective system contained but one reservoir for holding the compressed air, which, as before stated, was attached to the engine, and from which all the brake-cylinders of the several cars had to be charged back through the train-pipe and its branches and couplings.

It was incumbent upon the inventor, therefore, to devise a remedy for this defect in the earliest forms of his air brakes. He supplied it by providing an auxiliary reservoir for compressed air on each car; and also by devising a mechanism for discharging compressed air from this auxiliary reservoir into the brake-cylinder of its own car; so that as soon as the engineer put in action his mechanism for checking or stopping the train, there was a more nearly simultaneous action of the brake-cylinders along the whole train upon the series of brakes provided for each car.

The mechanism devised for this purpose was what is known in the art as the triple valve; one of which was provided for each car, and acted upon each brake-cylinder with compressed air drawn from each auxiliary reservoir. It was called a triple valve because one of its valves controlled the passage between the train-pipe leading from the engine and the auxiliary reservoir; another between the auxiliary reservoir and brake-cylinder belonging to each car, and a third between the brake-cylinder of each car and the atmosphere. It was located at the junction of the three pipes which lead from and to each of these devices. The triple valve has three ports leading, respectively, to the three devices named, and also a fourth one leading to the open air.

1406 A very important feature of the Westinghouse triple-valve mechanism consisted in its being automatic in operation. It is not in our province to enter into details, suffice it to say that when the train is in use all the apparatus which has been described is kept constantly charged in full with compressed air generally to the density of seventy pounds to the inch, which has continuous and unobstructed flow from the main reservoir on the engine to all the auxiliary reservoirs on the cars. While the apparatus is thus full charged from the engine, through the train-pipe to the auxiliary reservoirs, the piston of each triple valve is held to its normal position with the port between the auxiliary reservoir and brake-cylinder closed, there being an equipoise of pressure on each side of it. It follows that whenever the pressure of the air on the train-pipe side of the piston is reduced, the piston moves out into its chamber and thereby opens a passage for the compressed air from each auxiliary reservoir into each brake-cylinder, resulting automatically in an application of the brakes. This reduction of pressure in the train-pipe has the result described, whether it is caused by the engineer in intentionally opening his valve for the purpose, or by an accident which may produce a rupture in any part of the train-pipe. Such action of the engineer, or such accident, opens the train-pipe for the escape of pressure from that side of each triple-valve piston, causes the piston to move forward in its chamber, and thereby to open a passage for discharging compressed air from the auxiliary reservoir to the brake cylinder for action upon the brakes. This *automatic* action was a very important achievement, and gave to the air brake of Westinghouse a part of its name.

Before this invention the brake-cylinders were charged directly from the engine by forcing the compressed air backward into them, along the entire length of the train. In the triple-valve device the

air movement was reversed. While the train is running, all the apparatus, except the brake-cylinders, is full of air of the density of seventy pounds, stored distributively in the several auxiliary reservoirs. The engineer operates by opening his valve on the engine for the escape of train-pipe air, which thereby takes a course the reverse of the former, from the rearmost car and moving forward along all the cars to its escape at the engineers' valve.

Thus before the invention of the improved device patented in No. 217,838, when the engineer desired to apply his brakes with full force, he operated the valve at the engine and opened the port wide, letting the compressed air out of the train-pipe at the 1407 locomotive, then its only vent. The air, as before said, had to travel from the rear car along all the cars, forward to the engine, before it could lessen the pressure of the train-pipe air on the train-pipe side of the chamber of each triple-valve piston, and before the brake-cylinders could be operated with air from the auxiliary reservoirs. In a train of fifty cars it would have to travel nearly half a mile to get out at the engine. Westinghouse devised in patent 217,838 a means of quickly emptying the train-pipe by providing release valves on each car connected directly with the train-pipe; so that the air of the train-pipe could be vented promptly at each car, and thus shorten the time of bringing all the brakes along the whole train into action.

But while the triple valve and other mechanism patented in number 217,838 and number 220,556 was intended to accomplish the purpose of producing simultaneous action by the brakes in every car, and thus to prevent, in a great measure, the jostling of cars against each other, thereby securing a comparatively steady, smooth, uniform arrest of movement along the whole train; yet it was found to be effective for this purpose in very long freight trains only on ordinary occasions, such as the stopping of trains at stations, or slowing them at side tracks, or holding their speed in check on descending grades. The mechanism of the patents just named did not provide effectively for sudden emergencies, and therefore failed to meet a great necessity of the service.

It is true that the design of the inventor was to devise in these patents an apparatus that would be effective for both the gradual and the sudden stoppage of trains. For the former purpose he inserted a sensitive valve on the stem of the triple-valve piston of 220,556 by which, on a partial movement of the piston in its chamber, a graduated discharge of air from the auxiliary reservoir into the brake-cylinder was effected. For the latter purpose, the sudden stoppage of trains, he provided a main valve at the end of the stem of the piston by which, on a complete traverse by the triple-valve piston in its chamber, a large venting of compressed air from the auxiliary reservoir was effected, so that, in the language of one of the Westinghouse witnesses, "if an emergency arises demanding that the brakes be instantly applied with full force to effect a sudden stoppage of the train, the pressure of air is suddenly and considerably or entirely reduced in the train-pipe with the result that the piston of the triple valve makes its full stroke, * * * per-

mitting auxiliary reservoir air to flow directly into the brake-cylinder, * * * (making what is known as) the emergency stop."

1408 The inventor, however, failed in this latter object. It was found in practice on long trains that the air from the auxiliary reservoir did not act with sufficient promptitude on the brakes of the rear cars for emergency purposes, and that it would be necessary to devise some other means for effecting a quick action of the brake-cylinder. Patent 168,359, repeated in patent 220,556, was a most valuable invention. It had great utility. It produced a uniform stoppage of the cars of long trains on ordinary occasions, and on short trains, whether passenger or freight, it was practically effective even for emergency purposes. Yet for the sudden stoppage of long trains in the face of immediate danger it failed to answer the requirements of the service. As one of the counsel of Westinghouse expressed it in his oral argument before this court: "A passenger train or a freight train of moderate length, and, therefore, of moderate weight, could be stopped, as is shown by the proofs, by the old automatic brake (patent 220,556) within reasonable limits of distance of space and lapse of time; but the railroad conditions of the country and the system of traffic altering, by which large locomotives drawing heavy and long trains came into use, a new development in the art was called for; that is, for a brake which would act quicker on any car, and act quicker from car to car, than any which had previously existed."

With this brake of patent 220,556, gradual stopping and slowing was executed by giving the piston a partial or half traverse on its chamber by which air passed through the sensitive valve on the stem of the piston to the brake-cylinder; and emergency stopping was done by a full or extreme traverse of the piston in its chamber which closed the sensitive valve in its stem and opened the main valve fixed upon the end of the stem, and allowed a full and direct venting of air from the auxiliary reservoir into the brake-cylinder. The best illustrations available for the better understanding of the preceding remarks are the diagrams that are found opposite pages 20 and 21 of the main brief of the appellants. (Boyden.)

It is obvious from what has been said that the piston of the triple valves is a most prominent instrumentality in the present controversy. The brakes are operated by the engineer from the engine. The engineer's duty in connection with them is, first, to keep his apparatus full charged with compressed air whenever the train is in use, and, second, when the occasion requires, to let off air from the train-pipe, and thereby cause, in the manner heretofore described, the escape of more or less air from the auxiliary reservoirs into the brake-cylinders for action upon the brakes. The

1409 mechanism is such, also, as before stated, that an escape of compressed air from the train-pipe results not merely from the intentional action of the engineer himself, but automatically from any accident that may happen to cause a severance of the train into parts, or a rupture of the train-pipe or its connecting hose or branches. It is the escape or venting of compressed air,

either intentional or accidental, from the auxiliary reservoirs in which it is stored, into the brake-cylinders, that operates the brakes and this venting is done through the triple valves by means, as heretofore stated, of the triple-valve pistons.

In the Westinghouse automatic air brake, as patented in number 220,556, the ordinary work of braking was performed by a partial traverse of its chamber by triple-valve piston, graduated, according to the purpose desired, at the will of the engineer; and emergency work was done by an extreme traverse of the piston to the end of its chamber. It may be observed that the automatic air brake patented as number 220,556, which embraced all previous improvements, is now free to public use, the patent having expired and ceased to be confined to the exclusive use of its inventor.

A study of patent 220,556 will show that compressed air driven by the engineer into the train-pipe, passed through the triple valve of each car to its auxiliary reservoir; that there was no vent from this train-pipe air into the brake-cylinder, except through the auxiliary reservoir, and that this vent from the auxiliary reservoir to the brake-cylinder ordinarily occurred when the triple-valve piston had made but a partial movement or traverse in its chamber. The text and diagram of 220,556 show that even a full or extreme traverse of the piston in its chamber would vent no other compressed air into the brake-cylinders, except from the auxiliary reservoirs.

The device embraced in patent 220,556, valuable and efficient as it is and was for ordinary work on all trains, with the triple-valve piston in partial traverse, and for emergency work on short trains with the triple-valve piston in extreme traverse; yet it failed to meet the requirements of the service for emergency work on long trains of fifty large freight cars. For the latter work it was found insufficient in practice, the insufficiency consisting in not acting with sufficient promptitude. It is not for us to explain why the passage of compressed air exclusively from the auxiliary reservoir to the brake-cylinders was not sufficiently prompt on long freight trains. It is assumed in the briefs and testimony that the mechanism of this patent did not suffice for this work. It is admitted on both sides that while the mechanism of 220,556, though effective for the ordinary purposes of braking trains such as stopping them at stations, slowing them in passing switches and other points requiring continuous movement, and checking them on descending grades, yet that it was not effective for abruptly stopping long trains in sudden emergencies.

This deficiency of the Westinghouse brake in the stage of improvement which it had reached in patent 220,556, from whatever cause resulting, created the necessity for some additional invention by which, on sudden emergencies in the presence of immediate danger, a long train of cars in rapid motion should be immediately brought to an abrupt stoppage by an instantaneous and simultaneous application of all the brakes of every car. The thing wanted was what has technically come to be called "quick action."

Each of the chief contestants in the present suit set himself laudably to work in deriving a means to accomplish this important

desideratum, each taking the air brake, patented as number 220,556, Westinghouse's exclusive property in which has expired, as the basis of his new device, the common object being to produce a mechanism by which to secure instantaneously, whenever and only when a sudden emergency arose, such a quickened discharge of compressed air into the several brake-cylinders that each car would simultaneously, and the entire train as a whole, be brought to a sudden halt, but leaving all the mechanism already existing for use in ordinary braking unmolested and unchanged.

Counsel for appellees (Westinghouse) in his oral argument well described the need that was to be supplied when he said: "Quick action does not involve greater *power* of the brake; it is not a question of greater force of brake, as applied to the brake-shoes of any individual car. The force with which the brak'-shoes are applied to any individual car is no greater with the Westinghouse quick-action brake (360,070), which is in controversy here, than it was with the old automatic brake (220,556). The engineer is, in both cases, operating with seventy pounds of pressure in the main reservoir on the locomotive and in the auxiliary reservoirs on the cars throughout the train, and in the system of pipes throughout the train, and all the force he can possibly apply with the present quick-action brake (360,070), or with the old automatic brake (220,556), is seventy pounds of pressure to the piston of the brake-cylinder, and through it to the brake-shoes."

And the same counsel well described the desideratum sought for—the gist of the urgent need—when he said that its characteristic must be "the utilization of auxiliary reservoir pressure for service or for graduation, when you do not need to use quick action; but when you want to get what is known in the art as *quick-action*, when the question of life or death is to be settled in a few seconds, then the pressure from the *train-pipe*, (which comes from the main reservoir on the locomotive,) is to be utilized for that purpose."

Westinghouse devised for each car an additional valve, which he so attached to the triple valve of patent 220,556 that when the piston should be in complete traverse and driven to the end of its chamber, it should drive forward an additional stem provided for this additional valve, and thereby open a port in that valve by which compressed air from the train-pipe should pass, through by-passes independent of the triple valve, into the brake-cylinder into which the triple valve vented compressed air from the auxiliary reservoir. By this device of the additional stem, the additional valve and the independent by-passes into which the latter opened, the inventor contrived to discharge compressed air from both the auxiliary reservoir and the train-pipe into the brake-cylinder of each car simultaneously, and thereby so quickened the action of the brakes as to accomplish the desideratum of *quick action*. To repeat, his device for this purpose consisting in attaching to the pre-existing triple valve, as patented in number 220,556, a machine which embraced an additional stem, an additional valve and additional air passages leading from the port in the new valve to the brake-cylinder. This

new attachment is put into action for emergency purposes by the triple-valve piston when on its extreme transverse. The previous machine 220,556 had provided for the extreme traverse of the piston by which it had put in action the main valve at the end of its old stem, and opened a full and direct flow of compressed air from the auxiliary reservoir into the brake-cylinder for the use in emergencies. Thus the new contrivance, by the same extreme traverse of the triple-valve piston, continued the old flow of compressed air for emergency purposes and provided an additional flow of the air for emergency purposes by an additional mechanism; the latter flow being directly from the train-pipe, and the former flow being from the auxiliary reservoir. Such was the make-up of patent 360,070—two machines in one box or case. It was found, on thorough and conspicuous trials, to be imperfect and inefficient, and lacked that essential element of patented devices—utility. But it contained a valuable invention, and was afterwards to improved details, when patented in number 376,837, as to become 1412 machine of great value to the public, a supplemental piston being supplied in 376,837.

Boyden also made a successful invention of venting compressed air from the train-pipe into the brake-cylinder of each car simultaneously with venting air from the auxiliary reservoir to the brake-cylinder, as had been done for emergency purposes by the previous triple valve of patent 220,556. He did not resort to a second machine. He — not devise an additional stem, an additional valve or by-passages independent of those of the triple valve. He accomplished the transmission of compressed air directly from the train-pipe to the brake-cylinder by other means. He inserted a partition in the form of a brass ring into the triple valve of patent 220,556 itself, between the chamber containing the valves and the compressed air of the auxiliary reservoir on one hand and the chamber of the piston containing train-pipe air on the other, and he opened a port in that partition for the passage of compressed air from the train-pipe to the brake-cylinder. He thereby so provided that where Westinghouse's device employed a fourth valve, another stem and newly contrived by-passages for discharging compressed air from the train-pipe into the brake-cylinder, organized separately in a second machine; Boyden contrived to discharge both train-pipe and auxiliary reservoir air simultaneously into the brake-cylinder without using an additional stem or valve or by-passages. The devices of Westinghouse and Boyden are exhibited by the diagram on the sheet inserted between pages 34 and 35 of appellant's (Boyden) principal brief, and is attached to this statement. Let these diagrams be made a part of this opinion.

(Here follow diagrams marked pp. 1413 & 1414.)

It is not for us to describe how the introduction of train-pipe air into the brake-cylinder of each car quickens the action of the brakes which are already subject to the action of air from the auxiliary reservoir. It is sufficient to say that the engineer, by means of

valve on the engine and by means of the branch pipe leading from the train-pipe to the triple valve of each car, can, by the improvements in controversy, vent the air of the train-pipe directly and more promptly into the brake-cylinder, and thus more quickly apply the brakes, than he can by the indirect conduit opened by the main valve of 220,556 into the brake-cylinder from the auxiliary reservoir when its piston is in extreme traverse, as heretofore described. Quick action being the desideratum, the engineer effects it more promptly by the direct means than by the indirect.

1415

Opinion.

HUGHES, J. :

The foregoing statement of facts and explanation of the devices upon which the decision of this case depends is of unusual length, which has been a necessary result of the extraordinary magnitude of the record and the unusual number and volume of the briefs of counsel in the case ; but it has been prepared at the expense of very much labor, and is, we trust, *we trust*, sufficiently correct to warrant the conclusions of law of which we have founded upon them.

Of the technical "claims" set out by Westinghouse in his application for the patent, number 360,070, those numbered 1, 2 and 4 are the special subjects of this suit. The device described in these claims is the one which Westinghouse charges in the bill of complaint in this case to have been infringed by the Boyden invention. The three "claims" are as follows, and the words in italics indicate the device charged to have been infringed :

" 1. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, a triple valve, and an *auxiliary-valve device, actuated by the piston of the triple valve and independent of the main valve thereof, for admitting air in the application of the brake, directly from the main air pipe to the brake-cylinder, substantially as set forth.*

" 2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, *and which by a further traverse admits air directly from the main air pipe to the brake-cylinder, substantially as set forth.*

" 4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, *and an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake cylinder, respectively, substantially as set forth.*"

The phrase "substantially as set forth" is technical, and is equivalent to saying "by the means described in the text of the in-

ventor's application for letters patent, as illustrated by the
 1416 drawings, diagrams, and models which accompany the application." These words limit the general terms of the specification which set out the *function* performed by the invention, and confine the inventor's rights to his own *means* or their mechanical equivalent of performing the function.

It is unnecessary to set in *totidem verbis* the technical "claims" in which Boyden summarized his application to the Patent Office. Suffice it to say, that his device, original and improved, which is represented in the patents issued to him as numbers 481,134, 481,135, and 481,136, dated August 16, 1892, provided for the admission by a single valve, integral with the triple valve, of both train-pipe air and auxiliary reservoir air to the brake-cylinder for emergency stops. He accomplished this object as Westinghouse did, by a device acted upon by the triple-valve piston when at the same extreme traverse at which it had been previously used for emergency work. As to using this extreme traverse, described in the patent which expired, number 220,556, he did what Westinghouse did; but the object of either being the discharge of train-pipe air into the brake-cylinder (which was new) simultaneously with the discharge of auxiliary reservoir air into that cylinder (which was old), Boyden invented a partitioning ring in the old triple valve to divide the chamber of the three valves from the chamber of the piston, and opened in this ring a port through which the train-pipe air might pass from the piston chamber through the chamber of the valves to the brake-cylinder; while Westinghouse attached an additional individual machine to patent 220,556, consisting of a stem moved by the main piston in extreme traverse, an additional valve, and additional independent by-passages leading from the additional valve to the brake-cylinder. The same *result* was accomplished by the two devices, but these had but one means in common. Each used one common mechanical movement of the main piston, which was a movement described in the patent which has expired. But the further mechanism employed, respectively, by the two inventions were, respectively, as has been described.

The transmission of train-pipe air and auxiliary reservoir air simultaneously to the brake-cylinder is a *result* of function and is not patentable. The *means* by which this or any other result or function is accomplished may be many and various, and if these several means are not mechanical equivalents, each of them is patentable. The question at bar is, whether Boyden's brass-ring partition with the port it contains, inserted in and made a part
 of the triple valve itself, successfully accomplishing the
 1417 function of discharging train-pipe air into the brake-cylinder simultaneously with the triple valve's discharge of auxiliary reservoir air into that cylinder, is the mechanical equivalent of Westinghouse's attached machine, non-integral, segregate and individual, consisting of another stem, another valve, and by-passages peculiar to itself leading from the additional valve to the brake-cylinder; both devices being put in action by the triple-valve piston when on its old extreme traverse.

This question was presented necessarily to the Patent Office of the United States when Boyden applied for a patent for the device under consideration. That office employs the best experts in mechanics which it can secure in this and other countries. Its examinations are indeed *ex parte* in form, but they are, nevertheless, conducted under hot and skilled contestation in every case of importance, and its decisions, though not conclusive, are entitled to great respect. That office, after full examination, awarded a patent to Boyden on the 16th day of August, 1892, for his quick-action improvement on the device of patent 220,556, and that action by the office was, in effect, a ruling that the Boyden device did not infringe Westinghouse's quick-action patent number 360,070. That ruling takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics. That ruling was subsequent to the issuing to Westinghouse of both the patents, numbers 360,070 and 376,837, four years after the latter patent, when the Patent Office had full knowledge of them.

The circuit — held, in its decision of this case, that the Boyden device was the functional equivalent of that of Westinghouse, as described in claim 2 of patent 360,070; that both devices depended upon the extreme traverse of the triple-valve piston of patent 220,556, and that this traverse was new and unusual. It held virtually that the novelty of this extreme traverse, on which both the quick-action devices of the two inventions depended, and their functional equivalency made Boyden's device an infringement of Westinghouse's. That the mechanism of Boyden differed from that of Westinghouse, so far as the mechanical means which was used in availing of the extreme traverse was concerned, does not seem to have been controverted by the circuit court. But it held, virtually, that because the extreme traverse was new and was a pioneer invention of Westinghouse and was necessary to put both of the two devices into action, and because the means devised for utilizing the extreme traverse in emergency work were functional equivalents of Westinghouse's: therefore Boyden's device was an infringement.

1418 It is obvious to us that the circuit court erred in interpreting the patent in suit by imputing novelty to the extreme traverse of the triple-valve piston, because this was shown in the prior patent 220,556 and its predecessor, 168,359. That machine, 220,556, was designed both for graduated braking and for emergency braking. The former was provided in the sensitive valve inserted in the stem of the triple-valve piston, through which compressed air was vented, in quantity graduated at the will of the engineer, from the auxiliary reservoir into the brake-cylinder. But this earlier and expired patent contained more than the sensitive valve in the stem of the piston, and more room in the piston chamber than was necessary for a partial traverse of the piston. It contained a main valve and a sufficient prolongation of the piston chamber for the extreme traverse. This main valve and this prolongation of the chamber were entirely useless for graduated work, and was intended and employable only for emergency work. The

main valve would not have been contrived nor the chamber prolonged except for the purpose, by giving the piston its extreme traverse in the extended chamber, and thus bringing the main valve into action, of fitting it for emergency work. The machine patented as Nos. 168,359 and 220,556 did good emergency work in short trains, and the extreme traverse of the piston was constantly employed in that work; and this employment of it was not "unusual." But in long trains, and especially in long trains of heavy freight cars, it failed to do emergency work with sufficient quickness. The emergency apparatus, however, was there, to wit: the main valve and the extended chamber. They had been patented, and the patent has expired. The extreme traverse of the piston in its extended chamber for emergency use, was as old as the expired patent, No. 220,556. The circuit court, therefore, erred in supposing and ruling that it was new and unusual.

As there was no novelty in the extreme traverse of the old triple-valve piston it must be eliminated from consideration, and the mechanical equivalency of Boyden's device of the partitioning ring integral with the triple valve itself on one hand, and on the other hand the Westinghouse device attached to the triple valve, and consisting wholly of apparatus not integral, but segregate, individual, several, additional to and independent of it—depends upon the character of the two devices themselves, considered and compared apart from the extreme traverse, and not upon their being put into action by the extreme traverse of the triple-valve piston. Comparing the two devices apart from the triple-valve piston in 1419 extreme traverse, we are unable to entertain a doubt that the ruling of the Patent Office was correct to the effect that Boyden's device was not the mechanical equivalent of that of Westinghouse. They seem to us to differ as widely from each other as two devices for accomplishing the same result can well differ.

We think that when claim 2 of 360,070, in its language describing the action of that device, failed to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston, "by a further traverse, admits air directly from the main air pipe to the brake-cylinder," it was fatally defective, claiming only a result which is public property and not identifying the specific means (his own property) by which the result is achieved.

That this invention of Westinghouse, thus undefined, is one of the highest value to the public, and that — is a pioneer one in the art of quick-action air-brakes is not denied, and is conceded. It is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal protection from the courts in construing the claim. But there is a limit to the judicial liberality in this direction. If an inventor is ambiguous or obscure, or halt or limp in his language of description, the courts will help him out and so construe the claim as to give distinct identity to his device. If there be a doubt in the mind of the court or of a jury on the issue of mechanical equivalency, the court will give, and instruct the jury to give, the benefit of the doubt to the pioneer inventor. But where the inventor falls so far short in his description as to claim only the

result which his machine accomplishes, and omits an explicit definition of the *means* by which he does it, as in the case at bar, the courts have another duty to perform, one which they owe to the public and to the worthy fraternity of inventors, and must decline to give him general rights where he is entitled only to special rights.

The inventor in the present case seemed himself to feel that his claim was too broad in terms. In his original application for patent 360,070 his first claim was couched in this language: "In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve provided with a device for admitting air directly from the main air pipe to the brake-cylinder." This language covered *any device* which might accomplish the object mentioned, and he found it necessary to erase it from his specification, and to substitute claim 1 as it now stands.

In the same specification Westinghouse had also used this language: "Further, while in the specific construction described and shown, the function of admitting air from the main pipe is performed by a valve *separate* from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve *integral* with the main valve and formed by an extension thereof, would be included in and embody the essential operative features of my invention." Here again was a claim for a function irrespective of the mechanical means used in accomplishing it, which the inventor found it necessary to erase from his specification. In the suit at bar he virtually asks the court to restore to his claim the two erasures which he felt himself unable to sustain at the Patent Office. Our duty to the public and to inventors at large forbids our doing so.

Some notice is proper, in this connection, of the contention of appellees (Westinghouse), that the additional valve, four, in the additional stem of the quick-action apparatus attached to the original triple valve 220,556, by Westinghouse in patent 360,070, is the mechanical equivalent of the poppet valve of Boyden which he designates as 22 in the triple valve of 220,556 as he improves it in his device. This contention is urged on the ground, as alleged, that Boyden makes it perform the same purpose which Westinghouse's fourth valve performs in his attached apparatus. But Boyden simply substituted in the original triple valve his poppet valve 22 for the slide-valve which is the main valve of patent 220,556. Boyden's is not an "auxiliary" valve; it is mechanically the original main valve of the original triple valve, and it performs the service which is performed by the main valve of 220,556. It is not the mechanical equivalent of valve four in the attached apparatus of Westinghouse simply by reason of its taking part in an emergency service in admitting train-pipe air into the brake-cylinder. In the original triple valve it performed no other service than admitting auxiliary reservoir air into the brake-cylinder; in Boyden's device it continues to perform that service, and is made incidentally instrumental in allowing the passage of train-pipe air. The performance incidentally of quick-action service does not make it an auxiliary valve. It

is the same valve. The incidental *service* is auxiliary, but the valve itself is the same and unchanged. We think the circuit court was correct in its view that the poppet valve 22 of Boyden is the original main valve of 220,556.

We think the circuit court was correct in ruling that Boyden's invention under consideration does not infringe claim 1 of Westinghouse. The language of that claim, in defining the additional apparatus of Westinghouse embraced in patent 1421 360,070, is, "and an auxiliary-valve device, actuated by the piston of the triple valve and independent of the main valve" for admitting air directly from the train-pipe to the brake-cylinder. Obviously there is no "auxiliary valve" "independent of the main valve" in the Boyden device, and, we think, the ruling was correct. The case is similar in respect to claim 4 of Westinghouse. The language there is, "and an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake-cylinder." None of these terms can be fairly applied to the Boyden device or to any of its details; and we think that the circuit court ruled correctly in holding that claim 4 is not infringed by Boyden.

The distinction suggested by the circuit court between inventions employing cranks and levers visible to the senses, and those employing compressed air which operates by modes not visible to the senses,—as to which latter devices, the circuit court held that "in judging of an infringement we are to direct our attention rather to functional equivalents than to mechanical equivalents,"—we do not think well taken even in favor of pioneer inventions. The Supreme Court in its ruling in the great leading case of *O'Reilly v. Morse*, 15 Howard, 62, which was one in which the far more subtle agency of electricity was under consideration, neither made nor intimated such a distinction.

As to the adjudications in the Federal courts of the southern district of New York, on the subject of the air brakes invented by Westinghouse, it is incumbent upon us to consider whether the questions now before this court are in any respect *res judicata* and binding precedents in the case at bar. Technically they are not. The patent charged to have been infringed, in the first suit in the circuit court of New York, and on appeal in the appellate court of that circuit, was that taken out by Westinghouse, as number 376,837. That patent contained an important, indeed a vital, improvement upon number 360,070, which is in suit here, and which was found in practice to be insufficient for its purposes. It contained a supplemental or auxiliary piston, as well as an additional stem, an additional valve, and independent by-passes, composing an additional segregate machine, as we have before mentioned. In the second suit before the New York circuit and appellate courts, the parties complainant and defendant being the same and the defendant's invention being substantially the same, suit was based upon two patents of Westinghouse, numbers 360,070 and 376,837, and also upon a patent issued to H. S. Park, numbered 393,784. 1422 The question in both suits was, whether the air brake con-

BLEED. THROUGH POOR COPY

NEW YORK AIR BRAKE CO'S VALVE.

Decreed by Judge Lacombe to Infringe Patent No. 360,070, because it contains the "additional members" of that Patent.

The upper part of the mechanism in the above cut (colored blue) constitutes the "triple valve;" said parts are numbered 10, 11, 12, 14, 20, 36, 39 and 51.

The lower part (colored red,) infringes the Westinghouse invention because it includes the "additional members," a separate "auxiliary valve 41" and passage 46, leading from the train-pipe direct to the brake-cylinder.

It will be seen the above structure has the "two machines," the blue and the red the same as Patent 360,070, whereas Defendants' Structure Plate XI here in suit, has only one—the blue, and—therefore is minus the "additional members."

trived by the defendant in those suits had infringed the three patents. Judge Lacombe, who was affirmed on appeal, described the machine of the defendant there as having "the main air pipe (train-pipe), an auxiliary reservoir, a brake-cylinder, a triple valve"—the latter being the old triple-valve mechanism of patent 220,556, "and an auxiliary-valve device, independent of the main valve, for admitting air in the application of the brake directly from the main air pipe to the brake-cylinder." A diagram which illustrates this additional and "auxiliary-valve device, independent of the main valve" of the defendant in the New York suits, is given in the second brief or "oral argument" for appellants (Boyden) here, opposite page 36, and is attached to and made a part of this opinion.

(Here follows diagram marked p. 1423.)

It will be apparent, from an inspection of this diagram, that no decision affecting that device can effect one as different from it structurally and in every respect as is that of the Boyden device. It would require the verdict of a jury and the conclusive testimony of experts upon the question of mechanical equivalency to enable a court to decide whether they present a case of *res judicata*.

Prima facie, a decision founded upon one patent not in suit here, and another decision founded upon three patents collectively, one only of which is in suit here, the two decisions declaring that an invention used by a defendant who is not the defendant here, against the machine of that defendant differing widely in its structure from the one complained of here, cannot be treated as binding in the decision which this court may feel bound to render in the suit at bar.

Here it is contended that the mere use of the extreme traverse of the triple-valve piston to effect the same *functional* result, which was effected by Westinghouse in 360,070, constitutes an infringement, irrespectively of the additional means employed. There it was ruled that the use of the extreme traverse *and* of an additional machine attached to the original 220,556, which was structurally and *mechanically* equivalent to 360,070, was an infringement of the latter patent. The cases are different and not on all-fours with each other, and do not control or affect our own ruling.

Decrees will be entered, in accordance with the views expressed in this opinion, affirming the ruling of the court below in respect to claims *one* and *four* of the complainant's patent, number 360,077, and reversing the ruling of the court below in respect to claim *two* of the said patent.

1424 At the same term, to wit: November 11, 1895, the court here made and entered the following decree, to wit:

Decree.

United States Circuit Court of Appeals, Fourth Circuit.

BOYDEN POWER BRAKE COMPANY <i>et al.</i> , Appel-	}	Nos. 131 and 134.
lants,		
<i>vs.</i>		
WESTINGHOUSE AIR BRAKE COMPANY <i>et al.</i> ,		
Appellees,

WESTINGHOUSE AIR BRAKE COMPANY <i>et al.</i> ,	}	
Appellants,		
<i>vs.</i>		
BOYDEN POWER BRAKE COMPANY <i>et al.</i> , Appel-		
lees.		

Appeal and cross-appeal from the circuit court of the United States for the district of Maryland.

This cause came on to be heard on the transcript of the record from the circuit court of the United States for the district of Maryland, and was argued by counsel.

On consideration whereof, it is now here ordered, adjudged, and decreed by this court, that the decree of the said circuit court, in this cause, be, and the same is hereby, affirmed with respect to claims one and four of the complainant's patent number 360,-70, and reversed with respect to claim two of the said patent. And this cause is remanded to the circuit court of the United States for the district of Maryland with direction to enter a decree therein in conformity with the opinion and decree of this court. Costs in this court to be paid by Westinghouse Air Brake Company.

It is further ordered that the mandate of this court issue after the expiration of twenty days from the date hereof.

CHARLES H. SIMONTON,
Circuit Judge.

November 11th, 1895.

1425

Petition to Stay Mandate.

Filed November 25, 1895.

United States Circuit Court of Appeals, Fourth Circuit.

BOYDEN POWER-BRAKE COMPANY <i>et al.</i> ,	}	No. 131. Appeal from the Circuit Court of the United States for the District of Mary- land.

<i>al.</i> , Appellants,		
<i>vs.</i>		
BOYDEN POWER-BRAKE COMPANY <i>et al.</i> ,	}	
Appellees.		

Motion for stay of mandate.

And now, to wit, come The Westinghouse Air Brake Company and George Westinghouse, Jr., appellees in cause No. 131, and appellants in cause No. 134, by George H. Christy, their counsel, and move the court that the mandates in said causes be stayed for such time as to the court may seem meet, to the end that the said movers herein may, before the issue of such mandates, have time to prepare and present to the supreme court their petition for a writ of *certiorari* therein, with reasonable allowance of time for the action of said court thereon.

And said counsel hereby certifies to the court that no injunction was issued against defendants from the court below, so that the defendants are not now and have not been under injunction at any time herein—this fact having also been stated and admitted in open court at the hearing in this court.

GEORGE H. CHRISTY,
Att'y for Westinghouse Air Brake Co.
and George Westinghouse, Jr.

Pittsburg, Pa., Nov. 23, '95.

BOYDEN POWER-BRAKE COMPANY <i>et al.</i> ,	}	
Appellees.		

To the Hon. Nathan Goff, justice of the cir. ct. of appeals for the fourth circuit.

SIR: We desire to appear before your honor, by counsel, for the purpose of opposing the motion made by Westinghouse for a stay of mandate in the above-entitled cause.

We suggest that Wednesday, December 4th, 1895, would be a convenient day, this date giving both sides time for preparation, or any other date that may be convenient for your honor.

We respectfully request that your honor will indicate to us the time and place for the hearing.

A copy of this notice is this day mailed to Geo. H. Christy, Esq., attorney for Westinghouse Air Brake Co. and Geo. Westinghouse Jr., at Pittsburg, Pa.

Respectfully,

BOYDEN BRAKE CO.
G. H. BOYDEN, *Pres't.*

Baltimore, Md., November 26th, 1895.

BOYDEN POWER-BRAKE COMPANY <i>et al.</i> ,	}	
Appellees.		

The motion made by The Westinghouse Air Brake Company and George Westinghouse, Jr., appellees in said cause No. 131, and appellants in cause No. 134, to stay the mandates therein for such time as will enable counsel to prepare and present to the Supreme Court a petition for a writ of *certiorari*, with reasonable allowance of time for the action of said court thereon, was this day heard, counsel for said parties, respectively appellants and appellees, being present, on consideration whereof, it is ordered that said stay be refused, and the clerk is directed to send down the mandates aforesaid as heretofore provided for.

NATHAN GOFF,
Circuit Judge.

Dec. 5th, 1895.

1428

Mandate.

Issued — filed Dec. 9, 1895.

UNITED STATES OF AMERICA, ss :

Seal of the Court. The President of United States of America to the honorable judges of the circuit court of the United States for the district of Maryland, Greeting :

Whereas, lately in the circuit court of the United States for the district of Maryland, before you, or some of you, in a cause between George Westinghouse, Jr. and Westinghouse Air Brake Co., complainants, Boyden Power Brake Company, *et al.*, defendants, wherein the decree of the said circuit court entered in the said cause on the 25th day of April, 1895, is in the following words, to wit :

And now, to wit, this 25th day of April, 1895, the above-entitled cause having come on regularly for hearing, before the Honorable

Thomas J. Morris, district judge, holding circuit court, on bill, answer, replication and proofs taken by and on behalf of the respective parties hereto, and having been argued by Mr. George H. Christy and Mr. Frederic H. Betts for complainants, and by Mr. Lysander Hill, Mr. Skipwith Wilmer and Mr. Hector T. Fenton for defendants, and the court having considered the same, and being duly advised in the premises, it is thereupon ordered, adjudged and decreed:

1st. That the letters patent recited in complainants' bill of complaint, to wit, letters patent of the United States, No. 360,070, dated March 29, 1887, and granted to George Westinghouse, Jr., for a new and useful improvement in fluid-pressure automatic brake mechanism, are a good and valid patent in all respects as regards and to the extent of the subject-matter of invention referred to and summed up in the several claims declared upon herein, to wit: claims numbered one, two and four of said recited patent; that George Westinghouse, Jr., was the true, original and first inventor thereof; and that the complainants have a good and sufficient title thereto, and are entitled to the exclusive right therein and thereunder.

2nd. That the defendants above named by the manufacture, use and sale of fluid-pressure automatic brake mechanism, as set forth and shown in and by the proofs herein, and (for greater certainty herein) more particularly as shown and described in certain

1429 letters patent of the United States, No. 481,134 and No. 481,135, both dated August 16, 1892, and both granted to The Boyden Brake Company, assignee of George A. Boyden, defendants herein, having infringed the said second claim of said recited patent No. 360,070, and have violated the exclusive right of the complainants therein and thereunder, and that a writ of injunction, conformable to the prayer of said bill, and in the usual form, be issued by the clerk, perpetually enjoining and restraining the said defendants, and each of them from any further manufacture, use or sale of the apparatus, mechanism and devices complained of herein and of any other apparatus, mechanism or devices substantially such in construction and operation as that which is referred to in and constitutes the subject-matter of said second claim, and from doing any act or thing in infringement of said second claim, or violation of the exclusive right so as aforesaid vested in said complainants therein and thereunder.

3rd. That reference be made herein to G. Morris Bond, Esq., as master, to take, state and make return of an account of the gains and profits made by said defendants, as also of the damages suffered by said complainants by or on account of said infringement, and that the parties appear before the master and produce books and papers and render accounts as he may, from time to time, direct.

4th. That as regards claims one and four of said patent No. 360,070, the court being of the opinion that defendants' device hereinbefore referred to does not infringe the same, injunction is refused and the bill of complainant is, in reference to such claims, hereby dismissed.

5th. And it is further ordered that all questions of the allowance

Costs are reserved until the final decree; as by the inspection of transcript of the record of the said circuit court, which was brought into the United States circuit court of appeals, for the fourth circuit by virtue of the appeal of the Boyden Power Brake Company, et al., and the cross-appeal of George Westinghouse, Jr., and the Westinghouse Air Brake Company agreeably to act of Congress in the case made and provided, fully and at large appears. And whereas, in the term of May, in the year of our Lord, one thousand eight hundred and ninety-five, the said cause came on to be heard before the said United States circuit court of appeals for the fourth circuit, on the said transcript of record, and was argued and counsel:

On consideration whereof, it is now here ordered, adjudged and decreed by this court, that the decree of the said circuit court, in this cause, be and the same is hereby affirmed with respect to claims one and four of the complainants' patent number 100,070, and reversed with respect to claim two of the said patent. And this cause is remanded to the circuit court of the United States for the district of Maryland with direction to enter a decree therein in conformity with the opinion and decree of this court. Costs in this court to be paid by the Westinghouse Air Brake Company. It is further ordered that the mandate of this court issue after the expiration of twenty days from the date hereof.

CHARLES H. SIMONTON,
Circuit Judge.

November 11th, 1895.

You, therefore, are hereby commanded that such further proceedings be had in said cause, in conformity with the opinion and decree of this court as according to right and justice, and the laws of the United States, ought to be had, the said appeal and cross-appeal notwithstanding.

Witness the Honorable Melville W. Fuller, Chief Justice of our Supreme Court, the ninth day of December, in the year of our — one thousand eight hundred and ninety-five.

February 17, 1896, writ of certiorari of the Supreme Court of the United States, dated January 30, 1896, was produced removing the aforesaid causes into the said Supreme Court.

1431 & 1431½ UNITED STATES OF AMERICA :

I, Henry T. Meloney, clerk of the United States circuit court of appeals for the fourth circuit, do certify that the foregoing is a true transcript of the entire record and proceedings of the said circuit court of appeals in the therein-entitled causes as the same remains upon the files and records of the said circuit court of appeals.

In testimony whereof I hereto set my hand and affix the seal of the said United States circuit court of appeals for the fourth circuit, at Richmond, this 19th day of February, A. D. 1896.

HENRY T. MELONEY,
*Clerk United States Circuit Court of Appeals
for the Fourth Circuit.*

1432 UNITED STATES OF AMERICA, 88 :

The President of the United States of America to the honorable the judges of the United States circuit court of appeals for the fourth circuit, Greeting :

[Seal Supreme Court of the United States.]

Being informed that there is now pending before you a suit in which Boyden Power Brake Company *et al.* are appellants and George Westinghouse, Jr., and The Westinghouse Air Brake Company are appellees and George Westinghouse, Jr., and The Westinghouse Air Brake Company are appellants and Boyden Power Brake Company *et al.* are appellees, which suit was removed into the said circuit court of appeals by virtue of an appeal and cross-appeal from the circuit court of the United States for the district of Maryland, and we, being willing for certain reasons that the said cause and the record and proceedings therein should be certified by the said circuit court of appeals and removed into the Supreme

1433 Court of the United States, do hereby command you that you send without delay to the said Supreme Court as aforesaid the record and proceedings in said cause, so that the said Supreme Court may act thereon as of right and according to law ought to be done.

Witness the Honorable Melville W. Fuller, Chief Justice of the United States, the 30th day of January, in the year of our Lord one thousand eight hundred and ninety-six.

JAMES H. MCKENNEY,
Clerk of the Supreme Court of the United States.

1434 [Endorsed:] Supreme Court of the United States. No. 847. October term, 1895. Boyden Power Brake Company *et al.* vs. George Westinghouse, Jr., *et al.* Writ of certiorari. The execution of the within writ appears from the certified transcript of the record in the causes therein mentioned, which said transcript is

hereto annexed. Henry T. Meloney, clerk U. S. circuit court of appeals, 4th circuit. February 19, 1896.

JAMES H. MCKENNEY,
CLERK

United States Supreme Court.

In the Matter of the Petition

OF

GEORGE WESTINGHOUSE, Jr., and THE WESTINGHOUSE
AIR BRAKE COMPANY for a Writ of Certiorari, etc.

PETITION.

GEORGE H. CHRISTY,

Solicitor for Petitioners,

FREDERIC H. BETTS,

J. SNOWDEN BELL,

BERNARD CARTER & SONS,

Of Counsel.

TO THE SUPREME COURT OF THE UNITED STATES OF AMERICA :

The petition of George Westinghouse, Jr., and The Westinghouse Air Brake Company, for a writ of *certiorari*, directed to the United States Circuit Court of Appeals for the Fourth Judicial Circuit, under the provisions of Section 6 of the Act of Congress, approved March 3d, 1891, and ordering that the Records in a certain appeal and cross-appeal be certified to this Honorable Court for its review and determination.

Said appeal is entitled as follows :

Boyden Power Brake Company, George A. Boyden, President; Charles B. Mann, Secretary; William Whitridge, Treasurer; and Boyden Brake Company, Defendants and Appellants, versus George Westinghouse, Jr., and The Westinghouse Air Brake Company, Complainants and Appellees, No. 131, in said Circuit Court of Appeals.

And the said cross-appeal is entitled as follows :

George Westinghouse, Jr., and The Westinghouse Air Brake Company, Complainants and Appellants, versus Boyden Power Brake Company, George A. Boyden, President; Charles B. Mann, Secretary; William Whitridge, Treasurer; and Boyden Brake Company, Defendants and Appellees, No. 134, in said Circuit Court of Appeals.

Statement of Case.

And your said petitioners thereupon respectfully show to this Honorable Court, as follows :

FIRST. Your petitioners are, and at the time hereinafter mentioned were, citizens of the State of Pennsylvania—the said The Westinghouse Air Brake Company being a corporation duly organized under the laws of said State.

SECOND. Your petitioners, complainants therein, brought suit by bill in equity in the U. S. Circuit Court for the District of Maryland,

for infringement of certain Letters Patent of the United States, against the Boyden Power Brake Company, George A. Boyden, President, Charles B. Mann, Secretary and William Whitridge, Treasurer, defendants therein. By subsequent proceedings, Boyden Brake Company became also a party defendant. All the said parties defendant were citizens of the State of Maryland, and the said Boyden Power Brake Company and Boyden Brake Company were, and so far as is known, still are, corporations organized under the laws of the said State of Maryland.

THIRD. The patent for infringement of which the said suit was brought and prosecuted is Letters Patent of the United States No. 360,070, granted to George Westinghouse, Jr., one of your petitioners, March 29th, 1887, for an Improvement in Fluid-Pressure Automatic Brake Mechanism, the title whereof was, at the time of bringing said suit, duly vested in your petitioners, complainants therein. And infringement was charged of claims 1, 2 and 4 of said patent.

FOURTH. In due time, the said cause came on for hearing on bill, answer, replication and proofs, and was argued before the Honorable THOMAS J. MORRIS, holding Circuit Court. An opinion therein was subsequently rendered by His Honor Judge MORRIS, and a decree was entered in conformity therewith—holding, *inter alia*, that the said Letters Patent No. 360,070 was a good and valid patent; that complainants had a good title thereto; that the defendants therein had not infringed claims 1 and 4 of said patent, but had infringed claim 2 of said patent. As to claims 1 and 4, the bill was dismissed, but as to claim 2 an injunction was allowed, with reference to a Master for an account.

The opinion of the Court therein is reported in 66 Fed Rep., 997, and a copy is annexed as an exhibit hereunto.

FIFTH. Thereupon each party appealed to the Circuit Court of Appeals for the Fourth Circuit.

The defendants therein, Boyden Power Brake Company *et al.* appealed under Section 7 of the Circuit Court of Appeals Act of March 3d, 1891, from so much of the said decree as granted or allowed an injunction under claim 2 of said Patent No. 360,070. Said appeal is the case first above recited, and was docketed in said Court of Appeals as No. 131.

The complainants therein, your petitioners herein, appealed from so much of said decree as *refused* an injunction under claims 1 and 4 of said Patent No. 360,070—and this, under the amendment to said act, approved February 18th, 1895, providing for such appeals—this last appeal being the cross-appeal above recited, and docketed in said Court of Appeals as No. 134.

SIXTH. The said appeals came on for hearing in the said Court of Appeals, before the Honorable Circuit Judges GOFF and SIMONSON and District Judge HUGHES, and were argued in said Court as one case.

Subsequently, and on or about the eleventh day of November, 1895, the opinion of the Court was rendered therein by his Honor Judge HUGHES, *inter alia*, affirming the decree of the Circuit Court under claims 1 and 4 of said patent, and reversing the decree of the said Court under claim 2 of said patent.

SEVENTH The said recited Patent No. 360,070 is confessedly the “ground floor” or “pioneer” patent for the modern “quick-action” railway train brake, as will appear by adjudications of the Courts therein.

An improvement thereon, also held by the Courts to be of high rank in the art, was shortly afterwards patented to George Westinghouse, Jr., one of your petitioners, by Letters Patent No. 376,837, dated January 24th, 1888, the title to which latter patent also became vested in your petitioners.

EIGHTH. In a suit brought by your petitioners against the New York Air Brake Company *et al.*, in the Second Circuit, for infringement, *inter alia*, of the Patent last above named, to wit, No. 376,837, the Court found it necessary to construe not only the said Patent No. 376,837, for infringement of which the suit was brought, but also the said earlier and pioneer Patent No. 360,070. This was done by His Honor Judge TOWNSEND, sitting as Circuit Judge at the final hearing of said cause, the same being known in the reports as No. 4977. Judge TOWNSEND's opinion is reported in 59 Fed. Rep. 581.

NINTH. Said cause No. 4977 having been taken by appeal to the U. S. Circuit Court of Appeals for the Second Circuit, was heard by the Honorable Circuit Judges WALLACE, LACOMBE and SHIPMAN, and

the unanimous opinion of the Court therein was rendered on or about October 15th, 1894, by His Honor Judge SHIPMAN.

In that Court, as in the Court below, it was found that the patent in suit, No. 376,837, was so intimately connected with the previous pioneer Patent No. 360,070 that to construe the former, it was necessary to first construe the latter.

The opinion of the Circuit Court of Appeals for the Second Circuit involving, *inter alia*, the proper construction of both these patents, is reported in 26 U. S. App. ; 11 C. C. A., 528; 63 Fed. Rep., 962. A copy thereof is hereunto annexed.

TENTH. Your petitioner The Westinghouse Air Brake Company, having in the meantime acquired the entire title to both said patents, brought another suit for a new infringement against the said The New York Air Brake Company *et al.* in the said Second Circuit. This new suit was based *inter alia*, as well on said Patent No. 360,070 as on said Patent 376,837. Motion was made for a preliminary injunction therein, which came on for hearing before his Honor Circuit Judge LACOMBE. After argument and consideration, the injunction was granted, as prayed for, under claims 1, 2 and 4 of said first or earlier Patent No. 360,070, as well as under claim 1 of said further Patent No. 376,837.

The opinion of his Honor Judge LACOMBE is reported in 65 Fed. Rep., 99, and being affirmed "*Per Curiam*" on appeal, as to Patent No. 360,070, a copy of Judge LACOMBE's opinion is hereunto annexed.

ELEVENTH. The defendants therein appealed to the Circuit Court of Appeals for the Second Circuit, and the appeal came on regularly for hearing before the Honorable Circuit Judges WALLACE and SHIPMAN and District Judge TOWNSEND. On or about May 28th, 1895, a "*Per Curiam*" decision was filed, *inter alia*, affirming the decision of Judge LACOMBE as to "the first, second and fourth claims of Patent No. 360,070." This decision is reported in 69 Fed. Rep., 715, and a copy thereof is hereunto annexed.

TWELFTH. That, as appears by the foregoing decisions and opinions, the Circuit Court of Appeals in the Second Circuit has adjudicated and declared, in one suit brought by your petitioners, that the second claim of your petitioner's Patent No. 360,070 is a valid claim, covering and protecting a legitimate and valuable sub-

ject matter, and the Circuit Court of Appeals for the Fourth Circuit, in another suit brought by your petitioners, has adjudged and declared that said second claim is invalid, and does not cover subject matter which can be lawfully claimed.

THIRTEENTH. That the subject matter of said second claim is of great value and importance to your petitioners, and is already involved in other suits and proceedings brought and pending in other causes unheard and undecided—and more particularly in a certain suit now pending in the U. S. Circuit Court for the Eastern District of Missouri, brought against the Lansburg Brake Company, *inter alia*, for the infringement of said claim 2 of said Patent No. 360,070.

FOURTEENTH. Your petitioners further show that said decisions or adjudications, in the Circuit Courts of Appeals for the Second and for the Fourth Judicial Circuit, are at variance or in conflict with each other, and that the errors of one or the other of them can only be authoritatively corrected in this Honorable Court.

Also that other of the matters of law so as aforesaid decided by the Circuit Court of Appeals for the Fourth Circuit are at variance with sundry of the decisions of this Honorable Court, as well as of other Circuit Courts of Appeal in other Circuits, and that any errors made therein can only be authoritatively corrected in this Honorable Court.

Your petitioners further allege that (as they are advised by their counsel and verily believe), as to all the matters so at variance, as well as to sundry and divers other matters, the said decision of the Circuit Court of Appeals of the Fourth Circuit contains manifest error of law, as well as of fact, material to the issues of the said cause.

FIFTEENTH. Your petitioners further represent that the matters as to which the Circuit Court of Appeals have adjudicated adversely to your petitioners, and more particularly the matters as to which said decision is in conflict with decisions made by other Circuit Courts of Appeal, and by this Court, are matters in which, if they are not corrected, the rights of your petitioners, as also the interests of the public, will suffer irreparable injury.

Your petitioners further represent that the irreparable injury to which they will be subjected by reason of an adverse, and, as your petitioners believe, erroneous decision by the Circuit Court of Appeals for the Fourth Circuit, is particularly apparent because the invention of the patent in suit, No. 360,070, is one which is used on upwards of 400,000 freight cars at the present time, and said freight cars are operated on all the railroads of the country, and may be found on every railroad from Maine to Florida, and from Boston to San Francisco. Such cars traverse every judicial district in the United States, and infringements upon the said Patent No. 360,070 are likely to occur, and have, in fact, occurred, as your petitioners believe, in every judicial district of the Circuit Courts of the United States, and it will be an irreparable and intolerable source of injury to your petitioners if their Patent No. 360,070, which, as they verily believe, covers and protects them in the exclusive enjoyment of an invention of the character described therein, which is universally used throughout the whole of the United States and in all judicial circuits thereof, should be rendered practically, or, at all events, to a very large extent, useless and inefficient for their protection; because whilst its validity has been sustained by the Circuit Court of Appeals for one Circuit, its validity has been denied by the Circuit Court of Appeals for another circuit.

Such a condition of conflicting decisions it is the proper province of this Honorable Court, as your petitioners are advised, to correct and obviate.

Assignments of Variance and Error.

FIRST. As to the validity of claim 2 of the patent in suit, No. 360,070, as matter of law on the face of such claim, the decision of the Court of Appeals for the Fourth Circuit is in terms, and apparently in scope and effect, irreconcilably at variance with the holding of the U. S. Circuit Court of Appeals for the Second Circuit.

And herein, your petitioners submit the following extract from the opinion of the Court of Appeals for the Fourth Circuit, in the cases Nos. 131 and 134, now sought to be brought before your Honorable Court by writ of *certiorari*:

" We think that when claim 2 of 360,070, in its language describing the action of that device, failed to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston ' by a further traverse, admits air directly

"from the main air pipe to the brake cylinder," it was fatally "defective, claiming only a result which is public property and not identifying the specific means (his own property) by which the result is achieved" (Opinion, p. 19).

In the Court of Appeals in the Second Circuit, this claim 2 of Patent 360,070 was held to be valid.

SECOND. As matter of error herein, your petitioners submit that the said decision of the said Circuit Court of Appeals for the Fourth Circuit, that said claim 2 of Patent No. 360,070 is "fatally defective" in matter of form, or in the substance thereof, is not well founded in fact or in law.

THIRD. As further matter of error herein, your petitioners respectfully submit that manifest error was made by the said Circuit Court of Appeals for the Fourth Circuit, in its rulings as to the effect of the proceedings in and action of the U. S. Patent Office, and herein (Opinion, p. 17).

(1) That error was made in holding as matter of law or fact, without proof, that the said Patent Office "employs the best experts in mechanics which it can secure in this and other countries."

(2) That error of fact was made in holding that the examinations made in the U. S. Patent Office, though "*ex parte* in form," are "nevertheless conducted under hot and skillful contestation in every case of importance."

(3) That, possibly by these errors of fact, error of law was made wherein it was held by the said Court that in granting a later patent to Boyden, without notice of any kind, "that action by the office was in effect a ruling that the Boyden device did not infringe Westinghouse Quick-Action Patent No. 360,070."

(4) Further error was made in holding as matter of evidence that "that ruling [of the Patent Office] takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics."

FOURTH. And as matter of error and variance herein, your petitioners respectfully represent that the force and meaning of the phrase "substantially as set forth," as explained and applied by the said Circuit Court of Appeals for the Fourth Circuit, is directly at variance with the decisions of this Court, and is in error as matter of law (Opinion, pp. 15, 16).

FIFTH. As further matter of error herein, and as a matter irreconcilably at variance with the ruling of the Circuit Court of Appeals in the First Circuit, your petitioners further submit that manifest error was made by the said Circuit Court of Appeals for the Fourth Circuit in holding as matter of law that *the mere erasure* from the original specification of a description of a proposed modification operates as a *disclaimer* of such modification.

And your petitioners respectfully represent to your Honorable Court that in the said decision or opinion of the said Circuit Court of Appeals for the Fourth Circuit, there are sundry and divers other errors manifest on the record material to the issues therein, but which cannot be made readily intelligible except by a comparatively full reference to the testimony and exhibits therein, with possibly the aid of an oral argument. And herein your petitioners would submit anew the assignments of error entered in case No. 134 (Cross-Appeal Rec., pp. 3-5), in connection with the cross-appeal, as also the following :

SIXTH. The Court erred in holding that defendant's valve 22 is an integral valve, or that complainant's patent is limited to a non-integral valve.

SEVENTH. The Court erred in passing at all on the question of an integral as distinguished from a non-integral valve—this, under the pleadings and proofs herein, presenting purely a *moot* case or question.

EIGHTH. The Court erred in holding that defendant's apparatus was not an infringement of claims 1, 2 and 4 of complainant's patent, and each of them.

NINTH. The Court erred in holding that Patent No. 217,838 had ever been used, or was capable of any practically beneficial commercial use, either alone or in connection with Patent No. 220,556, all the proofs being the other way.

TENTH. The Court erred in holding that Patent No. 220,556 ever made, or was capable of making, what is known in this case as an emergency stop—all the proofs being the other way.

ELEVENTH. The Court erred in holding that in Patent No.

220,556, the ordinary work of braking was performed by a partial traverse of the triple piston—all the proofs being to the contrary.

TWELFTH. The Court erred in not reversing the decree of the Court below in case No. 131, and in not affirming the decree of the Court below in case No. 134.

Finally, your petitioners aver that the present case is one in which it is proper for this Court to issue a writ of *certiorari* for the following reasons :

1. The first assignment of error relates to and involves a conflict of decisions by courts of last resort on a matter of law in identically the same question ; that is to say :

Is claim 2 of the Westinghouse Patent "*fatally defective*," because it claims "*only a result*," as decided by the Circuit Court of Appeals for the *Fourth* Circuit, November 11th, 1895 ; or is it valid as held by the Circuit Court of Appeals for the *Second* Circuit, on May 28th, 1895 ?

2. Under the second assignment of error, traverse is made of the correctness of the decision in the *Fourth* Circuit, as affected by the form or phraseology of the claim.

3. The rulings made in the *Fourth* Circuit, as to practice and procedure in the Patent Office, are not only productive of irreparable injury to your petitioners, but unless reviewed and corrected, will operate to the irreparable injury of all inventors and patentees, and especially of those who are entitled to be called pioneers in the arts. If the grant of a *later* patent be a ruling by the Patent Office of non-infringement, and if such ruling be allowed to "take rank as "testimony in the case, of experts of the highest experience, skill "and knowledge in mechanics," the rights of the earlier pioneer patentees cannot be otherwise than irreparably injured thereby—and this under the third assignment of error.

4. Under the fourth assignment of error, it is submitted that the Court of Appeals in the *Fourth* Circuit have adopted a meaning or construction for the words "substantially as described," which is directly at variance with that established by the Supreme Court.

Also, that when dealing with a pioneer patent, Judge HUGHES "confines the inventor's rights to his own means," etc., he is directly and again at variance with the repeated rulings of the Supreme Court, both generally, and also specially in that no distinction is thus drawn between those "means" which are material and substantial, in the combination claimed as such, and such other "means" as are *neither* material nor substantial, to the combination claimed, as such.

5. And under the fifth assignment of error, the decisions in the First and Fourth Circuits are irreconcilably at variance.

And this also involves a question of practice which can only be settled by the Supreme Court, and which, being an important one, not only to your petitioners, but to inventors and patentees generally, ought to be so settled.

Other assignments of error, though material and believed to be well founded, can best be made intelligible by the use of the exhibits and by oral argument.

A certified copy of the entire record of the said recited cases in the Circuit Court of Appeals for the Fourth Circuit, is filed herewith as part of this application.

Whereupon your petitioners respectfully pray that this Honorable Court will be pleased to grant a writ of *certiorari*, requiring the first above-entitled cases, Nos. 131 and 134, in the U. S. Circuit Court of Appeals for the Fourth Judicial Circuit, to be certified to this Honorable Court for its review and determination.

GEORGE WESTINGHOUSE, JR.

THE WESTINGHOUSE AIR BRAKE CO.

By GEORGE WESTINGHOUSE, JR., Pres.

FREDERIC H. BETTS,

GEORGE H. CHRISTY,

Of Counsel for Petitioners.

In the Circuit Court of the United States.

FOR THE DISTRICT OF MARYLAND.

GEORGE WESTINGHOUSE, JR., and THE
WESTINGHOUSE AIR BRAKE COMPANY

VS.

THE BOYDEN POWER BRAKE COMPANY.

In Equity.

(Decided March 11, 1895.)

J. Snowden Bell, Bernard Carter, George H. Christy
and *Frederic H. Betts*, for complainants.

Barton & Wilmer, Cowen & Cross, Hector T. Fenton
and *Lysander Hill*, for defendant.

This is a bill in equity, in usual form, charging the defendant with infringing the Westinghouse Patent No. 360,070, dated March 29, 1887, for a fluid-pressure automatic brake mechanism.

The claims alleged to have been infringed by the defendant are claims 1, 2 and 4, which are as follows:

"1. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, a triple-valve and an auxiliary valve device, actuated by the piston of the triple-valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake-cylinder, substantially as set forth.

"2. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth.

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary-reservoir and a brake-cylinder and to the atmosphere, respectively, and an auxiliary valve actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, substantially as set forth."

The only defense now urged by the defendant is non-infringement.

The history of the pioneer invention of George Westinghouse, Jr., in fluid-pressure brakes, by means of which the brakes of a train of railroad cars can be operated by air pressure controlled by the engineer of the train, and the history of the successive steps and inventions by which he has devised mechanisms adapted to apply that power so as to act automatically on each car, and the scope and fundamental importance of his later inventions by which he has accelerated, in an astonishing degree, the quickness with which the brakes can be applied, almost simultaneously, on each car of a long train consisting of as many as fifty freight cars, has been carefully and fully stated by Judge TOWNSEND, who delivered the opinion in the case of *Westinghouse vs. New York Air Brake Co.* (59 Fed. Rep., 581), and by Judge SHIPMAN in the same case on appeal (63 Fed. Rep., 962), and in the opinion of Judge LACOMBE, filed December 27, 1894, in a case between the same parties in the United States Circuit Court for the Southern District of New York.

The patent now in suit, No. 360,070, March 29, 1887, is the first of the Westinghouse patents in which he describes an additional function, engrafted upon his automatic air-brake, which is intended to be used only in cases of unusual emergency, and which is intended to meet the difficulties of applying air-brakes quickly on long trains. The purpose of the device was to increase the quickness of the serial action

of the automatic brake mechanism on each successive car, by making the triple-valve device of each brake mechanism set in operation the valves on the car immediately in its rear, and at the same time to make use of the train-pipe air, vented for this purpose from the train-pipe at each triple-valve, so as to add its power to the power applied from the auxiliary-reservoir of each car.

The result which Westinghouse was seeking in the new device, described in Patent No. 360,070, was first, and principally, to vent the train-pipe at each car, so as to quicken the serial action of the brakes from car to car; and, secondarily, to utilize the vented air and not waste its power.

Westinghouse discovered that he could accomplish this result by so constructing the ordinary triple-valve of his automatic mechanism that, when in an emergency, the engineer, by widely opening his engineer's valve, and thereby causing a sudden and unusual release of pressure in the train-pipe, could cause the piston of the triple-valve to make an unusual and further traverse and thereby actuate a valve, which opened a port by which the train-pipe air was admitted suddenly and directly into the brake-cylinder, without passing through the auxiliary-reservoir.

This sudden release of air from the train-pipe vented that pipe at the first car, and that venting, in like manner, released the pressure in the train-pipe at the valve of the next car, and so on from car to car with almost instantaneous rapidity.

It is shown that this device, as first constructed, was not entirely successful. It applied the brakes with greatly increased serial rapidity, as compared with any former device, and with much greater power, but not so quickly but that the rear cars impinged against the forward ones with destructive shocks.

The reason for this appears to have been that the operation of venting was not carried far enough, because the port opened by the auxiliary valve was not of sufficient size and did not release the full volume of train-pipe air sud-

denly enough to vent it sufficiently. This defect was remedied by an improved mechanism, devised by Westinghouse and described in his Patent No. 376,837, January 24, 1888.

The success of this improved device has demonstrated that the invention, by which the further traverse of the triple-valve piston, beyond the extent of the traverse required for the ordinary application of the brakes, is made to admit a large volume of train-pipe air directly to the brake-cylinder, was one of great importance.

The proofs show that a quick-action automatic brake, which would give the results which this brake has accomplished, was eagerly sought after by inventors and car builders, and all had failed, until Westinghouse discovered that it could be done by this mode of operation.

In the cases above referred to, in which this Patent, No. 360,070, and the improvement on it, No. 376,837, were discussed with reference to the state of the art and the scope of the invention therein disclosed, these were held to be patents of a fundamental pioneer class, describing an invention of primary importance.

In those cases, the defendants, who were charged with infringing, were using a separate and independent valve to open the port to the train-pipe, and the question was whether or not Westinghouse was restricted to the form of independent valve and the precise mode of actuating it set out in his patent. It was held that he was entitled to a liberal construction of his claims, and that, in respect to the emergency valve, the form of his device was not of the essence of his invention.

In the Boyden mechanism, which is alleged in this case to infringe, I have not been able to satisfy myself that Boyden makes use of an auxiliary valve, in the sense in which that term is employed in the specification and in some of the claims of the Patent No. 360,070, now in suit.

It appears from the specification of Patent No. 360,070, that what Westinghouse meant by the auxiliary valve, which

is made one of the elements of the combination in the first and fourth claims, is such a valve as he has described in his specification, and which is independent of and performs none of the functions of the main valve of the ordinary triple-valve device, and I am not satisfied, notwithstanding the very positive testimony of the complainants' experts, that the poppet-valve 22 of the Boyden mechanism is such a valve; for Boyden's poppet-valve 22 does, as I understand its operation, to some extent, perform the functions of a main valve of the triple-valve, as well as the function of Westinghouse's auxiliary quick-action or emergency valve.

It is probably true that, in the Boyden mechanism, the stem valve *i, k, j*, which I take to be the equivalent of the sensitive graduating valve shown in the Westinghouse Patent No. 220,556, October 14, 1879, is so constructed that it may do, and probably in most cases does do, the work of ordinary braking; that is to say, that, by two or three successive applications of pressure through that smaller and more sensitive valve, the brake-cylinder is filled and the main valve 22 becomes non-essential, or, if lifted off its seat, is moved very gently; but valve 22 will, if the engineer uses his brake valve carefully, do the work of a main valve, as is demonstrated, I think, by the experiments in which the sensitive graduating valve *i, k, j*, was plugged up. So I take it that defendant's valve *i, k, j*, must be held to be the sensitive graduating valve usual in triple-valve devices since the Westinghouse Patent No. 220,556; and the defendant's valve 22 must be considered to be the main valve, and that in defendant's mechanism he has been able, by an ingenious arrangement, restricting the admission of auxiliary-reservoir air to the triple-valve chamber, to cause the main valve to do both main-valve work, when needed, and to do quick-action work, when needed.

As, by the explicit terms of claims 1 and 4, Westinghouse has restricted himself, as to those claims, to an auxiliary valve,

independent of the triple-valve, I hold that the defendant does not infringe those claims.

CLAIM 2.

Claim 2 reads as follows :

"2. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, and a triple-valve having a piston, whose preliminary traverse admits air, from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse, admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth."

The first three elements of this claim are the usual mechanism of an automatic air-brake; the remaining element, which was the only novel one at the date of the patent, is a triple-valve having a piston which, by two distinct movements, performs two distinct functions, the first, its preliminary traverse by which it admits air from the auxiliary-reservoir to the brake-cylinder, which is the ordinary effect of the usual movement of the triple-valve piston, and the second, its further traverse, which is a new and distinct use, admitting air directly from the main air-pipe to the brake-cylinder, resulting in venting the main air-pipe and in producing the quick-action.

Now this, as I understand it, was the invention which Westinghouse brought to light. He discovered, and by experiment demonstrated, that, by a further traverse of the triple piston, train-pipe air could be vented from the train-pipe and that it would give two very important results, namely; first, quickening of the action of the brakes from the forward to the rear cars so that the application of the brakes became almost instantaneous on all the cars, and, second, utilizing the vented air for direct action in the brake-cylinder. Now, although quick-action emergency brakes were being sought for, no one before Westinghouse had accomplished this result and the means by which he accomplished it were entirely novel. Indeed, upon

first impression, it is paradoxical and startling to find that, when a sudden, quick and powerful application of brakes is needed, in the face of impending danger, it is to be obtained by a sudden large release of the pressure in the train-pipe, to the extent of fifteen or twenty pounds below that in the auxiliary-reservoir, and that, by using this low-pressure air to operate the brake-cylinder, instead of the air under greater pressure stored in the auxiliary-reservoir, this remarkably effective application of the brakes is obtained. In the domain of quick-action brakes, this device would seem to belong to that class of pioneer inventions, the patents for which are to be construed so as to be co-extensive with the real invention, if the language of the claim will permit it.

It is shown that Westinghouse was the first who used a further traverse of the triple-valve piston to perform the operation required to vent the train-pipe into the brake-cylinder to effect quick-action. The result was new and the means were new. His claim 2 is broad enough in language to cover every device in which that is done by the further traverse admitting air directly from the train-pipe to the brake-cylinder, substantially by the means described in the specification; that is, by the further traverse actuating a valve which so admits the train-pipe air.

The result accomplished by defendant's mechanism is identical with that of Westinghouse, and the means, by which the mechanism is actuated, so alike, that, in its published trade catalogue, defendant claims that cars fitted with its valves can be used on the same trains with the Westinghouse quick-action brake, because the engineer, in applying or releasing the air-pressure, may treat them as identical; the same functional operations of the valves, and the same results, being obtained from the same changes in the engineer's brake valve, so that there is strong *prima facie* reason to suppose that Boyden's way of using the same release of pressure to vent the train-pipe and to actuate the valves, which produces identical results, may be Westinghouse's way.

In mechanisms actuated by air under pressure, the trans-

mission of power is not visible to the senses as plainly as when it is done by cranks and levers, and, being transmitted by an invisible agency in all directions in which the air can escape, the functions of the instrumentalities by which it operates are more important than their forms, and, in judging of an infringement, we are to direct our minds rather to functional equivalents than mechanical equivalents.

The use by Boyden of a central opening through the triple-valve piston, to admit train-pipe air to the triple-valve chamber, was not new, nor the use of a poppet-valve for the main valve of the triple, both of these constructions having been shown in the Westinghouse Patent No. 141,685, August 12, 1873, and in others of his patents. So that there is nothing in the Boyden device not before exhibited in some one of the Westinghouse Patents; except that he has been able to cause one of the valves of the triple (valve 22), at one stage of the application of brakes, to perform ordinary service work, and, at another, to do quick-action work. This Boyden does by an ingenious construction not before used, by which he restricts the passage of auxiliary-reservoir air into the triple-valve chamber, so that, when the further traverse of the piston suddenly unseats the poppet-valve 22, the port opened by it to the brake-cylinder is so large and the supply of auxiliary reservoir air through the restricted passage so feeble, that the train-pipe air raises its check-valve and vents itself into that chamber, and thence through the large port to the brake-cylinder. For the mechanism embodying this ingenious contrivance, by which the poppet-valve 22 is made capable of doing ordinary service work by a careful, intermittent, slow release of pressure by the engineer, and quick-action work by a quick, sudden release, patents were granted to Boyden (No. 481,135, August 16, 1892, and No. 481,136, August 16, 1892); but, if this construction contains the underlying invention of the patent in suit, which was granted March 29, 1887, Boyden cannot make use of his improvement during the life of that patent.

It is true that, in searching for some device which would give quick-action, Westinghouse had, before the date of the patent in suit, conceived the idea that it might be accomplished by venting the train-pipe at intervals along the train. He had tried having two or three vents, at intervals in the length of the train, controlled by electrical apparatus, and also had tried relief-valves placed in the pipe-coupling of each car, which would open to the atmosphere and vent the train-pipe quickly, in case of accident or other sudden release of pressure in the forward part of the train. This was shown in the Westinghouse Patent No. 217,838, July 22, 1879, but neither of these attempts were successfully applied, and they did not solve the problem of quick-action.

The problem was not solved; indeed, the first step in the direction of solving it does not appear to have been taken until the experiments which led to the Westinghouse Patent now in suit. The substance of the method then devised is the use of the sudden further traverse of the triple-valve piston to open a valve in a manner different from the valve opening made by the preliminary traverse for service braking, thereby admitting train-pipe air to the brake-cylinder without its passing through the auxiliary reservoir.

In the Westinghouse apparatus, the further traverse of the triple-valve piston causes it to impinge against an additional, separate valve which admits the train-pipe air. In Boyden's apparatus, used by defendant, the further traverse pulls the poppet-valve 22, which Boyden substituted for the ordinary main valve of the triple, suddenly off its seat, thereby, in the manner before mentioned, causing the train-pipe air to raise the check-valve and flow with volume, through the triple-valve chamber, direct to the brake-cylinder. The device in Boyden's apparatus, by which the difference of pressures in the triple-valve chamber, between auxiliary-reservoir air and the train-pipe air, is produced and used, is ingenious and admirable; but the result obtained is just the same as when, in the

Westinghouse apparatus, the auxiliary valve is unseated, and the means used are, in my judgment, functionally equivalent.

Under the ruling of *Morley Machine Co. vs. Lancaster*, 129 U. S., 263, and of the many cases cited in the opinion delivered in that case, the rights of a pioneer inventor are infringed by one who accomplishes the same result by means which, although never used for that purpose before, are mechanical equivalents for the means used by the inventor, under a liberal construction of his patent. It was said in that case by Mr. Justice BLATCHFORD (p. 273):

"Where an invention is one of a primary character and the mechanical functions performed by the machine are, as a whole, entirely new, all subsequent machines which employ substantially the same means to accomplish the same result are infringements, although the subsequent machine may contain improvements in the separate mechanisms which go to make up the machine."

In *McCormick vs. Talcot*, 20 How., 402, the controversy arose over a device which McCormick had added to his reaper called a divider, intended to separate the standing grain to be left from that which is to be cut. The Court said:

"If he be the original inventor of the device or machine called the divider, he will have the right to treat as infringers all who make dividers operating on the same principle and performing the same functions by analogous means or equivalent combinations, even though the infringing machine be an improvement of the original and patentable as such."

In *Machine Co. vs. Murphy*, 97 U. S., 120-125, it was said:

"Nor is it safe to give much heed to the fact that the corresponding device in two machines, organized to accomplish the same result, is different in shape or form the one from the other, as it is necessary in every such investigation to look at the mode of operation or the way the device works, and at the result, as well as at the means, by which the result is attained."

The language of the Supreme Court in Consolidated Valve Co. vs. Crosby Valve Co., 113 U. S., 157-171, is applicable.

"The prior structures never effected the kind of result attained by Richardson's apparatus because they lacked the thing which gave success. * * * Taught by Richardson, and by the use of his apparatus, it is not difficult for skilled mechanics to take prior structures and so arrange and use them as to produce more or less of the beneficial results first made known by Richardson."

It is true that a patentee can claim nothing beyond the scope of his patent (Keystone Bridge Co. vs. Phoenix Iron Co., 95 U. S., 274), but the scope and meaning of a broad claim in the patent can only be interpreted by an understanding of the real scope of the invention itself.

If the Westinghouse Patent now in suit is for an invention of a primary character, and if the gist of that invention is the use of the further traverse of the triple-valve piston to open a valve which admits air directly from the train-pipe to the brake-cylinder, with the result that the train-pipe is vented and the train-pipe air utilized, then it appears to me that the defendant cannot exculpate itself from the charge of infringement by the fact that, in its device, the train-pipe air is admitted through the triple-valve chamber and not through a by-passage, nor by the fact that in its device the further traverse of the piston opens the main valve in a special manner, which produces the same result, but does not make use of a separate auxiliary valve; provided, Westinghouse has not by the explicit terms of his claim 2 restricted himself to the use of an auxiliary valve.

I do not think Westinghouse has so restricted himself in claim 2, although he does appear to have done so in claims 1 and 4.

There is, without question, some difficulty and embarrassment in the broad construction of claim 2, growing out of the proceedings in the Patent Office, as shown by the

file wrapper and contents ; but, considering what was the real invention, I am not of the opinion that the legal effect of those proceedings is to restrict claim 2 to a device containing a separate auxiliary valve.

From the contents of the file wrapper, it appears that, as the application was prepared, the first claim of Patent No. 360,070 differed from that which now appears in the patent as granted.

The claim 1 first proposed was

"1. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, a triple-valve provided with a device for admitting air directly from the main air-pipe to the brake-cylinder, substantially as set forth."

It was objected by the Patent Office Examiner that this claim and also claim 2 were anticipated by Patent No. 280,285, to G. A. Boyden, June 26, 1883, and the Examiner requested that a working model of the triple-valve should be furnished.

Boyden's Patent of 1883, No. 280,285, was a form of triple-valve mechanism, intended for use with Westinghouse's automatic air-brake, the object of which was to provide for replenishing the auxiliary-reservoir of each car when the pressure therein had been lessened by leakage and while the brakes remained applied. This was done by the engineer causing, not a release, but a slight increase of the pressure in the train-pipe air, which, acting upon a check-valve in the centre of the triple-valve piston, by a peculiar arrangement of the valves, caused train-pipe air to pass together with auxiliary-reservoir air to the brake-cylinder. The object, function and result of whatever was new and patentable in this Boyden device was altogether different from the object, function and result of the Westinghouse device in Patent No. 360,070, and there seems to be no analogy or comparison which can be made between them.

It is true that the "always-open one-way passage" in the Boyden Patent which, when the check-valve was raised,

allowed train-pipe air to reach the brake-cylinder, was, in the language of the cancelled claim 1 of No. 360,070, "a device for admitting air directly from the main air-pipe to the brake-cylinder," and there were other devices, used by Westinghouse himself, which this wording would include; and the claim was, therefore, justly open to the criticism of the Patent Examiner; but there was no similarity in the means by which the two devices were actuated, no similarity in the object to be accomplished, and no similarity in the mechanical principle of operation. It was simply a fact that there did exist in the Boyden device a passage for train-pipe air direct to the brake-cylinder, which the engineer could cause to open by a slight increase of train-pipe pressure; but there was no hint or suggestion of the important discovery how that fact could be utilized to accomplish the entirely new function necessary to create a quick-action brake, when, in an emergency, quick-action was needed; and how, when quick-action was not needed, it should not interfere with ordinary graduation and service stops. This Boyden device was not in the direction of quick-action, but its opposite.

While, therefore, it was proper that Westinghouse's original claim 1 should be corrected, so as to express more definitely his real invention, this was not because the Boyden Patent, in any manner whatever, anticipated that invention, or suggested it in any of its functions.

For the same reason, there was then inserted in the specification of the Westinghouse Patent No. 360,070, this clause:

"I am aware that a construction, in which 'an always-open one-way passage' from the main air-pipe to the brake-cylinder is uncovered by the piston of the triple-valve, simultaneously with the opening of the passage from the auxiliary-reservoir to the brake-cylinder, has been heretofore proposed, and such construction, which involves an operation different from that of my invention, I, therefore, hereby disclaim."

In the Boyden infringing device now used by the defendant, the passage from the main air-pipe to the brake-cylinder is not "uncovered by the piston of the triple-valve, simultaneously with the opening of the passage from the auxiliary-reservoir to the brake-cylinder"; if it was, the defendant's mechanism would be always a quick-action brake and never anything else; but, on the contrary, in the infringing device, the passage is not opened until there has been a sudden further traverse of the piston, which then brings it into operation for the distinct purpose of quick action. The statement of the so-called disclaimer is strictly true, that the construction of the Boyden 1883 Patent "involves an operation different from" the Westinghouse invention, and the so-called disclaimer in reality disclaims nothing which has relation to the Westinghouse quick-action invention.

The disclaimer was substituted in the place of the following, which had been in the specification, and was cancelled :

"Further, while in the specific construction described and shown, the function of admitting air from the main pipe is performed by a valve separate from that which effects the preliminary admission of reservoir-pressure to the cylinder, a modification, in which the same office is performed by a valve integral with the main valve and formed by an extension thereof, would be included in and embody the essential operative features of my invention."

The testimony tends to prove that this clause of the specification was taken out because the Examiner objected that no such form of triple-valve was illustrated in the drawings. For whatever reason it may have been cancelled, it is not a necessary result that the patentee is precluded from claiming that his patent covers other forms of valve, integral with the main valve, if such is his legal right, when his invention, as disclosed in his patent, is found to be a broad one, and if he is not restricted by his claims and if he has done nothing to impair his right to be protected in his whole inven-

tion. The effort should be to preserve, rather than to forfeit, the inventor's rights.

Keystone Manufacturing Co. vs. Adams, 151
U. S., 144.

The object and scope of the invention, and the means employed to effect his object, are thus stated by Westinghouse in the specification of his patent in suit:

"The object of my invention, is to enable the application of brake-shoes to car wheels by fluid pressure to be effected with greater rapidity and effectiveness than heretofore, more particularly in trains of considerable length, as well as to economize compressed air in the operation of braking by utilizing in the brake-cylinders the greater portion of the volume of air which in former practice was directly discharged into the atmosphere. To this end, my invention, generally stated, consists in a novel combination of a brake-pipe, an auxiliary-reservoir, a brake-cylinder and a triple-valve device governing, primarily, communication between the auxiliary-reservoir and the brake-cylinder, and, secondarily, communication directly from the brake-pipe to the brake-cylinder."

This language exactly describes the infringing mechanism of the defendant.

The amendments made to meet the objections of the patent examiner are not to be construed to disclaim the patentee's actual invention, if such construction can be avoided without doing violence to the obvious meaning of the language.

Lake Shore Railway Co. vs. Car Brake Co., 110
U. S., 229-236.

Reese Button Hole Machine Co. vs. Globe Button Hole Co., 61 Fed. Rep., 958.

It has been urged that the invention disclosed by the patent in suit is not of a meritorious character, because, in the form in which it is there embodied, or at least in the first mechanism manufactured by Westinghouse, it failed of success in some essentials, and was immediately improved by Westinghouse, in a manner which was the subject of a subsequent patent, before it was successful in the use for which

it was intended. The defect developed by experimental test, and which Westinghouse in a few months remedied, was that the opening uncovered by the auxiliary valve was not sufficiently large to suddenly release the full volume of train-pipe air. This was not a defect inherent in the device (59 Fed. Rep., 581-591).

There were structural objections to making that opening large; but, when made larger, the device answered the purpose for which it was intended. It was thought, however, better to remedy the difficulty by adding an auxiliary piston, as well as an auxiliary valve, and it was in that line that Westinghouse carried his further improvements, and he has adopted that form, as the best to be manufactured for general use.

This defect in the patent in suit was not radical, and was only one of those defects common in the first forms of many pioneer inventions, which usually have to be improved upon before they attain commercial success.

It is further urged that in a doubtful case the scale should be turned by the fact that, subsequent to the date of the patent in suit, indeed more than two years after the institution of this suit, Patents Nos. 481,135 and 481,136, August 16, 1892, were granted to Boyden for the mechanism now used by the defendant.

Boyden was entitled to patents for whatever was a patentable novelty in the devices by which he was able to make his valve 22 answer for both service and quick-action work, in connection with the restricted passage B, and for any other patentable novelty in the forms of his mechanism. The widely different forms in which he has illustrated his devices in the two above-mentioned patents show that, taking what Westinghouse had discovered and demonstrated to be the underlying principle of a quick-action brake, a skillful and inventive mechanic can devise many forms for applying it.

But, in his specification of Patent No. 481,135, Boyden alleges that his device differs essentially from Westinghouse's Patent No. 360,070, and involves a new mode of

operation. The question whether it does or not, was the very question pending in this suit, and, so far as the Examiner passed upon it, in allowing the specification to stand, he did so upon the *ex parte* application of Boyden and unassisted by testimony as to the state of the art at the date of the Westinghouse Patent, without testimony as to the scope of the Westinghouse quick-action invention and its great importance and merit; and, therefore, without the opportunity of judging whether or not it was a pioneer invention of a fundamental character, entitled to a construction co-extensive with the invention, or was simply a patent for an improvement in a known art, to be restricted to the form of the device shown in the model and illustrations.

The determination of that question is the starting point in the consideration of the controversy and, in my judgment, the fact that Westinghouse was the first discoverer of the vital underlying invention, should turn the scale in his favor.

The complainants are entitled to a decree for an injunction and account, with a reference to a Master in the usual form.

United States Circuit Court of Appeals

FOR THE SECOND CIRCUIT.

THE WESTINGHOUSE AIR BRAKE
COMPANY

vs.

THE NEW YORK AIR BRAKE COMPANY
ET AL.

Nos. 4976 and
5315.

GEORGE WESTINGHOUSE, JR., and THE
WESTINGHOUSE AIR BRAKE COMPANY

vs.

THE NEW YORK AIR BRAKE COMPANY
ET AL.

No. 4977.

SHIPMAN, C. J. :

The various appeals in these three cases are from decrees of the Circuit Court for the Southern District of New York, upon three bills in equity for the alleged infringement of Letters Patent. No. 4977 was founded upon Letters Patent No. 376,837, dated January 24, 1888, and Letters Patent No. 172,064, dated February 11, 1876, each issued to George Westinghouse, Jr. The Circuit Court decreed that the defendants should

be enjoined against their infringement of the first, second and third claims of No. 376,837, and that the bill should be dismissed as to No. 172,064. No. 5315 was founded upon Letters Patent No. 448,827 to George Westinghouse, Jr., dated March 24, 1891. The Circuit Court decreed that the defendants should be enjoined against the infringement of the first and second claims of this patent.

No. 4976 was founded upon Letters Patent No. 393,784, dated December 4, 1888, to Harvey S. Park, and No. 222,803, dated December 23d, 1879, to George Westinghouse, Jr. The Circuit Court dismissed the bill as to No. 393,784, and decreed that an injunction should issue against the infringement by the defendants of the second, third and fourth claims of No. 222,803. The complainants and defendants have respectively appealed from the decrees which were respectively adverse to them.

These patents are for improvements in railroad brakes by fluid pressure, and will be better understood if they are considered in the order of their relation to each other, rather than as they are grouped in the bills in equity, and therefore Nos. 376,837 and 448,827, which was originally applied for in the application which resulted in No. 376,837, naturally take precedence.

It is necessary to give the history of the development by the patentee of the automatic "quick-action" air-brake system, because the construction of the important claims of the two patents now under consideration and of the patent to Park, No. 393,784, depends to a great degree upon a knowledge of this history, which was accurately condensed by Judge TOWNSEND, as follows :

"The first practical air brake is known as the 'plain brake,' and is described in Patent No. 88,929, granted to George Westinghouse, Jr., April 13, 1869.

"It consisted of a pump, operated by steam from the locomotive boiler, which compressed air into a reservoir located under the locomotive cab, which reservoir

communicated by a pipe with a cock or valve in said cab called the 'engineer's valve,' which was so located as to be readily manipulated by the engineer.

"From this valve a pipe extended back under the tender and was connected to a similar pipe under the entire length of the first car by a flexible hose. Each of the succeeding cars had a similar pipe similarly connected. This pipe was called the 'train pipe.' From the train pipe of each car a branch pipe communicated with the forward end of a cylinder called the 'brake cylinder.' This cylinder was provided with a piston, the stem of which was connected with the brake levers on the car. When the engineer wished to apply the brakes, he opened the engineer's valve and the compressed air from the main reservoir flowed back through the train pipe and branch pipes into the brake cylinder on each car, pushing the pistons backward, causing the piston stems to operate the brake levers and force the brake shoes against the wheels.

"When he wished to release the brakes, he so shifted the valve as to shut off the flow of compressed air from the main reservoir, and to open a port or vent leading from the train pipe to the open air. Thereupon the compressed air in the brake cylinders escaped into the open air, the pressure of the pistons was removed and the pistons were forced forward again by means of springs, thus moving the brake shoes away from the wheels.

"The validity of this patent was sustained in *Westinghouse vs. Gardner & Ransom Air Brake Company* (9 O. G., 538).

"The operation of this plain brake was open to certain objections. It was too slow, and was attended by danger of collision in case one part of the train became detached from the other part.

"The brake next to be considered is known as the 'automatic brake,' which appears to have been patented by George Westinghouse, Jr., about 1872 or 1873.

" It embodied the addition of an auxiliary reservoir and a triple-valve device to each car. Each reservoir was of sufficient capacity to operate its brakes once, thus to provide for automatic action in case of accident. The triple-valve device was located at the junction of connections between pipes leading to the train pipe, the brake cylinder and the auxiliary reservoir. In addition to these three ports, there was a fourth port leading to the open air.

" The operation of this brake was radically different from that of the 'plain brake.' In the former, the compressed air was stored in the main reservoir until required for the application of brakes. In the latter, the main and auxiliary reservoirs and train pipe were always charged with compressed air at working pressure, to prevent the application of the brakes. When the engineer wished to apply the automatic brake, he shifted the engineer's valve so as to cut off the flow of compressed air from the main reservoir and open a port from the train pipe to the open air. The effect of this was to reduce the air pressure in the train pipe, and cause a back pressure from each auxiliary reservoir through the triple valve, which shifted it so as to close the port from the branch pipe to the train pipe, and stop the escape of air from the auxiliary reservoir, to close the port leading from the brake cylinder to the open air, and to open the port leading from the auxiliary reservoir, and connect it with the port leading to the brake cylinder. Thereupon the compressed air in the auxiliary reservoir flowed into the brake cylinder and applied the brakes.

" It will thus be seen that, while the former system was operated by pressure from the main reservoir, the latter was operated by withdrawal of pressure. The result was automatic action in case of accidents, whereby air was caused to escape from the train pipe, as by bursting of hose or the train breaking in two. In such cases the release of pressure operated the triple valve, and automatically applied the brakes.

" It is necessary here to consider 'train-brake graduation' or 'service stops,' as distinguished from 'emergency stops.' While for the latter it may be necessary to admit to the brake cylinder the full pressure of compressed air, say seventy or eighty pounds, yet where it is desired merely to slow up without stopping, it may be necessary to admit only, say, ten or twenty pounds, graduating the amount of flow according to the character of service desired. It is important to bear this distinction in mind, because the appliances hereafter to be considered have been so devised as to provide therefor, and that such graduation shall be under the control of the engineer.

" The chief objection to this automatic brake lay in the fact that it was not capable of successful operation on long trains of freight cars. The time consumed by the progressive operation of the brakes between the grip on the first and last car allowed of so much slack motion between them as to cause violent shocks.

" This automatic brake was publicly tested near Burlington, Iowa, in 1886.

" The growing importance of the subject of automatic freight graduation, the inadequacy of existing systems to protect the lives of railroad employees, and the disastrous results therefrom, had become so evident that, in 1885, the Railway Master Car Builders' Association arranged for series of experiments, known as the 'Burlington trials.'

" The Westinghouse Company and several other companies engaged in the manufacture of brake apparatus, competed at these trials.

" None of the competitors succeeded in stopping long trains of freight cars without violent and disastrous shocks.

" In 1887 the trials were renewed. There were five competing parties, including one of the leading experts for the defendants, and the complainant company. The latter then presented an improved apparatus, covered

by Patent No. 360,070, granted to George Westinghouse, Jr., March 29, 1887.

"The report of the committee of the Car Builders' Association shows that they considered 'the field for improvement open as wide as in 1886,' and concluded that air brakes actuated by electricity were the only ones likely to be capable of successful operation on long trains of freight cars. The improved Westinghouse apparatus, while it reduced the length of time between the application of the first and last brakes, produced greater shocks than did the automatic apparatus of the preceding year.

"In this condition of affairs, George Westinghouse, Jr., set himself to work to obviate these difficulties. Upon the conclusion of the 1887 trials, he renewed his investigations and experiments, and, by certain changes and improvements in the old apparatus and the introduction of new elements, he succeeded, in the latter part of the year 1887, in constructing a quick-action automatic brake, capable of being successfully applied to a train of fifty freight cars, and operative under all conditions of practical railway service.

"On October 1st, 1887, he applied for a patent for this apparatus, and, on January 24th, 1888, the patent was granted. Said Patent, No. 376,837, is the first of the patents in suit.

"Before proceeding to consider in detail the claims of this patent, it should be stated that the following were among the requirements for the practical operation of air brakes :

"1. The regulation of the force to be applied to the brake-shoes so as to secure all necessary graduations, from the mere slackening of speed to the service stop, and from the service stop to the emergency stop.

"2. The automatic operation of the brakes in case of accident.

"3. The practically simultaneous operation of the brakes on each car so that, in long trains of freight cars, shocks might be avoided.

"4. The control of all these operations by the engineer.

"5. Certainty of operation under all conditions."

The automatic brake system constructed in general accordance with the invention described in No. 376,837 complies with all these essential conditions. It was unquestionably the first system which practically solved the problem of immediate stoppage of a long freight train in time of danger, in connection with and supplemental to "train brake graduation," and so promptly was its success recognized that 125,000 of this kind of brakes were bought and used by the railroad companies of this country within a period of little more than three years. It is, therefore, important to understand the nature of the improvement which created success.

The promptness with which an automatic air brake system could be made effectual, depended upon the promptness with which air pressure in the train-pipe could be reduced and the equalization of pressure could be changed. Before the series of inventions originated by the Burlington trials, this reduction had been effected in passenger trains of ordinary length by "venting" the train-pipe or opening a port from the train-pipe to the open air, which was initiated by a turn of the engineer's valve on the locomotive. Westinghouse, in his attempt to create efficient and immediate service upon each car of a long train, enlarged the venting system, so that, when the reduction of train-pipe pressure had commenced by the turn of the engineer's valve, the triple valve under each car should also vent the train-pipe of that car. Each car, therefore, contained its own venting mechanism, and, as the mechanism did its work upon its own car, it hastened the work upon the car next in the rear. Westinghouse also sought to save, and did save, power, by compelling the compressed air thus vented to pass into the brake cylinder instead of into the open air. But sudden and large reduction of pressure is only to be used in a case of emergency, and, therefore, means for such re-

duction must be made supplementary to the means for the ordinary service of the brakes, so that ordinary and extraordinary use of the brakes can each be made available as necessity arises.

The method in No. 360,070 was to make the ordinary range of motion of the triple-valve piston, which was produced by a reduction of train-pipe pressure of a few pounds, do the ordinary work of "braking" a train, and to make an extraordinary range of motion throughout the entire length of its capacity for travel, which was produced by a reduction of fifteen or twenty pounds, do the extraordinary work which gave to the brake the name of "quick-action." When the piston of the triple valve moved through the entire length which it could travel, the stem of the piston came in contact with the stem of the emergency valve, opened it, which uncovered a port, and thereby the train pipe pressure was vented into the brake cylinder. The claims of the patent call the first or ordinary range of motion of the piston "a preliminary traverse," which admits air from the auxiliary reservoir to the brake cylinder, and the second range of motion "a further traverse," which enables the piston to admit air directly from the main pipe to the brake cylinder.

This invention, palpably and confessedly, lacked success in the Burlington trials. The reason of its failure and its remedy in No. 376,837 are described by Mr. Massey, a competent expert for the defendants and the patentee of the infringing valve, whose testimony upon this subject is admitted to be correct. He said, upon direct examination, in reply to the question: "What is the practical objection, if any, to the quick-action triple valve of 360,070, and how is that remedied by the apparatus of 376,837? Before answering, state what is meant by the 'Westinghouse Quick-Action Automatic Brake.'"

"Ans. The term 'Westinghouse' Quick-Action Automatic Brake,' as used by Mr. Stone, undoubtedly refers to the quick-action triple valve described in Patent

376,837, and illustrated on sheet 2 of that patent. It is also the quick-action triple valve which is illustrated in the Westinghouse catalogue of 1890.

"In the quick-action triple valve described in 360,070, in addition to the triple valve, the stem of the piston came in contact with an emergency valve, and the extreme motion of the triple-valve piston caused the emergency valve to open a small passage between the train pipe and the brake cylinder, thus causing a local exhaust of the air from the train pipe, and, therefore, reducing the pressure in the train pipe quicker than would be done by the vent through the engineer's valve. The port which was opened by the emergency valve was necessarily restricted in size, as, in order to be effective, the piston of the triple valve must be able to open it within a moderate reduction of train-pipe pressure, and, therefore, with but little force in addition to that consumed by the piston in moving the ordinary triple-valve mechanism. If the emergency valve had been arranged to open a very large port, the time required to exhaust the train pipe through the engineer's valve, sufficiently to allow the piston to open the emergency valve, would be materially increased.

"This defect in the emergency valve of 360,070 would not be serious in trains of moderate length, as under, say, twenty-five cars; but in the 50-car train used at Burlington, in May, 1887, the effect was disastrous. This defect is remedied in 376,837, by using a supplemental piston to open the emergency valve and actuating that piston by fluid pressure from the reservoir through a passage controlled by a valve which is actuated by the triple-valve piston. In this case the triple valve system has only to open a comparatively small port, in addition to its regular function, and fluid pressure in the auxiliary reservoir then causes the supplemental piston to open the emergency valve."

The length of time required, in the use of the single valve of Patent No. 360,070, to open a sufficiently

large port, above referred to, appears to have been in the mind of Westinghouse in providing a separate piston of the patent in suit to open the emergency valve ; for, in the description of this improved invention, it will be remembered, he states that " its object is to facilitate the application of brakes with great rapidity and full or approximately full force, as, from time to time, required, by the provision of means whereby the admission of air from the brake pipe to the brake cylinders may be effected as directly as practicable, and through passages of as large capacity as may be desired."

No. 376,831 abandoned reliance upon the piston of the triple-valve as the means of opening the emergency valve, and used a supplementary piston, contained in a supplementary chamber and actuated by pressure from the auxiliary reservoir. The port, through which, when uncovered, this pressure passes, is, in the mechanism shown in the specification, uncovered by the excess stroke of the triple-valve piston. The description of the mechanism, which is contained in the next paragraph, is in the language of the opinion in the Circuit Court, and, inasmuch as the intricate mechanisms of the various devices which are the subject of discussion in the three cases, now grouped together, were accurately described by Judge TOWNSEND, his language will be used, instead of attempting to formulate independent descriptions of the same series of devices : " This emergency action is secured in the patent in suit by means of a separate supplemental piston and valve in a supplemental valve chamber below the main slide valve of the triple-valve device. This chamber connects the train pipe with the brake cylinder, communication between them being regulated by the supplemental valve, opening outwardly or downwards, and a check valve opening inwardly or upwards. These valves are held upon the seats, under ordinary conditions, by a spring bearing upon their stems. In the bushing which forms the valve face of the main slide valve are four ports governed by said slide

valve. One of these ports leads to the brake cylinder, two lead to the supplemental-valve chamber on the upper or inner side of the supplemental piston, and one leads to an exhaust port.

"When an emergency stop is to be made, the engineer throws his engineer's valve wide open, thereby causing a sudden and material reduction of pressure. The excess of auxiliary reservoir pressure then forces the main piston stem against said other stem, overcoming the tension of its spring, drives the main piston to the extreme limit of its stroke, and thereby uncovers the ports leading from the auxiliary reservoir to the supplemental valve chamber. This pressure drives the supplemental piston outwardly, or downwards, against the stem of the supplemental valve, and forces it from its seat.

"Thereupon the preponderance of train-pipe pressure in the brake pipe opens the check valve, and the air from the train pipe rushes directly from the brake pipe to the brake cylinder.

"The result of this operation is two-fold. It hastens the application of the brakes on the car on which it is operated, and, by venting the train pipe, it hastens a similar reduction of pressure and consequent similar operation in the next succeeding triple-valve device on the next car.

"The release of the brakes is accomplished by the admission of air from the main reservoir."

The three claims which were found to have been infringed are as follows :

"I. In a brake mechanism, the combination of a chamber or casing having direct connections to a brake cylinder and to a brake pipe, respectively, a valve controlling communication between said connections, and a piston or diaphragm which is independent of, and unconnected with, a triple-valve piston, and is actuated by pressure from an auxiliary reservoir in direction to impart opening movement to said valve, substantially as set forth."

" II. The second claim includes 'a check or non-return valve controlling communication between said valve and the brake-pipe passage of the chamber, substantially as set forth.'

" III. In a brake mechanism, the combination, with a triple-valve, of a supplemental chamber or casing having passages leading to a brake cylinder and to a brake pipe, respectively, a supplemental valve, controlling communication between said passages, a supplemental piston operating independently of the triple-valve-piston, and adapted to impart opening movement to said supplemental valve, and a passage establishing communication between said supplemental piston and an auxiliary reservoir, substantially as set forth."

The vital parts of this mechanism are the supplemental chamber, having direct connections to the brake cylinder and the brake pipe, the valve 41, which controls communication between these connections, the emergency piston 63, independent and unconnected with the triple-valve piston, and actuated by pressure from the auxiliary reservoir in a direction to impart opening movement to the valve. To these essential parts, the defendant would add another, the particular means by which, in the specification, the emergency piston is actuated, viz.: the excess stroke of the triple-valve piston which uncovers the port 61, through which the auxiliary-reservoir pressure passes. Upon the scope of the invention, the question of infringement depends. The defendant insists that the only invention "resides in the use of an emergency piston, which is open to the exhaust port on one side and to the brake cylinder on the other side, and which is not subject to operative pressure from the reservoir, except by the extreme stroke of the triple-valve piston." The assignments of error are confined to this question, and the consequent construction of the first three claims, and to the question of infringement.

The defendants' theory mistakes the character and scope of the invention, which was another and successful way to accomplish the work designed to be accomplished by No. 360,070, and to be effected, upon the same general plan of instantaneous brake-pipe venting, by the new means contained in the supplemental chamber which have been named.

In No. 360,070 the stem of the triple-valve piston directly engaged with the stem of the emergency valve, and consequently its action directly depended upon the movement of the piston. The invention in 376,837 radically departed from this method of actuating the emergency devices, by making a new piston, independent of and unconnected with the triple-valve piston. It was to be actuated by auxiliary reservoir pressure, but the particular means by which this pressure was to be permitted to exert itself, whether continuously or only when a port should be opened, do not constitute an essential part of the invention. Means must necessarily be shown in the specification, but the identical means or the special devices were not, in the language of *Morley Machine Co. vs. Lancaster*, 129 U. S., 263, "necessary constituents" of the invention, either in the specification or in the claim. The skill and mechanical ingenuity of constructors of locomotives can, as will be seen hereafter in the examination of other patents and of the infringing devices, arrange different details of mechanical construction, by means of pistons, valves, ports and springs, which, adopting the supplemental chamber system first conceived and embodied by the patentee, and a kindred, but not precisely the same, mechanical method for the movement of the piston, will accomplish the same result. The patentee was a pioneer in that he designed, in No. 376,837, a new way to accomplish a desired result, but upon the same general idea which he had unsuccessfully tried to work out in the earlier patent. His later patent was the bridge, and not a mere step, which carried railroad-car builders

from failure to success. It is not important now to determine the grade of its pioneership, and whether it may be classed in the list of those inventions which are of the highest rank, but it was an invention created to achieve great necessities and overcome great hindrances, and was one of wide breadth. A court would not be justified in adopting "a narrow or astute construction" which should minimize the character of the invention, leave its real scope open to trespassers, and thus "be fatal to the grant." The claims of the patent do not contract the grant to narrower limits than those which the invention as made by the patentee actually covered, and the claims, therefore, are not limited to the precise mechanical means described in the specification, by which the supplementary piston is actuated. They compel it to be disconnected with and to be independent of a triple-valve piston, and to be actuated by pressure from an auxiliary reservoir by some means equivalent to the means which are described in the specification. The rule, which permits and indeed compels courts to give a wide range to the equivalents which a broad or pioneer patent can include, is thus expressed in *Miller vs. Eagle Mfg. Co.*, 151 U. S., 186: "If the invention is broad or primary in its character, the range of equivalents will be correspondingly broad, under the liberal construction which the Courts give to such inventions."

The defendant uses two forms of devices, known respectively in the case as "Defendant's Quick-Action Triple Valve" and "Defendant's Modified Quick-Action Triple Valve." Each has the supplementary chamber with its contents and in each the various elements conform to the general phraseology of the claims, but in neither does the movement of an emergency piston have any relation to the extreme movement of the triple valve piston, and herein is contained what is claimed to be the essential difference between the patented device and the defendant's valve. In the defendant's "Modified Valve" the pressure upon op-

posite sides of the emergency piston, numbered 13, which corresponds in function with emergency piston 63 of the patent, is always counterbalanced when quick action is not desired, whereas emergency piston 63 of the Westinghouse valve is not subjected to auxiliary pressure until its action is required, when port 61 is uncovered.

In the Defendant's Modified Valve, train pipe pressure is reduced when quick action is wanted, the auxiliary reservoir pressure becomes controlling, forces down emergency valve 20, which corresponds in function with the Westinghouse emergency valve 41, and which, when unseated, opens direct communication between the train pipe and the brake cylinder. This difference between the means which are used to actuate the pistons is not of a patentable importance. The operative features of the invention which are described in the three claims are the same, whether auxiliary pressure is permitted to exert itself continuously or intermittently when a port is opened.

The defendant's earlier device uses two pistons, the first, No. 13, is forced down by auxiliary reservoir pressure, but does not act directly upon the emergency valve. When forced down "it opens a port, whereby train pressure is admitted to the upper side of the other piston (No. 17), which, being thereby forced down, imparts opening movement to an emergency valve leading to the brake cylinder."

It is true that piston 13, which is the one actuated by auxiliary reservoir pressure, does not directly and of itself impart opening movement to the emergency valve, but uncovers a port which admits train-pipe pressure to the brake cylinder, and it is true that piston No. 17 is actuated by the train-pipe pressure thus admitted. These two pistons do the work of the one piston of the defendant's modified valve. Auxiliary reservoir pressure moves the piston which, through the intervention of piston 17, imparts opening movement to the emer-

gency valve. Mr. Massey states the difference between the two valves of the defendant to be that, in the "Quick Action Triple-Valve," the initially operating piston 13 actuates the emergency valve indirectly; that is to say, through the intermediation of the piston 17; while, in the other valve, the initially operating piston 13 actuates the emergency valve directly, as in Patent 376,837." This is not a material difference of a patentable character when considered with reference to this patent, and the result is that each of the defendant's valves is an infringement. The "quick-action valve" infringes the first three claims, while the second form, not having the additional check valve of the second claim, infringes the first and third claims.

No. 448,827 will next be considered. The form of automatic air brake apparatus shown in this patent was originally included in the application for No. 376,837, which also included the form which has been already described, in which port 61 was uncovered by the excess stroke of the triple-valve piston. But the applicant was precluded, by a rule of the Patent Office, from adding to his generic claims a specific claim for the form which is now described in No. 448,827, and therefore a subordinate patent was applied for.

The details of the device are described by Judge TOWNSEND, as follows:

"The alleged invention consists of a valve, controlling communication between a supply passage from the train pipe and a delivery passage to the open air or a brake cylinder. This valve is held in position by a spring, so as to close ports leading to the delivery passage, and not to be moved from its seat by ordinary reductions of pressure for service stops. There is also a diaphragm and valve stem, interposed between the supply passage and a passage to a special reservoir or an auxiliary reservoir. Said controlling valve is connected to said valve stem. Train-pipe pressure passes through a small passage in said diaphragm into said

reservoir, thus equalizing pressure on the opposite sides of said diaphragm.

"Upon a sudden reduction of pressure, sufficient for an emergency stop, the excess pressure on one side of said diaphragm moves it and its valve stem and the said controlling valve downwardly, so as to open said ports and allow the compressed air to pass through the delivery passage to the open-air or brake cylinder."

The two claims of the patent which are said to have been infringed by the defendant's two valves, which have been before described, are as follows :

"1. In a fluid-pressure brake apparatus, normally operated by a triple-valve device, the combination with such an apparatus of a valvular appliance having a casing, provided with supply and discharge passages or connections, and a valve, controlling an exhaust port from the supply passage to the discharge passage, for quickly releasing pressure in the supply passage, said valve being actuated to open the exhaust port by a greater than normal reduction of pressure in the supply passage, independently of the action of the triple-valve device, substantially as set forth.

"2. The combination with a triple-valve mechanism of a discharge valve controlling an exhaust port from a supply passage to a discharge passage for quickly releasing the pressure in the supply passage, said valve being actuated to open the exhaust port by fluid pressure in an auxiliary reservoir on reduction of pressure in the supply passage below the normal degree, in whatever position the slide valve of the triple-valve mechanism may be brought by such reduction, substantially as set forth."

Infringement of these claims is admitted, and the only question is in regard to their validity.

The distinctive feature of the alleged invention is that the emergency valve is actuated to open the exhaust port "independently of the action of the triple-valve device."

The theory of the complainants is that, whereas the leading characteristic of novelty in Patent No. 376,837 is the "utilization of auxiliary reservoir pressure operating a supplemental piston in proper direction to impart opening movement to the emergency valve," the invention of No. 448,827 was the means of imparting movement to the valve by "auxiliary pressure, so applied that the action or non-action of the triple-valve piston shall be eliminated as an element of control," and that its distinctive feature was "the removal from the apparatus of all *obstructive* mechanical connection between the triple piston and emergency valve, whereby the latter may be impeded in its movements by the former."

This theory omits an important characteristic of the novelty of No. 376,837, which is the independency and disconnection of the supplemental piston from the triple-valve piston. In the form left in the application for the patent, after the divisional application was made, there was no mechanical connection between the two pistons, but the stroke of the triple-valve piston exercised a control over the movement of the supplemental piston, by uncovering the port which admitted auxiliary reservoir pressure. The form in 448,827 permits, as do the defendants valves, auxiliary reservoir pressure to be present at all times and to act upon the piston, but counterbalanced during ordinary service stops. It was included in the generic claims of No. 376,837, and in view of those claims no invention could consist in the mere fact of the elimination of the action of the triple-valve piston as an element of control. When the patentee obtained the broad claims of No. 376,837, he exhausted his power to obtain additional patents for mere modifications of means by which the piston should be made independent of the triple-valve piston, unless the modification contained a patentable improvement upon the form disclosed in that patent. For any new and useful improvement which contained also

the element of invention, or for a separate invention, a subordinate patent could be obtained.

Were the changes made in 448,827, after the idea of 376,837 had been embodied in its original form, the work of invention? So far as the first two claims are concerned, the changes consisted in a port from the auxiliary reservoir to one side of the emergency piston, which port was always open, and the counter-balance to reservoir pressure by a spring on the opposite side of the piston so that ordinary variations of pressure would not destroy the equilibrium necessary to be maintained until excessive reduction of pressure should take place. In view of the various forms and modifications and improvements of automatic brakes and brake-mechanism, which had been made known before the date of this invention and which are a part of the record in these three cases, there was no patentable invention in this modified form, apart from the invention shown in No. 376,837. It was simply what the patentee first deemed it to be, a form of the invention of that patent and covered by it. The first two claims of No. 448,827 contain no patentable improvement upon the form specifically described in the claims of its predecessor and are void.

We omit any description of the other grounds upon which the invalidity of these claims is placed by the defendant.

No. 393,784. This patent is subordinate to 376,837. The device which it describes has the supplemental chamber with the emergency piston and valve, and the important elements of the Westinghouse Patent, except that the emergency valve is moved by train-pipe pressure, instead of by auxiliary reservoir pressure.

"This result was accomplished by providing a separate emergency piston and valve, ordinarily exposed to train-pipe pressure above said piston, which pressure served to hold the valve on its seat, and was not affected by ordinary reductions of pressure for service stops.

But the considerable reduction of pressure necessary for an emergency stop caused air from the train-pipe to be vented into the space below said piston, equalizing the pressure on both sides and, acting on the under side of said valve, causing it to be unseated and to thus allow the train-pipe pressure to be vented directly into the brake-pipe cylinder."

The claims said to be infringed are as follows :

"1. In a brake mechanism, the combination of a valve controlling the direct passage of pressure from a train-pipe to a brake cylinder, a piston connected to said valve and actuated wholly by train-pipe pressure, and a valve controlling the train-pipe pressure on the piston for opening and closing the communication between a train-pipe and a brake cylinder through the direct action of train-pipe pressure, substantially as specified.

"2. In a brake mechanism, the combination of a train-pipe, a brake cylinder, an interposed chamber communicating with the train-pipe and brake cylinder, a piston in said chamber, a piston stem, a valve on the piston stem controlling the passage from the interposed chamber to the brake cylinder, and a controlling valve and passages for the admission of pressure from the train-pipe to move the piston and open the valve, substantially as and for the purposes specified."

The emergency piston 13 in the defendant's "Modified Valve" is actuated wholly by reservoir pressure, and this valve is, therefore, not claimed to be an infringement. The emergency piston 13 in defendant's "Quick-Action Valve" is forced down by reservoir pressure, but when it is pressed down it causes train-pipe pressure to be admitted, which acts upon and presses down piston 17, whose spindle presses upon and unseats the emergency valve. Inasmuch as the valve is disconnected from piston 17, it is returned to its seat when train-pipe pressure is removed from the upper side of the piston, mainly by the elastic force of a spring.

This patent is a subordinate one and must receive a narrow construction. It is not permissible to give to the terms of a patent of that class so wide a sweep as to include the various devices which may actuate an emergency valve in a supplemental chamber by train pipe pressure, and the range of its monopoly is a limited one. The language of each claim indicates that a connected valve and piston were to be employed, and Park's method of opening and closing the valve required that they should be mechanically connected. A mechanical connection would not be indispensable, unless there was a necessity for it, or unless a mechanical separation created a difference in the means by which the result was accomplished, which, in view of the narrowness of the invention, was a radical difference. The Park piston holds the valve to its seat, in the normal condition of pressure. It is lifted up when the valve is lifted by train-pipe pressure, and, when extraordinary pressure is removed, it restores the valve to its seat. It does not unseat the valve. The defendants' piston does not hold the valve to its seat and does not restore it to its place. When train-pipe pressure comes upon the upper side of the piston and forces it down, it unseats the valve, and, after pressure has been removed, the spring, as it resumes its shape, returns the valve to its seat. The difference in the way in which the two pistons accomplish the general result would not be a substantial one in a primary patent. It is substantial with respect to an invention which merely substitutes train-pipe pressure for the auxiliary reservoir pressure which Westinghouse used. The Circuit Court properly held that neither claim was infringed.

No. 172,064. The invention of this patent was an improvement upon the improvement patented to Mr. Westinghouse by Patent No. 168,359, and was a part of the brake apparatus used before the invention of the quick-action brake. It related to the direct admission

of air from the brake pipe to the brake cylinder. The defense that the defendant uses the original and not the later improvement was satisfactorily sustained. The peculiarity of the patented invention and of the device used by the defendant is shown in Judge TOWNSEND'S description, as follows :

“ Patent No. 168,359 provides for a piston and slide valve, so arranged that air pressure transmitted through the train pipe shall pass on the under side of the piston, and hold it in an upward position, and thence pass through a side port in the piston-valve case, and certain other ports and passages, into the auxiliary reservoir.

“ The effect of this pressure is to hold the slide valve in position above two connected ports, one leading to the brake cylinder, the other to the open air, so that any pressure in the brake cylinder will escape to the open air, and the brakes will be off. When the pressure is reduced, in order to apply the brakes, the back pressure from the auxiliary reservoir depresses said piston so that it passes down and closes the supply ports and shifts the slide valve, so as to open the port leading to the brake cylinder and exposes it to auxiliary reservoir pressure, and so as to close the port leading to the open air.

“ In Patent No. 172,064, the inventor dispensed with said side port in the valve case and substituted therefor a port through the piston itself. The piston was so arranged, in connection with this port, that said port could be opened or closed without moving the slide valve. This was accomplished by having the stem of the piston fitted to the port in the piston, so that it would close the port when moved into it and open it when removed, and by further providing that the slide valve should be made shorter than the distance between the collars on its stem, thus insuring the necessary slack motion for closing the supply port before the slide valve begins to move.

" Claim 3 is as follows :

" 3. The slide valve H, made shorter than the distance between its end bearings, in combination with the port *s* and stem *c*¹, or relatively arranged with reference to the operation of the valve H while the port *s* is closed, substantially as set forth.

" Defendants' device, as illustrated by 'Defendants' plain triple valve,' contains the slide valve, made shorter than the distance between its end bearings, on the piston stem. It is also provided with two ports, one of which leads from the train pipe, through the piston chamber and by other passages to the auxiliary reservoir. The other port leads from the auxiliary reservoir to the brake cylinder. This port is closed by having the end of the piston stem slide on to it and cover it, like a valve upon its seat.

" There is no port through defendants' piston, and, consequently, no piston stem fitted to enter such port."

The claim is for the valve made shorter than the distance between its bearings with the specified improvements upon 168,359, viz. : the air port through the piston, which is opened and closed by the stem. The effect of this arrangement is stated in the specification, as follows :

" The port *s* will be closed before the valve H begins to move for applying the brakes, and will be kept closed until the valve H shall have been brought back to the proper position for a full release of the brakes. Consequently, the valve H can be operated as may be desired in applying and releasing the brakes and in graduating the brake pressure, without leakage or loss at the air-supply port *s*, and with such port always closed."

It is undoubtedly true that the two devices accomplish the same result and close the supply port before the valve begins to move, but infringement can only be found by giving a construction to the third claim, which disregards the fact that No. 172,064 substitutes the air port *s* with its plug *c* for the side port of 168,359.

The conclusion which the Circuit Court reached was the correct one.

It was stated as follows :

"Inasmuch as complainants claim a combination which contains a port through the centre of a piston, described as substituted for a side port, with which said improvement dispenses, and as defendants' device depends upon the use of a side port, and has no port through the piston, but is made up by a combination of different elements, which are admitted in Patent No. 172,064 to be a part of the prior art, the combination claimed in claim 3 of said patent is not infringed.

"A correct construction of the claim must include the port through the centre of the piston, substituted for the side port of Patent No. 168,359."

The invention of No. 222,803 was an engineer's valve, which, speaking in very general terms, should, by the movements of a single stem or lever, admit and automatically stop admitting fluid pressure to the brake pipes, by means of a charging valve, automatically retain such pressure and permit its escape by an exhaust valve, with means for automatically closing either valve when the desired pressure had been charged into or withdrawn from the train pipe to which the device was connected.

The patentee summarized, in his specification, his invention, as follows :

"It will now be seen that I provide for operating both the supply and the exhaust valves by a single stem, that only one can be opened at once, that either may be opened separately (much or little), and that both may be closed simultaneously and automatically and kept closed whether the brakes are on or off."

This automatic closing of the charging and exhaust valves was a very important part of the invention.

The patented valve, so far as the second, third and fourth claims are concerned, "consists of piston case, containing a piston, governing a charging valve held up

to its seat, partly by fluid pressure and partly by a spring, and an escape valve held down to its seat, partly by gravity and partly by a preponderance of fluid pressure on its upper end.

This governing piston is exposed on its under side to fluid pressure, and on the upper side to pressure from a spring. A screw-stem worked by a crank-arm, is so arranged in connection with said spring that, by the revolution of the crank-arm, the downward pressure of said spring upon said piston is increased or lessened.

The effect of such change of pressure is to cause the piston to be moved upwards or downwards according as it is acted upon by an excess of fluid or of spring pressure, and to open or close the charging and escape valves.

Beneath the lower end of the escape valve, provision is made for a certain amount of slack motion, so that the governing piston may be moved up or down for a short distance without unseating the escape valve. The effect of this arrangement is to prevent the possibility of both valves being open at the same time.

The operation of said apparatus is as follows :

In order to apply the brakes or to open the charging valve, the crank arm is screwed down, and this increase of pressure, transmitted through the stem of the piston-head to the charging valve, unseats it and permits fluid pressure to pass from the boiler or storage reservoir to the train pipe and brake cylinders.

The fluid pressure also passes upward to the space below the piston head and exerts the same pressure upon it as in the train pipe or brake cylinders.

The engineer knows, from his engineer's gauge, just how far to screw down his crank, so that, when the necessary amount of pressure has passed through to the train pipe or brake cylinder, the same pressure will automatically lift the piston and close the charging valve.

The crank arm is screwed up in order to open the escape valve, and, after the proper amount has been

discharged, the escape valve automatically closes in the same way as already shown in the case of the charging valve.

The three claims which the Circuit Court found were infringed are as follows :

"2. As a means for automatically cutting off the fluid-pressure supply when the desired pressure has been charged into the brake cylinders, a piston head P, movable by the operative brake pressure or any excess thereof, in combination with the charging valve and a connection from one to the other, substantially as set forth, whereby such movement of the piston head will result in the automatic closing of the charging valve, substantially as set forth."

"3. The combination of piston head, charging valve, interposed stem and escape valve, substantially as set forth, with reference to the opening and closing of the charging valve, without necessarily opening the escape valve, substantially as set forth."

"4. The combination of piston head, charging valve, interposed stem, escape valve and a single operating stem, adapted by independent connections with both valves to shift both by independent successive motions, substantially as set forth."

The defendants' valve has a single lever which is moved from side to side by a single handle having a reciprocating motion. The valve has also a piston exposed to fluid pressure on both sides, which controls a charging and an escape valve, which perform the same functions as in the patented valve.

"The main lever, which is fastened to said handle, carries an eccentric pin, which passes through said lever, and which moves in the arc of a circle. The right end of the lever is held stationary by a jaw and fulcrum pin; the left end, when said handle is moved to the right, is lifted by the rock-shaft motion imparted by said pin, and strikes against another pin, attached to the escape valve, and raises and opens said escape valve. This lever has

also an upper jaw, which moves in a pin attached to a bell-crank lever, the arm of which is directly beneath the charging valve. In order to open this valve the handle is moved to the left, which causes the main lever and pin to move to the left, and to raise the arm of the bell-crank lever and open the charging valve. Provision is made for slack motion by a space between the top of the escape valve and said pin attached thereto, whereby the left end of the main lever is permitted to have a certain amount of play before it strikes said pin."

In addition to fluid pressure, the piston is "acted upon from below by a bell-crank lever, or bent lever with vertical arms, connected by links to the piston, and to a second lever, which second lever is connected with a light spring."

An attempt was made in the testimony to claim that the patented valve lacked novelty, or that its descent could be traced from Patents No. 129,015, dated July 16, 1872, issued to Fay & Cairns, and No. 141,685, dated August 12, 1873, issued to George Westinghouse, Jr. The Fay & Cairns Patent was for an apparatus for regulating the flow of water in houses and shutting it off when there is an excess of pressure, so as to prevent the bursting of pipes. The Westinghouse Patent was for a triple valve and it was admitted in the course of the testimony that the patent described nothing designed for or capable of performing the functions of the engineer's valve. The Fay & Cairns invention was a pressure regulator, contained no exhaust valve, and could not be an engineer's valve. The idea that either of these patents anticipated or restricted the patentable character of the whole invention is not now entertained. The defendant is, however, of opinion that No. 141,685 is an anticipation of the second claim. The importance of this suggestion will be considered hereafter.

The invention, as a whole, is thus conceded to be without a predecessor, and the importance of an inven-

tion by which both valves could be automatically closed upon the desired amount of pressure being charged into or exhausted from the train pipe is manifest.

The object of the defendants' valve is by the movement of a single handle to accomplish the same results which the patented valve attains, and it is conceded that the valve has a piston head, movable by operative brake pressure or any excess thereof, a charging valve, an escape valve and interposed connections so arranged that the charging valve may be opened and closed without necessarily opening the escape valve, a connection between the piston head and charging valve, consisting of a bell-crank lever, a pin and lever and a projection on the piston head, and that by reason of this connection a movement of the piston head under the operative pressure or any excess thereof, will result in the automatic closing of the charging valve.

But it is contended that the second claim of the patent is void by reason of the Fay & Cairns Patent, that the defendants' valve has not the interposed stem of the third and fourth claims, because the motion of the complainants' piston always acts through the stem to open the valve, that the defendants' piston does not open the charging valve as required in the third claim and does not open either valve, except only that the pin carried by its piston is the fulcrum of the lever when the escape valve is opened, whereas, neither of the valves in 222,803 can be opened except by moving its piston, and therefore that the true construction of the third and fourth claims is as follows:

In regard to the third claim: "The combination of a piston for opening and closing two valves by reverse motions of the piston; those valves; and a part interposed, whereby the motion of the piston in one direction, from its position with both valves closed, opens one of the valves, and its return motion allows that valve to close, while its motion in the opposite direction opens the other valve and its return motion allows that valve to close." In regard to the fourth claim: "The above

combination, with the addition of a single handle by means of which the engineer can vary the pressure on one side of the piston."

The second claim of the Patent contained the case provided with a piston chamber and valve chamber in addition to the three elements which are specifically named.

The Fay & Cairns patent was a water pressure regulator. The specification says that it consisted of a hollow cylinder attached to a valve and communicating at one end with the water pipe into which the water flows through the valve. In the cylinder is a piston whose rod is connected to the valve, a coiled spring is behind the piston under such tension as to hold the valve open until the pressure becomes too great for the pipe beyond the valve, when the water pressure on the piston closes the valve and keeps it closed until the pressure on the piston and in the pipes falls below the power of the spring, when it will open the valve cylinder. There is no exhaust valve, but claim 2 does not include an exhaust valve, and the valve is connected with the piston, whereas, in No. 222,803 the charging valve is closed by a separate spring, but this is thought by the defendants to be immaterial in a structure not having an exhaust valve, "the purpose of separation being to permit a further upward movement of the piston so as to open the exhaust valve after the charging valve has been seated." The needs of a water pressure regulator to be attached to a water pipe which conveys water into a house, and an engineer's valve in which there must be a charging and an escape valve are very different.

In an engineer's valve, opened by a single stem, the charging valve must be separated from the piston or the device would be useless, and it is no answer to the validity of the claim to say that some other fluid-regulating device was operated by a different arrangement of valve and piston which, though it might come within the general terms of that claim, would be useless in the device which was the subject of the patent.

The great dissimilarity in form and appearance between the patented valve and the defendants' valve tends to confuse the mind when the question of the infringement of the third and fourth claims is first looked at. The defendants' valves and piston are not arranged in the same axial line, motion is not communicated to the piston in an endwise direction, but through a series of bell-crank levers, which at first seem to be operating upon a different system from that of the patent. A closer examination shows that the series of operations in the patented valve is substantially reproduced in the defendants' valve by like instrumentalities. It is not denied that the defendants' valve has a series of levers and pins which may be called an interposed stem, and which communicate motion somehow, but it is said that its piston and its stem do not correspond with these elements in the 3d and 4th claims, mainly because in the Westinghouse device the motion of the piston acts through the stem to push the valve open, and the defendants' piston does nothing to open either valve.

It is true that, in the Westinghouse valve, there is a direct connection between the piston and the charging valve, and that the movement of the piston opens the valve, and that, in the defendants' valve, the charging valve is opened by the manual movement of the handle and lever 49, and the piston, at the time, remains stationary.

By the subsequent movement of the piston, when sufficient train-pipe pressure has been admitted, the charging valve is closed automatically.

It is also said that the defendants' piston does not open the escape valve, except that the pin carried by the piston is the fulcrum of the lever when the escape valve is opened. This may also be considered as true, but it should also be said that there is an upward movement of the piston before the valve is opened.

As explained by Mr. Barnes for the complainant, the movement of the handle to the right raises the ful-

crum of the lever, which imposes upward pressure upon the piston ; it moves upward until the elastic resistance below the piston is reduced so much that the train-pipe pressure on top of the piston can lift the escape valve by means of the lever known as 43.

If the third and fourth claims require that one or both valves must be both opened and closed by the motion of the piston, and that the interposed stem must move with the piston to open one or both valves, then there is no infringement. The third claim, for example, is for the combination of piston-head, charging valve, interposed stem and escape valve with reference to the opening and closing of the charging valve. As the invention did not consist in the particular way in which the elements of this combination co-operated, in reference to the mere opening of the valve, and as the language of the claim is not limited to anything more narrow than the actual invention, the construction which the defendant seeks, is not necessary ; the only question is whether the differences which have been stated, and which are, in substance, the difference between the direct action, in the patented device, of the piston, through the interposed stem, in opening the valves and the action of the bell-crank lever, pin and lever, which are the interposed stem of the defendants' device, constitute such a departure from the means which the patentee used and described, as to constitute new and different means which escape a just charge of infringement.

The question of infringement is controlled by the principles restated in *Morley Machine Co. vs. Lancaster*, 129 U. S., 263, and confirmed in subsequent and recent cases (*Miller vs. Eagle Mfg. Co.*, *supra*), and which makes these actual differences, which would be important in a subordinate patent, unessential when a patent for a pioneer invention is under examination. If such differences should be regarded by Courts as essential, when the claims do not make the specific de-

vices essential, patents for pioneer inventions would ordinarily have but little value.

All the decrees of the Circuit Court in case No. 4976, and in case No. 4977, which have been appealed from, are affirmed with costs of this Court. The interlocutory decree of the Circuit Court in case No. 5315 is reversed with costs of this Court, and the cause is remanded to that Court with instructions to dismiss the bill with costs of that Court.

GEORGE H. CHRISTY, FREDERIC H. BETTS, J. SNOWDEN BELL, for the complainants.

J. E. MAYNADIER, FREDK. P. FISH, ESEK COWEN, EDWARD C. JAMES, for the defendants.

UNITED STATES CIRCUIT COURT,

SOUTHERN DISTRICT OF NEW YORK.

THE WESTINGHOUSE AIR BRAKE CO.

VS.

THE NEW YORK AIR BRAKE CO.

LACOMBE, Circuit Judge.

This is an application for a preliminary injunction under three patents, viz: No. 360,070, March 29, 1887, to George Westinghouse, Jr. No. 376,837, January 24, 1888 to the same, and No. 393,784, December 4, 1888 to Harvey S. Park.

It is unnecessary to enter into any elaborate statement of the history of the art, and of the impress left upon it by these inventions. That entire subject has been discussed with great care and set forth at great length in the former opinions of this Court and of the Court of Appeals delivered in the earlier actions between these same parties: 59 Fed. Rep. 581, 63 Fed. Rep. 962. In those opinions it is held that the two patents 360,070 and 376,837 disclosed, the one the emergency valve, the other the supplemental piston or special motor, which, so far as the art has now progressed, appear to be both essential to the structure of a successful quick action air-brake. Both of these inventions achieved great necessities and overcame great hindrances; each is an indispensable part of the "bridge which carried railroad car builders from failure to success"; both were products of the inventive genius of the same man; nothing anticipating either is shown; and the defense of the defendant, in the former action and in this, may truthfully be described in terms of another art:—

by bringing the two patents into juxtaposition, they seek to short-circuit the claims and thus dissipate the invention. This attempt failed in the former suit, wherein No. 376,837, the patent sued upon, was held to be one of wide breadth—one as to which “a court would not be justified in adopting a narrow or astute construction which should minimize the character of the invention, leave its real scope open to trespassers and thus be fatal to the grant”. Wherefore, the Court of Appeals held it to be entitled to a liberal construction with a wide range of equivalents. Although No. 360,070 was not declared upon in the earlier suit, it was discussed at great length and its meritoriousness was clearly recognized. The statements of the problem to be solved, as it stood prior to January, 1888, and of the contribution of 360,070 to that solution, as they are set forth in the opinions above cited, leave no doubt that both the Circuit Court and the Court of Appeals regarded it as a patent of wide breadth, the only difficulty being to find sufficient standing room within the field it occupied to permit of according to 376,837, also, the necessary breadth of construction to cover the infringing devices then before the Court, and thus save to a meritorious inventor the fruits of his novel and most useful invention.

Defendant relies upon the rejection by the Patent Office of the original first claim of 360,070 and the substitution of the present first claim, as an abandonment of the fundamental broad invention therein disclosed. When, however, the reference on which the Patent Office rejected the original first claim (Boyden's Patent, No. 280,285) is consulted, it is apparent that the essential change in the claim is the phrase used to differentiate 360,070, an invention to be used “in the application of the brake”, from Boyden's invention, whose object was to provide for replenishing, “while the brake is on”, the air reservoir or brake cylinder, when the pressure is reduced by leakage &c. There is nothing in the file wrapper or contents to show that the Patent Office required or that the inventor agreed to abandon what was

the great feature of his invention—the emergency valve, or to give up whatever range of equivalents his patent might, as modified, fairly cover.

Both these patents, 360,070 and 376,837, are broad ones, and their claims should be construed to cover the meritorious invention they disclose, unless the language of such claims precludes such a construction. The only question really open on this motion is that of infringement.

Patent No. 360,070.

The first claim of this patent is as follows:

"I. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake cylinder, a triple valve, and an auxiliary valve device, actuated by the piston of the triple valve and independent of the main valve thereof for admitting air in the application of the brake directly from the main air pipe to the brake cylinder substantially as set forth."

Defendant's device has the main air pipe, an auxiliary reservoir, a brake cylinder, a triple valve and an auxiliary valve device, independent of the main valve, for admitting air, in the application of the brake, directly from the main air pipe to the brake cylinder. The means for actuating the auxiliary valve device is stated in the claim to be "the piston of the triple valve". And the way in which it acts, as shown in the patent, is by direct impingement upon the stem of the auxiliary valve device. In defendant's structure the piston of the triple valve acts upon the auxiliary valve device, not directly, but by opening a port, which reduces pressure on one side of another piston in a supplementary chamber, the movement of such supplementary piston opening the emergency valve. None the less is the auxiliary valve device "actuated" by the piston of the triple valve, though two pistons do the work of one, and the action of the triple-valve piston is indirect instead of direct. Such an addition to the mechanical details of the combination is within the doctrine of equivalents, when the original invention is a broad one, as this undoubtedly is, and the language of the

claim fairly covers it, which is the case here—the word “actuated” being applicable equally to indirect and to direct actuation. Nor will it avail defendants, as against the claim of a broad patent, that the addition to the mechanism is itself an advance in the art—an advance, it may be noted, which is not theirs, but one they have appropriated from a subsequent patent of the same inventor. The person who discovered the advantage of a supplemental motor for the emergency valve and devised its mechanism, was, as the Court of Appeals has held, entitled to a broad patent for that highly meritorious invention, which was essential to complete success in the art: but that circumstance did not entitle him to appropriate the meritorious and equally essential emergency valve of the earlier patent, so long at least as he actuated his supplemental motor in the way in which such earlier patent claimed, viz: by the piston of the triple valve.

The second claim of No. 360,070 is as follows:

“2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air pipe to the brake cylinder, substantially as set forth.”

The discussion of the first claim applies equally to this one. In the first claim, actuation by the piston of the triple valve was made an element. In this claim, the inventor more closely limits the mode of such actuation. It is to be by a “further traverse” of that piston. The means shown in the patent is by direct impingement upon the stem of the emergency piston; the defendants avail of the “further traverse” to set in motion supplementary devices which act upon the emergency valve. Both these claims are infringed, as is also the fourth. The fifth, which has not been elaborated upon the argument, contains the additional element of a check valve, and the question of its infringement may be left for final hearing.

Patent No. 376,837.

The first claim of this patent is as follows:

"1. In a brake mechanism, the combination of a chamber or casing having direct connections to a brake cylinder and to a brake pipe respectively, a valve controlling communication between said connections, and a piston or diaphragm which is independent of and unconnected with a triple-valve piston, and is actuated by pressure from an auxiliary reservoir in direction to impart opening movement to said valve, substantially as set forth".

This is the "supplemental chamber system first conceived and embodied by the patentee", an invention which the Court of Appeals has held to be a broad one, and entitled to a wide range of equivalents. When we speak of anything as actuated by air pressure, the phrase necessarily implies movement in one direction or another, as the pressure is increased or diminished. Whether it is set from rest into motion by applying pressure or by withdrawing it, the phrase "actuated by pressure" fairly describes the operation.

The question whether defendant's present device infringes this claim, as did the two devices which were before the Court in the former suit, is a narrow one. The claim of the patent is so fully discussed in the decision of the Court of Appeals, that it will only be necessary to describe defendant's new device.

The supplemental piston Q, when at rest, is pressed upon from below by train-pipe pressure. It remains at rest, because the space between its face and the enclosing walls of the chamber in which it moves is filled with air of like pressure, which reaches such space from the train pipe through two narrow conduits *p* and *u* and a connection *t*. When the device is actuated, upon the excess stroke of the triple-valve piston, the connection *t* is moved, the conduit *p* is, for an instant, closed and then opened to the outer air. Thereupon, the space above the piston is voided of compressed air, and the train-pipe pressure from below, being no longer counterbalanced by pressure in the chamber above, moves

and unseats the valve. It is actuated, therefore, by the withdrawal of the air pressure from the chamber above, which, before it is thrown open to admit of such withdrawal, has been cut off from all connection with the train pipe. Pressure from the auxiliary reservoir at no time operates upon it, either to hold it at rest or to put it in motion. Defendant contends that the claim of the patent must be restricted so as to cover only supplemental devices which are actuated by pressure from the auxiliary reservoir and therefore that its present device does not infringe. The phrases "train-pipe pressure" and "auxiliary reservoir pressure" had, prior to the granting of this patent, acquired a well-known meaning in the art, and the use of one in a claim could hardly be construed to mean the other. But complainant contends that the phrase used in this claim, to describe the means for imparting motion to the supplemental piston, is not "actuated by auxiliary reservoir pressure" nor "actuated by pressures from the auxiliary reservoir", but "actuated by pressure from *an* auxiliary reservoir." If some one should reproduce every detail of the claim, with the single exception of adding a separate and additional chamber or reservoir, which was charged from the auxiliary reservoir and then cut off from it, and should use the force thus stored in that additional or supplementary chamber or reservoir for the sole purpose of imparting motion to the supplemental piston, his device would, within the ordinary use of words, contain the element of actuation "by pressure from *an* auxiliary reservoir", whether the additional chamber were contained, as a sub-reservoir, within the auxiliary reservoir proper, or was placed entirely outside of the latter. The charging of such additional reservoir, not from the auxiliary reservoir but in the same way as the auxiliary reservoir itself is charged, viz: by admitting train pipe pressure into it through a charging port and then cutting off connection with the train pipe, does not seem to involve any substantial difference. And, where the patent is a broad one, as this is, with a full range of equivalents, the

maker of such a device may fairly be held an infringer. Whether the device of the defendant contains such an additional auxiliary reservoir in the chamber P, above the piston face, is the question in dispute. For the brief moment when, after being charged, it is cut off from the train pipe it seems to be such and the compressed air which it contains to be within a broad definition of "auxiliary reservoir pressure", viz: air compressed at the locomotive and which, passing through the train pipe, has got beyond a charging port which thereafter cuts off its connection with the source of supply, and detains it as stored-up pressure to be used in an emergency.

In view of the broad construction given to 376,837 by the Court of Appeals, the defendant's device must be held to infringe this claim. Infringement of the third and fourth claims is not so clear, and those questions must be reserved for final hearing.

Patent No. 393,784.

This is the patent to Park, which the Court of Appeals held to be a subordinate one, entitled to but a narrow construction. Infringement is doubtful, and the question had best be determined upon fuller testimony at final hearing.

Complainant may take an order for preliminary injunction in conformity with this opinion.

December 27, 1894.

[ENDORSED] Circuit Court of the United States for the Southern District of New York.—The Westinghouse Air Brake Co. vs. The New York Air Brake Co.—Opinion.—LACOMBE, C. J.—U. S. Circuit Court, filed, Dec. 27, 1894, John A. Shields, Clerk.

(A copy.)

Clerk.

U. S. Circuit Court of Appeals,
SECOND CIRCUIT.

THE WESTINGHOUSE AIR BRAKE CO.,
Appellee,

vs.

THE NEW YORK AIR BRAKE CO.
ET ALS.,
Appellants.

Per Curiam :

We agree with the Court below that the defendant's apparatus is an infringement of the first, second and fourth claims of Patent No. 360,070, and deem it unnecessary to add anything to the opinion of Judge Lacombe. The question whether the apparatus is an infringement of the first claim of Patent No. 376,837 is too doubtful to be resolved in favor of the complainant upon a motion for a preliminary injunction, and should be reserved for disposition upon the final hearing of the cause. So far as the order appealed from allows an injunction for the infringement of this claim it should be reversed ; otherwise, it is affirmed.

Ordered accordingly.

[ENDORSED.] U. S. Cir. C. of Appeals, Second Cir.
The Westinghouse Air Brake Co., Appellee, vs. The
New York Air Brake Co. et als., Appellants. *Per Curiam.* United States Circuit Court of Appeals, Second
Circuit. Filed May 28, 1895. James C. Reed, Clerk.

Clerk.

[3348]

PREFATORY NOTE.

One or two preliminary matters may require a word of explanation :

FIRST. The composite character of the transcript may be a surprise to the Court.

The Boyden parties, defendants below, in order to get an early hearing in the Court of Appeals, procured an *ex parte* order from Judge GORR, under which the reprinting of the record was dispensed with in the Court of Appeals, and eight composite records were made up by binding together and repaging the records used by the opposite parties on final hearing in the Circuit Court—only a few preliminary and supplementary pages being added.

See "Proceedings in the United States Circuit Court of Appeals, Fourth Circuit," at end of "Transcript," pages 1, 2 and 3.

It is in this way that the "Transcript" now before the Court has acquired its composite form or character.

It consists of :

1st. The title, index, etc., pages I.-VII., followed by an unpagcd leaf.

2d. The Westinghouse (complainants') record, as printed for use in the Circuit Court, pages 1-720.

3d. Documentary exhibits used in the Circuit Court, pages 721-794.

4th. The Boyden (defendants') record as printed for use in the Circuit Court, pages 795-1185.

5th. Documentary exhibits, pages 1186-1338.

6th. Westinghouse (complainants') proofs in reply in Circuit Court, pages 1339-1359.

7th. Opinion of Judge MORRIS in Circuit Court, decree, appeal, etc., pages 1361-1388.

8th. Next follows "Transcript of Cross-Appeal" in terra-cotta covers, pages 1-9.

9th. Lastly, and immediately following, are the "Proceedings in the United States Circuit Court of Appeals, Fourth Circuit" (pp. 1-30).

And herein will be found the opinion of the Court of Appeals, as rendered by Judge HUGHES, commencing with (p. 5) "Statement," and followed by "Opinion" (p. 15).

SECOND. The attention of the Court ought, perhaps, to be called to the fact that the petitioners herein sought to secure a stay of the mandate until the case could be presented to this Court. The motion was refused.

"Proceedings," etc., at end of Transcript, pp. 24-26.

THIRD. If, in view of the sending down of the mandate, the writ of *certiorari* ought to issue to the Circuit Court, instead of to the Circuit Court of Appeals—a matter of practice believed to be solely under control of this Court—then we need only ask further that the Court shape its remedies accordingly.

GEORGE H. CHRISTY,
For Petitioners.

Supreme Court of the United States.

IN RE PETITION

OF

GEORGE WESTINGHOUSE, JR., and
THE WESTINGHOUSE AIR BRAKE
COMPANY for a Writ of *Certiorari*.

BRIEF IN SUPPORT OF PETITION.

The Supreme Court would not now be troubled with a request for its intervention, were it not that the case, in the opinion of counsel, fully justifies, if it does not imperatively require it.

When Congress passed the Act of March 3d, 1891, establishing Circuit Courts of Appeals, and, in patent cases, made their decisions final, it was anticipated that sooner or later conflicting and irreconcilable decisions would or might be rendered. And obviously, as the effect of such conflicts, a patent valid in one Circuit might be invalid in another Circuit; and an act of infringement, if committed in one Circuit, would be enjoined as wrong, and if persisted in, would be punished as a contempt of Court; while in another Circuit the same act would be held to be perfectly lawful, proper and innocent.

It goes without saying that such a state of things, if it should arise, would be, if not intolerable, at least so objectionable that all lawful means should be resorted to, in order to cure or prevent, as the case may be.

And especially is this true, when dealing, as in this case, with patents for railway train appliances. As is well known to everybody, railway cars go everywhere. Probably there is no railway car in the country which is not liable to be used in every one of the nine Circuits into which the United States is for judicial purposes divided. And it will be safe to say that every freight car in the country—and the invention here in controversy relates chiefly to the equipment of freight cars—at some time or other during its life of service, has been, or will be, run or operated in more than one circuit.

Every freight car going from Boston to Chicago, or the reverse, will traverse five Circuits. If it goes on to California, it will then traverse *all* the Circuits, except the fourth and fifth.

If it makes the same journey via the seat of government and St. Louis, it will traverse every Circuit except the fifth. And via New Orleans, it will go through more or less of at least six and possibly seven Circuits.

Hence the very serious evil of conflicting decisions in patent cases which relates to freight cars, cannot be otherwise than obvious.

The present case involves exactly that kind of a case or question.

But it may be admitted that a *mere* conflict is not enough. If for example, the invention in question be *trivial* and of *small importance* either as regards public or private interests, the necessity for review and revision by this Court would be less urgent. Where, however, the contrary appears, and especially where the question is one confessedly involving merit of the *highest* order, and public as well as private interests of *inestimable* value, then it is believed that a case is presented which, when the decisions thereon are at variance with each other, or with the well-settled law of the land, should be brought up for review.

The present case is one of that kind—the patent being a “pioneer” patent of high merit, great utility and of inestimable value in promoting the public interest.

The primary, ground-floor patents by which Mr. Westinghouse sought to cover and protect his invention of the "quick-action" brake, are two in number—known as Nos. 360,070 and 376,837. And, as is always the case with inventions of great merit and great commercial value, both patents were extensively infringed.

The first case to be reached on final hearing was, *inter alia*, for infringement of the second patent, No. 376,837. The two patents were so closely allied that, in order to construe No. 376,837, the Court was compelled first to construe the prior or first patent, No. 360,070. This was done by Judge TOWNSEND in the Circuit Court, and his reasoning and conclusions therein were adopted and affirmed by the Circuit Court of Appeals in the Second Circuit. Both patents were broadly construed in both courts.

Westinghouse vs. New York Air Brake Co., 59 Fed. Rep., 581.

Westinghouse Air Brake Co. vs. New York Air Brake Co., 11 C. C. A., 528; 26 U. S. App., ; 63 Fed. Rep., 962.

With the proper exhibits before the Court, and by a comparison therewith of the plain import of the decision of the Court of Appeals, the fact that *both* patents were construed, could be made to appear; but this is not necessary. In a later suit between the same parties, based on a new infringement, in which both patents were included, and on a motion for a preliminary injunction, Judge LACOMEE, who was a member of the Court of Appeals when the previous case was heard and decided, summed up with great brevity and force the views of that Court as embodied in the two opinions above cited. To quote his exact language (65 F. R., 99, 100), Judge LACOMEE says :

" In those opinions it is held that the two Patents 360,070
 " and 376,837 disclosed, the one the emergency valve, the
 " other the supplemental piston or special motor, which, so
 " far as the art has now progressed, appear to be both essen-
 " tial to the structure of a successful quick-action air brake.
 " Both of these inventions achieved great necessities and over-

"came great hindrances; each is an indispensable part of
 "the 'bridge which carried railroad-car builders from failure
 "to success;' both were products of the inventive genius
 "of the same man; nothing anticipating either is shown."

* * * * *

"Although No. 360,070 was not declared upon in the
 "earlier suit, it was discussed at great length, and its meri-
 "toriousness was clearly recognized. The statements of the
 "problem to be solved as it stood prior to January, 1888, and
 "of the contribution of 360,070 to that solution, as they are
 "set forth in the opinions above cited, leave no doubt that
 "both the Circuit Court and the Court of Appeals regarded
 "it as a patent of wide breadth; the only difficulty being to
 "find sufficient standing room within the field it occupied to
 "permit of according to 376,837 also the necessary breadth
 "of construction to cover the infringing devices then before
 "the Court, and thus save to a meritorious inventor the fruits
 "of his novel and most useful invention."

That such was undoubtedly the force given to the prior Patent 360,070 by the Court of Appeals for the Second Circuit will further appear from the views which, in their first decision, they expressed of the second patent, 376,837. Of it they say (63 Fed. Rep., 962, 969):

"The defendants' theory mistakes the character and scope
 "of the invention, which was another and successful way to
 "accomplish the work designed to be accomplished by No.
 "360,070, and to be effected upon the same general plan of
 "instantaneous brake-pipe venting by the new means con-
 "tained in the supplemental chamber which have been
 "named. In No. 360,070 the stem of the triple-valve piston
 "directly engaged with the stem of the emergency valve
 "and consequently its action directly depended upon the
 "movement of the piston. The invention in 376,837 radically
 "departed from this method of actuating the emergency de-
 "vices by making a new piston independent of and uncon-
 "nected with the triple-valve piston. It was to be actuated
 "by auxiliary reservoir pressure, but the particular means by
 "which this pressure was to be permitted to exert itself,

“ whether continuously or only when a port should be opened,
 “ do not constitute an essential part of the invention. Means
 “ must necessarily be shown in the specifications but
 “ the identical means or the special devices were not, in
 “ the language of *Machine Co. vs. Lancaster*, 129 U. S. 263,
 “ 9 Sup. Ct., 299, ‘necessary constituents’ of the invention,
 “ either in the specification or in the claim. The skill and
 “ mechanical ingenuity of constructors of locomotives can, as
 “ will be seen hereafter, in the examination of other patents
 “ and of the infringing devices, arrange different details of
 “ mechanical construction, by means of pistons, valves, ports
 “ and springs, which, adopting the supplemental chamber
 “ system first conceived and embodied by the patentee, and
 “ a kindred, but not precisely the same, mechanical method
 “ for the movement of the piston, will accomplish the same
 “ result. The patentee was a pioneer, in that he de-
 “ signed, in No. 376,837, a new way to accomplish a de-
 “ sired result, but upon the same general idea which
 “ he had unsuccessfully tried to work out in the earlier
 “ patent. His later patent was the bridge, and not a
 “ mere step, which carried railroad-car builders from failure
 “ to success. It is not important now to determine the grade
 “ of its pioneership, and whether it may be classed in the list
 “ of those inventions which are of the highest rank ; but it
 “ was an invention created to achieve great necessities and
 “ overcome great hindrances, and was one of wide breadth.
 “ A court would not be justified in adopting ‘a narrow or
 “ ‘astute construction’ which should minimize the character
 “ of the invention, leave its real scope open to trespassers,
 “ and thus ‘be fatal to the grant.’ The claims of the patent
 “ do not contract the grant to narrower limits than those
 “ which the invention as made by the patentee actually cov-
 “ ered, and the claims, therefore, are not limited to the pre-
 “ cise mechanical means described in the specification, by
 “ which the supplementary piston is actuated. They compel
 “ it to be disconnected with and to be independent of a
 “ triple-valve piston, and to be actuated by pressure from an
 “ auxiliary reservoir by some means equivalent to the means
 “ which are described in the specification. The rule which
 “ permits, and indeed compels, courts to give a wide range to
 “ the equivalents which a broad or pioneer patent can include

" is thus expressed in *Miller vs. Manufacturing Co.*, 151 U. S., 186 ; 14 Sup. Ct., 310 : ' If the invention is broad or " primary in its character, the range of equivalents will be " correspondingly broad under the liberal construction which " the courts give to such inventions.' "

When the present case was on hearing at Circuit, his Honor Judge MORRIS found the invention of this Patent 360,070 " paradoxical and startling." Thus he says (66 Fed. Rep., 1000, 1001) :

" Now, although quick-action emergency brakes were being sought for, no one before Westinghouse had accomplished this result, and the means by which he accomplished it were entirely novel. Indeed, upon first impression, it is paradoxical and startling to find that, when a sudden, quick and powerful application of brakes is needed in the face of impending danger, it is to be obtained by a sudden large release of the pressure in the train pipe, to the extent of 15 or 20 pounds below that in the auxiliary reservoir, and that by using this low-pressure air to operate the brake cylinder, instead of the air under greater pressure stored in the auxiliary reservoir, this remarkably effective application of the brakes is obtained. In the domain of quick-action brakes this device would seem to belong to that class of pioneer inventions the patents for which are to be construed so as to be coextensive with the real invention, if the language of the claim will permit it."

And the Court of Appeals for the Fourth Circuit make the same admission in the present case (Opinion, p. 19) :

" That this invention of Westinghouse, thus undefined [the Court then referring to claim 2], is one of the highest value to the public, and that it is a pioneer one in the art of quick-action air brakes is not denied, and is conceded. It is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal protection from the Courts in construing the claim."

These adjudications by two Circuit Courts and two Circuit Courts of Appeal, would seem to establish sufficiently our proposition

that the invention which is now brought to the attention of the Court, is one of no ordinary magnitude and importance. None of greater merit and value, except perhaps the Bell telephone and the incandescent electric lamp, has reached this Court during the present generation; and among those inventions which are for securing the safety of life and property, the Reports disclose none which even approach it in its bearing on public interests.

The First Assignment of Variance and Error.

Claim 2 of Patent 360,070 is the claim which, as is believed, in some respects, best expresses, sums up and covers one of the essential mechanical features and combinations of operative mechanism, which constitute the "pioneer" or basic invention here in question.

The Circuit Court of Appeals for the Fourth Circuit, in the opinion rendered by his Honor Judge HUGHES, says that this claim 2 is invalid, or, to use the exact language employed, that it is "fatally defective."

And this is so held by that Court, not because it is old, nor on account of anything shown in the prior art, but because, by reason of the fact that, omitting, as it did, to specify the particular means or mechanism by or through which the second or "further traverse" of the triple valve piston, opened the emergency valve and admitted air from the train pipe to the brake cylinder, it was to be held invalid, or as stated, because it claimed "only a result." In other words, the claim was held invalid as a matter of law arising on the face of the claim.

The ruling of that Court on that question is thus formulated (Opinion, p. 19):

"We think that when claim 2 of 360,070 in its language describing the action of that device, failed to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston, 'by a further

"traverse, admits air directly from the main air pipe to the brake cylinder," it was fatally defective, claiming only a result which is public property, and not identifying the specific means (his own property) by which the result is achieved."

This ruling is directly in conflict with a holding of the Circuit Court of Appeals for the *Second Circuit*.

It was there held that this claim 2 of Patent 360,070 was valid, and the action of the Court below in awarding an injunction under this claim was affirmed. And this injunction is still in force in the Second Circuit.

The case at Circuit in which the injunction was granted has already been quoted from (*Westinghouse vs. New York Air Brake Co.*, 65 Fed. Rep., 99). Infringement was alleged *inter alia* of 360,070 and 376,837. Judge LACOMBE granted a preliminary injunction under claims 1, 2 and 4 of 360,070, and claim 1 of 376,837. And it goes without saying that the allowance of an injunction, necessarily presupposes the validity of the claim under which the injunction was granted.

Defendants appealed, and the appeal was heard by Circuit Judges WALLACE and SHIPMAN and District Judge TOWNSEND. A "*Per Curiam*" opinion was filed (69 Fed. Rep., 715), affirming the decree of the Court below as to claims 1, 2 and 4 of Patent No. 360,070, and reversing only as to claim 1 of the other Patent No. 376,837.

This makes a clear case of conflict of decision between the Circuit Courts of Appeals of the Second and Fourth Circuits in the matter of an invention of highest value and importance—that is, the invention of claim 2—not only to the owners of the patent, but equally, or perhaps more so, to the public at large. And hence, it is believed to be a case calling for the intervention of this Court for purposes of review and revision.

And the urgency of the case becomes the stronger in view of the fact stated in the "thirteenth" paragraph (p. 5) of the petition herein,

that there are other causes involving this claim—unheard and undecided—and more particularly one in the Eastern District of Missouri.

If further proof were needed of the high value and importance of this Westinghouse "Quick Action" invention, the extent and character of the litigation thereunder would fully establish it. With approximate correctness the rule may be mathematically stated that the merit and value of a patented invention are directly as the square of the infringements that have taken place under it. Extensive infringement, widespread and vigorously-contested litigation are sometimes the best proof of meritorious invention.

It would seem to be unnecessary to do more than call the attention of the Court to the serious effects which are likely to follow from such a conflict of decisions. A basic claim for a pioneer invention, usable only on railway trains, valid and to be enforced in one Circuit, and at the same time invalid and *not* to be enforced in another Circuit, would, from a commercial and business standpoint, be regarded as simply intolerable. Public interests, independently of private rights, demand that the law as to the rightful use and control of railway train appliances, shall be uniform in all the Circuits, so that a car, whether free of the patent or subject to the patent in any one Circuit, shall sustain exactly the same relationship to that patent in all other Circuits. And, in the present case, there seems to be no way by which this desirable end can be secured except through exercise by this Court of its statutory right of review and revision.

In order not to overlook anything of importance bearing on this question, note should be made of the possible suggestion that this particular ruling of the Court of Appeals in the Fourth Circuit was, in part, at least, the result of the view which that Court took of the prior Westinghouse Patent, No. 220,556. Judge HUGHES does not so state his conclusions, but if he did, the case would remain the same as before. *The New York Court had this same patent before it, No. 220,556.* The Court of Appeals in the Second Circuit did not apparently consider it of enough importance to require discussion,

but as it is specifically mentioned by its number in Judge TOWNSEND's opinion (59 F. R., 586), it was actually in the case and before the Court, and the adjudication in the Second Circuit must be regarded as having been made in view thereof.

Hence there is nothing in this suggestion which can lessen or wipe out the variance or conflict which exists as between the decisions of these two Courts. They are directly at variance not only as matter of law, but also on the same state of facts.

These considerations are believed to sustain fully our first assignment of variance and error.

Second Assignment of Error.

"SECOND. As matter of error herein, your petitioners submit that the said decision of the said Circuit Court of Appeals for the Fourth Circuit, that the said Claim 2 of Patent No. 360,070 is 'fatally defective' in matter of form, or in the substance thereof, is not well founded in fact or in law."

The said claim 2 as printed in the opinion (p. 15) of that Court, and employing the italics which the Court has adopted to indicate the main feature of novelty and infringement, runs as follows :

" 2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake cylinder, and *which by a further traverse admits air directly from the main air pipe to the brake cylinder, substantially as set forth.*"

Your petitioners aver and submit that—no other part of the claim being objected to—the portion so in italics is not "fatally defective" either in fact or in law.

The "*means*" are clearly defined, and the claim is not "*unlimited.*"

(1) The second word in italics, "*which*," by its reference to its antecedent "*piston*," defines the *first* "*means*."

(2) "*A further traverse*," motion or movement of that piston is the *second* "*means*."

(3) The *third* "*means*," *a suitable valve*, is as necessarily implied as if it were named. The "*further traverse*," which is the second "*means*," "*admits air directly from the main air pipe to the brake cylinder*."

There is only one "*means*" known in the entire range of the mechanic arts by which to admit air from one receptacle to another, and that means is *a valve*.

(4) The *fourth* "*means*" is "*the main air pipe*."

(5) The *fifth* "*means*" is "*the brake cylinder*."

The fact that the claim omits to specify, and is not, in fact, confined to, the specifically illustrated and described connecting mechanism by and through which the "*further traverse*" of the *piston* opens, the *valve* does not make it "*fatally defective*," nor enable an infringer, who varies those means, to escape the claim.

This has been so recently settled by a unanimous opinion of this Court that a single citation is sufficient.

In *Deering vs. Winona Harvester Works*, 155 U. S., 286, 302, this Court said (p. 302) :

"Defendants further insist that the twentieth claim of this patent is invalid by reason of the fact that, if the board *d* be construed, as it evidently must, as a board pivoted to the butt adjuster, the combination is incomplete and inoperative, because the means by which it is held and controlled are not stated in the claim. * * * Admitting that additional elements are necessary to render the device operative, it does not necessarily follow that the omission of these elements invalidates the claim, or that the precise elements described in the patent as rendering it operative

" must be read into the claim. If Steward were, in fact, the " first to invent the pivotal extension to a butt adjuster, he is " entitled to a patent therefor, though the infringer may " make use of other means than those employed by him to " operate it (*Loom Co. vs. Higgins*, 105 U. S., 580, 584).

" In such case any appropriate means for making it " operative will be understood. Otherwise, the infringer " might take the most important part of a new invention, and, " by changing the method of adapting it to the machine to " which it is an improvement, avoid the charge of infringing " ment."

For these specific reasons for assignments of errors of fact, your petitioners respectfully represent and submit that, in so far as relates to any matter of law, or any question of the form of the claim, it is not true that the said claim 2 claims " only a result."

And for the same reasons and to the same extent, your petitioners submit that the decision of the Circuit Court of Appeals in the Fourth Circuit, as to the invalidity of said claim 2 is manifest error, and that the decision of the Circuit Court of Appeals for the Second Circuit, that the said claim 2 is valid, is manifestly correct.

The discussion of this question and the conclusions reached in the opinion rendered by Judge SHIPMAN in the Court of Appeals, Second Circuit, quoted *supra*, are believed to be conclusive in their cogency.

Westinghouse Air Brake Co. vs. New York Air Brake Co., 63 Fed. Rep., 962, 969.

We are unable even to surmise a reply to our position herein, unless possibly it be this : That what Judge HUGHES meant to say, is that *if* claim 2 of 360,070 be so broadly construed as to cover or include the defendant's apparatus, then it must do so by covering or including the function common to the apparatus of both com-

plainants and defendants, and that a patent which covers a function is void.

If this surmise is correct—and we cannot think of any other—a sufficient answer thereto may be briefly stated :

(1) Whatever Judge HUGHES may have meant, *that* is not what he said. He pronounces claim 2 to be “fatally defective,” and he does so without any conditions or limitations of any kind whatsoever. If he means what he says, and if what he says is not subject to correction in this Court, then it necessarily follows that claim 2 is absolutely void and of no force whatever, within the territorial limits of the Fourth Judicial Circuit. Nor can we *now* see how any Circuit Court in the Fourth Circuit could even listen to an argument to the contrary.

(2) The reason assigned by Judge HUGHES in support of his conclusion that said claim 2 is “fatally defective” is inconsistent with any suggestion that he really meant something else or something less. His language is brief, but clear and expressive beyond any apparent doubt or ambiguity. He says (Opinion, p. 19) :

“ It [claim 2 of 360,070] was fatally defective, claiming only a “result which is public property, and not identifying the specific “means (his own property) by which the result is achieved.”

Thus he seems to say as clearly as words can say it :

FIRST. That the claim is “*fatally defective*.”

SECOND. Because “*claiming only a result*.”

THIRD. He says that this result “*is public property*.”

[What Judge HUGHES meant by saying that this result “is public property” is not clear, for in the next sentence he says that “this invention of Westinghouse * * * is a pioneer one,” etc. If so, then the result was *not* “public property.” But if he means that *all results* are “public property,” then this phrase is to be read as the assignment by him of an additional reason for holding the claim to be void.]

Now, neither of these reasons have anything to do with the prior state of the art, nor with the issue of infringement, nor with the

proofs in the case. It is a bald holding that claim 2 is absolutely void for any purpose whatever, at least in the Fourth Circuit.

And we ask that this holding be reviewed, in this Court :

1st. Because it is directly in conflict with the decision of the Circuit Court of Appeals in the Second Circuit, where this claim was held valid, and where a defendant is now under injunction under it.

2d. Because it is erroneous in its reasonings as well as in its conclusion.

3d. Because such a holding must necessarily introduce serious confusion and conflict in the different Circuits in the administration and application of remedies thereunder ; and

4th. Because it will, unless corrected, work irreparable injury to complainants, as to which latter more will be said presently.

Third Assignment of Error.

The present suit was originally brought in the Circuit Court on December 12th, 1889. *A little over two years later*, under date of August 16th, 1892, Mr. Boyden, one of the defendants, and president of defendant company, procured certain patents under the alleged protection of which the defense was thereafter conducted. Of these Boyden Patents, and of their relation to the case, Judge HUGHES says (Opinion, p. 17) :

“ This question [of infringement] was presented necessarily to the Patent Office of the United States when
 “ Boyden applied for a patent for the device under consideration. That Office employs the best experts in mechanics
 “ which it can secure in this and other countries. Its examinations are indeed *ex parte* in form, but they are nevertheless conducted under hot and skilled contestation in
 “ every case of importance ; and its decisions, though not
 “ conclusive, are entitled to great respect. That Office, after
 “ full examination, awarded a patent to Boyden on the 16th
 “ day of August, 1892, for his quick-action improvement on
 “ the device of Patent 220,556, and that action by the Office

“ was, in effect, a ruling that the Boyden device did not infringe Westinghouse's quick-action Patent Number 360,070. That ruling takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics. That ruling was subsequent to the issuing to Westinghouse of both the patents, Numbers 360,070 and 376,837, four years after the latter patent, when the Patent Office had full knowledge of them.”

The above ruling of the Court is excepted to, as well generally as specifically for the following reasons :

(1) It is not true as matter of fact or matter of law, that the Patent Office “ employs the best experts in mechanics which it can secure in this and other countries.”

Under a system of promotion regulated by the rules of our civil service system, ninety-six Examiners are employed at salaries ranging from \$1,400 to \$2,500 per annum.

Whether such low salaries under our civil service system can command the services of “ the best experts,” etc., is too doubtful to constitute properly a part of an adjudication as to valuable rights of property.

(2) The ruling that the examinations made in the Patent Office, though “ *ex parte* in form,” “ are nevertheless,” as stated in the extract above quoted, “ *conducted under hot and skilled contestation in every case of importance,*” is wholly an error. The only contests which can possibly take place in the Patent Office, under any Act of Congress now in force, are in interference cases—and Boyden and Westinghouse were never in interference. All other cases are *ex parte*, the proceedings therein are secret, and as to them no contest can possibly arise.

These errors, though perhaps comparatively small in themselves, lead up to two other errors, both of which are material.

(3) By the grant of a later patent to Boyden it is stated in the extract above quoted, “ that action by the Office was in effect a

"ruling that the Boyden device *did not infringe* Westinghouse's "quick-action patent, number 360,070."

And at that time,—that is, at the time this Patent Office action was taken,—it will be remembered, this case and this question were pending in the Circuit Court.

The question of infringement, under the law, does not belong to the Patent Office, and until the present decision was rendered, it has never been so held.

The ruling or decision thus made, and stated with such freedom from ambiguity, coming as it does from a Court of last resort, is *alarmingly dangerous* to the interests of inventors and patentees everywhere, and is *most dangerous* to those inventions which possess the *highest merit*. What would this Court have said if it had been asked to decide in the Telephone Cases that by the grant of later patents to Dolbear, or to Drawbaugh, or to Edison, or to Gray, and granted while suits for infringement were pending, the Patent Office had made a ruling that the Dolbear, or the Drawbaugh, or the Edison, or the Gray telephone "*did not infringe*" the prior Bell Patent? We mean no disrespect to the Court whose decision we are now calling in question, by saying that, as we understand the law, such a holding is simply revolutionary. If such be the law, then the use of the Patent Office for the purpose of presenting, if not for manufacturing, testimony, to prove an issue upon which the prior patentee cannot be heard on his own behalf, hereby enjoys the highest judicial sanction which it can possibly receive outside of this Court, and in the hands of the infringer, becomes an implement of easy use by which to make in all cases a perfect defense. All he has to do is to apply for and procure at a cost of \$35 a later patent for some further detail of improvement, real or pretended. He can *assert* in his application that his "improvement" or "modification" is not an infringement, etc. As the Patent Office has no jurisdiction of the question of infringement (except, of course, in interference cases, and then only for the purposes of the grant), such assertions in a specification are generally allowed to go unchallenged, and are left for the Courts to pass on. The *claim* is usually scrutinized—

nothing else is (100 U. S., 671, 2). Then, no matter how limited the claim, or how trivial the invention, the later patentee, *by merely getting a patent*, obtains, under the decision now in question, an *ex parte* ruling, not that his device involves merely some patentable additions to, or modifications of, the prior patent, but that it departs so essentially from the *claims* of the prior patent that it does not embody its essential features at all—or, in other words, that it *does not infringe*. By the mere grant of a patent so procured, he would have, under Judge HUGHES' decision, a ruling by the Patent Office of *non-infringement*, which he could properly use as a defense.

Such a defense, so made, has thus been held not merely to raise a *prima facie* presumption that the later patent involves some patentable differences from the prior patent, but that its grant, though not conclusive, is sufficient as a defense, and this ruling has been made by a Court of last resort; and if the error be not corrected, it will work irreparable injury, alarming both in amount and extent, to the most meritorious inventors of our nation—or of the world.

The facts on which this singular decision was made are correctly stated by Judge MORRIS in his decision, and his ruling thereon may properly be quoted here as being substantially correct in its application of the law to those facts. Judge MORRIS (66 F. R., 1006, 1007) says :

“ It is further urged that in a doubtful case the scale
“ should be turned by the fact that, subsequent to the date
“ of the patent in suit, indeed more than two years after the
“ institution of this suit, Patents Nos. 481,134 and 481,135,
“ August 16, 1892, were granted to Boyden for the mechan-
“ ism now used by the defendant.

“ Boyden was entitled to patents for whatever was a
“ patentable novelty in the devices by which he was able to
“ make his valve 22 answer for both service and quick-action
“ work in connection with the restricted passage B, and for
“ any other patentable novelty in the forms of his mechan-
“ ism. The widely different forms in which he has illustrated

“ his devices in the two above-mentioned patents show that,
 “ taking what Westinghouse had discovered and demonstrated
 “ to be the underlying principle of a quick-action brake, a
 “ skillful and inventive mechanic can devise many forms for
 “ applying it.

“ But, in his specification of Patent No. 481,135, Boyden
 “ alleges that his device differs essentially from Westing-
 “ house's Patent No. 360,070, and involves a new mode of
 “ operation. The question whether it does or does not was
 “ the very question then pending in this suit, and, so far as the
 “ Examiner passed upon it, in allowing the specification to
 “ stand, he did so upon the *ex parte* application of Boyden
 “ and unassisted by testimony as to the state of the art at the
 “ date of the Westinghouse Patent, and without testimony as
 “ to the scope of the Westinghouse quick-action invention
 “ and its great importance and merit; and, therefore, with-
 “ out the opportunity of judging whether or not it was a
 “ pioneer invention of a fundamental character, entitled to a
 “ construction co-extensive with the invention, or was simply
 “ a patent for an improvement in a known art, to be restricted
 “ to the form of the device shown in the model and illustra-
 “ tions.

“ The determination of that question is the starting point
 “ in the consideration of the controversy, and, in my judg-
 “ ment, the fact that Westinghouse was the first discoverer
 “ of the vital underlying invention, should turn the scale in
 “ his favor.”

Contrasting with this the ruling made by the appellate tribunal,
 it is respectfully but urgently submitted that an error so gross, and
 in its probable results so fraught with danger to the most meritorious
 inventors known to the law, should not be allowed to pass without
 correction; and this is the only Court where it can be authoritatively
 corrected.

Not only is it true that the Patent Office has no authority to decide or even pass on a question of infringement for the Courts, but it is equally true the Patent Office is not authorized to make or create testimony for the Courts.

While the decision herein complained of does not go to the extent of holding that a Patent Office ruling is *binding* on the courts, and, in fact, says that it is not conclusive, it does give to such ruling an effect which, to say the least, has no foundation in law, and also is highly pernicious. In the sentence next following the clause last quoted, Judge HUGHES says of this Patent Office ruling that it

“takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics.”

It would seem to be almost needless to suggest that if a subsequent improver on a pioneer invention can, by the mere *ex parte* act of procuring a subsequent patent, after being sued, *make or create* “testimony” for himself—and testimony which may “take rank” in a Federal Court as that “*of experts of the highest experience, skill and knowledge in mechanics*,” then one of the great safeguards erected for the protection of patented property is entirely destroyed. *On mechanical questions the law knows no higher testimony than that which is thus defined; and hence, when such testimony is furnished, it cannot successfully be rebutted.*

And if this be a correct statement of the law, then, in patent cases, under the issue of infringement, the Courts will have little to do (except in cases of *manifest* error) but to register and enforce the *ex parte* rulings of the Patent Office.

Miller vs. Eagle Manufacturing Co., 151 U. S., 186, stated the rule that the grant of the later patent merely raised “a *prima facie* presumption” of the existence of a “patentable difference” in the latter patent (p. 208), but in other branches of the case this Court distinctly declined to follow and apply a ruling of the Patent Office as to the existence of patentable difference between two patents issued by the Patent Office (p. 202). The

decision of the Circuit Court of Appeals of the Fourth Circuit goes far beyond any decision of this Court in attributing weight and value to the *ex parte* rulings of the Patent Office.

The decisions heretofore made by this Court are believed to be in strict accord with the views we are seeking to present.

The question arose in *Blanchard vs. Putnam*, 8 Wall., 420. Mr. Justice CLIFFORD, in rendering the opinion of the Court (p. 426), said :

“ Attempts are often made in the trial of patent cases to introduce such collateral issues on the question of infringement, but they are irregular and cannot be sanctioned, as the only proper comparison, on that issue, is of the defendant's machine with that of the plaintiff, as prescribed in the pleadings. What the jury have to determine is, does the machine of the defendant infringe the machine of the plaintiff ; and if it does not, then the defendant is entitled to a verdict ; but if it does infringe the plaintiff's machine, then the plaintiff is entitled to his remedy, and it is no answer to the cause of action to plead or prove that the defendant is the licensee of the owner of another patent, and that his machine is constructed in accordance with that patent.

“ Controversies between litigants in court cannot be completed in that way, nor should the plaintiff be subjected to such outside issues, as he is clearly entitled to a verdict when he has proved that he is the original and first inventor of his improvement, and that the defendant has infringed his patent.”

The present case comes exactly within the rule thus stated in these essential features :

- (1) A pioneer patent to complainant.
- (2) A structure or device made by defendant.
- (3) An issue of infringement raised thereby.
- (4) A later patent under which defendant claims to be working.
- (5) A case for final disposition, not for a preliminary injunction.

Under these facts and conditions, *Blanchard vs. Putnam* says

that the patent under which defendant claims to be working is not admissible in evidence at all *under the issue of infringement*.

Later cases which *look like* modifications of this rule relate, for the most part, if not entirely, either to some side or collateral issue, or else are exceptional in their nature.

In *Boyd vs. Tool Co.*, 158 U. S., 260, neither party was a pioneer, and both applications were pending at the same time—a very different case.

In *Pavement Co. vs. City of Elizabeth*, 4 Fish., 189, cited in *Boyd vs. Tool Co.*, the question arose on a motion for a preliminary injunction. In such proceedings presumptions count as evidence, and hence a patent to defendant is worth something in support of a presumption.

But on final hearing, or in what is practically the final disposition of a case, mere presumptions do not count for much. And even in *Miller vs. Eagle Co.* it was merely referred to as a confirmatory consideration, and then only as of a *prima facie* character.

In *Wollensack vs. Reiher*, 115 U. S., 96, the effect to be given to a Patent Office decision arose under a question of reissue. More than two years had elapsed between the date of the original patent and the date of the reissue. Proofs satisfactory to the Commissioner of Patents had been submitted to the Patent Office, so as to account for the delay, and the Commissioner, being satisfied with those proofs, had granted the reissue. These facts were set up in the bill. Defendant demurred, and the Supreme Court, in sustaining the demurrer, after reciting the facts as above stated—that is, the decisions which had been made on the proofs so submitted—added the following (p. 101):

“But this does not satisfy the law. The question as to whether the delay had been reasonable or unreasonable is for the courts to determine, upon the special circumstances brought to its attention, and it cannot substitute the decision of the Patent Office upon that question for its own.”

Hence, it is believed that the law of *Blanchard vs. Putnam* is still the law of the land. And even if later decisions have

tended to modify it, it has never been modified as applicable in a suit on a pioneer patent, and still further has never been so far modified that a grant of a patent becomes testimony of high rank as establishing non-infringement in a Federal Court, and still more so when the later patent is not procured until more than two years after suit is brought.

It is submitted that the effort to raise *ex parte* departmental decisions practically to the rank of adjudications which are authoritative as "testimony" in Federal Courts of last resort, embodies so great and dangerous an error as to create an unusually urgent call for the intervention of this Court by the exercise of its statutory powers of review.

Fourth Assignment of Variance and Error.

This relates to the force and meaning of the phrase "substantially as set forth," which is appended to claim 2 of 360,070. The ruling therein of the Circuit Court of Appeals for the Fourth Circuit is believed to be directly at variance with the decisions of this Court, and to be in error as matter of law.

The ruling thus assigned for variance and error is formulated or stated by Judge HUGHES as follows (Opinion, pp. 15, 16) :

" The phrase ' substantially as set forth ' is technical, and
 " is equivalent to saying ' by the means described in the text
 " ' of the inventor's application for letters patent, as illustrated
 " ' by the drawings, diagrams and models which accompany
 " ' the application.' These words limit the general terms
 " of the specification which set out the *function* performed
 " by the invention, and confine the inventor's rights to his
 " own *means*, or their mechanical equivalent of performing
 " the function."

It is submitted that in this extract are contained two statements of law, both of which are at variance with the rulings and decisions of this Court.

1. In holding that "substantially as described" is a limiting phrase, not as to the *general combination* of mechanism recited in the claim, but as to elements of mechanism *not* recited in the claim, and which may be varied from without departing from the main invention.

In *Lake Shore & M. S. Co. vs. National Car Brake Shoe Co.*, 110 U. S., 229, 235, this identical question arose, and, under one of the claims in suit, was the main point in controversy. The question is discussed at length (p. 235). We quote three lines, the italics being our own :

"The words 'substantially as specified' mean substantially as specified in regard to *the combination which is the subject of the claim.*"

In *Deering vs. Winona Harvester Works*, 155 U. S., 286, 302, the twentieth claim of the patent in suit was in the following words (p. 290) :

"20. The combination in a grain binder, of moving butt-adjusting mechanism, and the board *d*¹, *substantially as described.*"

The defendants insisted (p. 302) that this 20th claim was invalid because the *means* by which the board *d*¹ was held and controlled in its pivotal connection to the butt-adjuster were "not stated in the claim," or that certain additional elements by which it was described as so held and controlled, must be "read into" the claim, but this Court (as already quoted) decided otherwise, saying (p. 302) :

"Admitting that additional elements are necessary to render the device operative, it does not necessarily follow that the omission of these elements invalidates the claim, or that the precise elements described in the patent as rendering it operative *must* be read into the claim. If Steward were in fact the first to invent the pivotal extension to a butt-adjuster, he is entitled to a patent therefor, though the infringer may make use of other means than those employed by him to operate it (*Loom Co. vs. Higgins*, 105 U.

“ S., 580, 584). In such case any appropriate means for making it operative would be understood. Otherwise, the infringer might take the most important part of a new invention, and, by changing the method of adapting it to the machine to which it is an improvement, avoid the charge of infringement. The invention of a needle with the eye near the point is the basis of all the sewing machines used ; but the methods of operating such a needle are many, and if Howe had been obliged to make his own method a part of every claim in which his needle was an element, his patent would have been practically worthless.”

The decision of Judge HUGHES is directly at variance with this in that it applies this phrase “substantially as described,” to the particular “means” which are merely *supplementary* to the elements of the claim (meaning a particular valve and particular passage way to it, illustrated by Westinghouse), instead of, as it should do, to *the combination* of those elements which are actually recited in the claim.

The same rule of construction is practically embodied in the following extract from the old (1853) case of *Winans vs. Denmead*, 15 How., 330, 342 :

“ It is generally true, when a patentee describes a machine, and then claims it as described, that he is understood to intend to claim, and does by law actually cover, not only the precise forms he had described, but all other forms which embody his invention ; it being a familiar rule that, to copy the principle or mode of operation described is an infringement, although such copy should be totally unlike the original in form or proportions.”

Such has always been the uniform rule in the Federal Courts, especially when dealing with “pioneer” inventions. It is hardly conceivable that the door is now open for the establishment of a different and less favorable rule.

(2) The other variance, or rather error, double in its character, arose from the failure on the part of the Court of Appeals in the

Fourth Circuit to note two important limitations in applying the rule as to "means" and "mechanical equivalents."

(a) As to "means," the inquiry was not limited, as it should have been, to the means which are *essential and substantial to the invention*. This was clearly an error.

(b) As to "mechanical equivalents," the liberal rules of construction repeatedly announced from this Bench as applicable to pioneer inventions, were either overlooked or ignored. Such rulings are too numerous for quotation, but reference may be made to the following leading cases :

Morley Machine Co. vs. Lancaster, 129 U. S., 263, 273.

Clough vs. Barker, 106 U. S., 166, 177.

Consolidated Valve Co. vs. Crosby Valve Co., 113 U. S., 157.

McCormick vs. Talcott, 20 How., 402, 405.

Deering vs. Winona Co., 155 U. S., 206, 302.

Miller vs. Eagle Mfg. Co., 151 U. S., 186, 207.

And for a convenient summing up of the law herein, and for a proper application of such law to a collateral branch of this case, we respectfully refer the Court to the extract, *supra*, pp. 4-6, from the decision in the Court of Appeals in the *Second* Circuit (63 F. R., 969). What is there said under Patent 376,837, is *mutatis mutandis*, applicable in still higher degree under the earlier Patent 360,070.

The correction of these errors is material to the rights of the petitioners herein.

This will amply appear on a brief statement of a few facts.

(1) The Westinghouse Patent No. 360,070, here in suit, is a pioneer patent, or the first of its kind, and is so both confessedly and by all the adjudications yet made thereunder.

(2) Claim 2 of this patent, held valid in one Circuit and invalid in another Circuit, is a claim which is most broad and comprehensive in its terms, and, if valid, will give efficient and ample protection to the actual invention stated therein. If held to be

invalid, so much of the invention as is within its scope, and outside the scope of the remaining claims, will cease to have any protection whatever.

Believing the decision in the Fourth Circuit as to the invalidity of this claim to be in error, and as well at variance with the decision in the Second Circuit, and believing that thereby a valuable and material portion of the Westinghouse "Quick Action" invention is liable to fail in receiving proper and lawful protection, it is submitted, not only that the variance and error are material, but that they are *so* material as to be entitled to corrective relief in this Court.

(3) The adverse rulings made in the opinion of Judge HUGHES as to the effect of the issue of later patents to Boyden, and as to Patent Office rulings generally, bearing directly *on the issue of infringement*, and being so stated by the Court, cannot be otherwise than highly material to the rights of the petitioners herein.

(4) And the same is true as to the limitations imposed on said claim 2, under the phrase "substantially as set forth." But for these limitations the issue of the infringement must have been found in favor of complainants below—the petitioners here. And this will appear from a comparison of defendant's device with the terms of the claim, as well as from Judge MORRIS' opinion rendered in the Court below (66 F. R., 997).

Hence it is submitted that the correction of *these* errors, and without regard to other material errors yet to be noted, will probably, if not necessarily, result in a finding in this Court in favor of the petitioners herein, and a reversal on all the claims of the decision now sought to be reviewed.

Irreparable Injury.

Proper averment of "irreparable injury" to petitioners is made in the "fifteenth" paragraph of statement in the petition for the writ (Petition, pp. 5, 6).

It would seem to go without saying that a case of "irreparable injury" of most serious character was presented, when a Court of last resort (erroneously as is alleged) holds to the invalidity of the claim which, in its terms, appears to afford the best protection to the invention as made, and especially when such holding is in direct conflict with a decision of the same question in another Court, also of last resort, in another circuit.

Still more so when such erroneous decision limits the claim unduly, by reliance on *ex parte* "testimony," created for the purpose, by the procurement of a patent by defendant after the suit was brought.

And still more so, when the decisions of this Court are overlooked or disregarded in imposing, under "substantially as set forth," improper and unauthorized limitations on the claim.

And these considerations acquire still greater cogency in view of the fact that over four hundred thousand cars, passenger and freight, have been equipped in this country with quick action brake apparatus under (as was supposed) the protection, inter alia, of this claim 2 of Patent 360,070. Fully an equal or perhaps a still greater number yet remains to be equipped. And under Act of Congress, such further equipment must be completed by or before January 1st, 1898.

These suggestions apply more or less perfectly under remaining assignments of error, but we insert them here merely as a matter of convenience.

Fifth Assignment of Error.

FIFTH. As further matter of error herein, and as a matter irreconcilably at variance with the ruling of the Circuit Court of Appeals in the First Circuit, your petitioners further submit that manifest error was made by the said Circuit Court of

Appeals for the Fourth Circuit, in holding as matter of law that the mere erasure from the specification as originally filed, of a description of a proposed modification, operates as a disclaimer of such modification.

In the Westinghouse specification as originally filed, a *non-integral* emergency valve was described, and a clause was added to the effect that "the same office is performed by a valve *integral* with the main valve," etc.

The Patent Office, under its rules of practice, required this clause to be erased, for the reason that such an *integral* structure was not illustrated in the drawings. Whether, as a mechanical equivalent, it would come within the terms of the claims as allowed, was a question with which the Patent Office had no concern. The decision of that question belonged to the Courts. The clause in question was erased. Judge HUGHES' opinion, as understood, holds that an *erasure* in law amounts to a *disclaimer*.

This question arose directly in the Court of Appeals, in the Second Circuit, and it was held otherwise.

Reece Button-Hole Machine Co. vs. Globe Button-Hole Machine Co., 21 U. S. App., 244; 10 C. C. A., 194; 61 Fed. Rep., 958.

This Reece case contains probably the fullest discussion this question has ever received. Supreme Court cases are cited in large number and applied or distinguished. The conclusions reached by the Court in the Reece case, seem to be well founded in law, but the discussion is too lengthy for quotation in full. In 61 Fed. Rep., 967-970, will be found the portion of that decision here in point. The reasons there presented are so persuasive that we feel safe in submitting this part of our case thereon.

The remaining assignments of error do not probably contain any matters more imperatively requiring review and correction than those above presented.

Hence we deem it unnecessary to weary the Court with a discussion of them in detail ; and the more so, because of the complicated character of the apparatus in which the invention is embodied, and because of the contradictory character of the testimony. In fact there are, we believe, only two important facts in the case, as to which there is no dispute.

FIRST. The merits and high rank of the Westinghouse invention as a pioneer in this branch of the arts, are not denied.

SECOND. There is no dispute as to the form or construction of defendant's apparatus.

Everything else is denied. The method of operation involved in the orderly movement of the piston and valves of defendant's apparatus, and the relationship of that apparatus to complainant's patent, and to sundry prior patents, are among the chief questions in dispute. And these questions involve sundry matters of fact which cannot be made clear except by oral presentation, or in lieu thereof, by a written treatise on air brakes of such length and fullness that no court can reasonably be asked to read it.

For these reasons, our right to a writ of *certiorari* herein is' submitted on the first five assignments of error. When the cases come up for oral argument, if the Court should so order, we will ask to be heard, if need be, on the matters referred to in the other assignments of error.

In the Supreme Court of the United States.

IN THE MATTER OF THE PETITION

OF

GEORGE WESTINGHOUSE, JR., and THE WEST-
INGHOUSE AIR BRAKE COMPANY for a Writ of
Certiorari.

Reply to the Brief for the Boyden Brake Company.

His Honor the Chief-Justice was understood to say to counsel, at the time the motion was submitted, that, if the Boyden brief presented anything new, a reply thereto could be made.

The brief, as submitted, is believed to contain one or two matters of this kind.

1. It is contended in the Boyden brief that the suit is not one of peculiar gravity and general importance, for the reason that the *invention* of Patent No. 360,070 is not of *such* importance as the petitioners allege.

In support of this the Boyden brief asserts, in substance, that the invention of the patent in suit, No. 360,070, is not in use, either upon 400,000 freight cars or otherwise, "and has not been made since 1887." Brief, page 8, is thoroughly misleading, as are also the quotations from page 224 of the record.

What was asked of Mr. Westinghouse in those questions was whether the Westinghouse Company's catalogue for 1890 contained illustrations of their quick-action brake "like that shown in the

"drawings of the Letters Patent No. 360,070," or whether the company were *now* making or selling brakes of the type or form "shown in the drawings" of said patent.

This testimony is distorted from its actual meaning, which was, merely, that the Westinghouse Company were not now making *the particular form* of the invention shown in the drawings, into a statement that they were not utilizing *the invention itself*, which, being of a primary character, was capable of embodiment and expression in a number of forms.

The record abundantly shows that the Westinghouse Company are now manufacturing, and have been manufacturing since 1887, brakes which embody the invention of their Patent No. 360,070, and are based upon that invention, although, as in the case of all progressive manufactures, the form in which the invention is embodied has undergone development and change, and has been modified by the introduction of supplementary improvements, of which that of Patent No. 376,837 is of great importance.

This state of facts clearly appears by the decisions of the Courts to which reference has been made, and an attempt to make it appear otherwise in the brief of the Boyden Brake Company is hardly fair.

The statements contained in our original petition are strictly correct.

2. Again, in order to explain away the conflict of opinion between the appellate Courts in the two circuits, as to the validity of the second claim of 360,070, the Boyden brief relies on the differences between the alleged infringing structures.

This has to do with the issue of infringement—not with the issue of the validity of the patent.

While there were important differences of structure between the infringements complained of in the two cases, yet the Circuit Court of Appeals for the Fourth Circuit went far beyond the point of merely deciding upon these differences. It is true that it adverted to the difference between the two structures in the two concluding clauses of its opinion as a reason why it did not regard the opinion

of the Circuit Court of Appeals for the Second Circuit as controlling upon it, but it went much further than this, and expressly held, in the passages cited in our petition and in the accompanying brief, that the second claim was invalid, or, as stated, "fatally defective," because functional in character, and because it omitted necessary elements to make its combination complete.

The claim, on its face, clearly, in terms, covered the defendant's structure in the case in the Fourth Circuit. The Court got rid of its effect by holding that it was "fatally defective."

This was the real gist of the decision, and the basis of the opinion of the Court.

The reference to the difference of the structure before it and that before the Court for the Second Circuit was merely cited as a reason for not following the decision of that Court upon a point which they had already decided upon other grounds, which other grounds involve, as we submit, a clear conflict of opinion between the two Circuit Courts of Appeal.

In a case of the importance of the present one, where the invention is in use, and largely in use, in every circuit of the United States (as is shown in our petition and principal brief), it is essential that decisions so palpably in opposition to each other upon a fundamental point should be subject to the review of this Court. Other suits are pending in still other circuits (as shown by our petition) against still other forms of apparatus, and the validity of the second claim of the Westinghouse Patent No. 360,070 is a fundamental question in those suits, preliminary to the consideration of any question of infringement whatever.

That question can only be settled for the whole country by this Court.

This probably brings us to the limit of the permission granted us to reply. But it is believed that the other points of the Boyden brief, or most of them, are sufficiently discussed in our original brief.

ANSWER

of the Westinghouse Air Brake Company and George Westinghouse, Jr. (complainants at Circuit), to the petition of Boyden Power Brake Company et al. (defendants at Circuit).

In answer to the petition filed by the Boyden Brake Company *in re* motion to advance the hearing of the above-entitled causes, the Westinghouse Air Brake Company and Geo. Westinghouse, Jr., through their counsel, submit the following as their reply :

They have no objection to an early argument of the cases. But they do not understand that under Rule 26 they have any right to an advance, and, hence, they have not formally united in the application. It is a case between private parties solely. It is not a *criminal* case, nor a *revenue* case, nor a case in which the United States is concerned. But if, in the opinion of the Court, the cases involve or affect some matter of such general public interest that they ought to take precedence of other cases which have been still longer pending between private parties, then these repliants have no objection to their being advanced so as to be heard at some convenient time during the next ensuing term of the Court.

It would be practically impossible to get the record printed and proper briefs prepared under the rules before the probable end of the present term. The record contains over 1,400 pages of matter in book form, and includes a large number of drawings which would have to be reproduced by photo-lithography.

The general facts recited in the petition are stated purely from the Boyden standpoint, and for the most part, where material, are erroneous or misleading. These errors and misleading statements made are too numerous to be reviewed in a short reply.

Fact and fallacy are so dexterously intertwined in the petition that to separate them would unduly lengthen this reply.

Briefly summarized, the reasons alleged in support of the petition are as follows :

1st. The questions involved are of "*great public importance.*"

2d. The case involves only *one* question, *that of infringement*, and hence can be readily disposed of by the Court with "*no unusual amount of labor.*"

3d. The Boyden Co., partly as the result of an injunction and partly as the result of competition, has been kept out of a highly lucrative business for six years.

4th. Under Act of Congress of March 3d, 1896, Chapter 196, the business for which the Boyden Co. was organized will all be done by or before January 1st, 1898, and hence it should be allowed an early chance at the business.

5th. The defendant company has a patent, and in consequence of this litigation has been deprived of nearly four years' enjoyment of the seventeen years' privilege thus accorded to it, and it would be grossly unjust if such deprivation be continued for one or two years longer.

It is believed that every fact or alleged fact contained in the twelve pages of the printed petition comes under one or another of these five heads.

We will consider them separately :

1st. That the questions involved are of "*great public importance.*"

Several questions are involved which *vary* in importance.

(1) The question of *infringement*—that is, does the Boyden

device infringe the Westinghouse Patent—is (outside of the parties) of considerable importance to railway and transportation companies, but only indirectly so to the public at large.

(2) The Court of Appeals in the Fourth Circuit held that claim 2 of the patent in suit was “fatally defective.”

The Court of Appeals in the First Circuit, in another case, held that this claim 2 was valid.

Both actions of the Court are still in force, each in its own jurisdiction.

The claim as to which these contradictory decisions were made is the claim which, as is believed, in some respects best expresses, sums up and covers one of the essential mechanical features and combinations of operative mechanism which constitutes the “pioneer” or basic invention here in question.

This is *the* question which is raised under our first assignment of error. It is a question which (outside of the parties) is of considerable importance to railway and transportation companies, but only indirectly so to the public at large.

(3) The question raised by our second assignment of error as to the validity of the claim last referred to, as matter of law, has the same extent and limitations of public interest.

(4) The next assignment of error involves a question which is of general importance to all inventors, patentees and to all owners of patent property, and hence is of general *public* importance, in so far as *they* constitute or represent *the public*.

After the suit was brought the Boyden Company procured, in Boyden's name, a patent in which it was stated, in effect, that the Boyden invention was *substantially different* from that of Westinghouse. The proceedings under the Boyden application were wholly *ex parte*, Westinghouse being in no way heard or represented, or even notified.

The Court of Appeals in the Fourth Circuit, in the opinion which was filed, inadvertently fell into numerous errors as to matters of fact connected with Patent Office practice, but also made still more serious errors of law in holding that this action

of the Patent Office was "in effect a ruling that the Boyden "device did not infringe Westinghouse quick-action patent "number 360,070," that being the patent in suit, and, still further, was equally erroneous in its law when it said that "that "ruling takes rank here as the testimony of experts of the "highest experience, skill and knowledge in mechanics."

This is, we believe, the only question pending in this case which is of any *greater* importance to the *public* outside of railway and transportation companies than the questions which ordinarily arise in patent cases.

(5) The fourth and fifth assignments of error—the fourth as to the meaning of "substantially as described," and the fifth as to the effect of a mere erasure from a specification—are also of importance to inventors and patentees, but not more so to the public at large than is usual in patent causes, when similar questions arise.

Of course, all these questions are of exceedingly *great importance* to the parties themselves.

2d. The next point of the petition, as we have summarized it, is that this case involves only *one* question, that of *infringement*, and, hence, can be readily disposed of by the Court with "*no unusual amount of labor.*"

Thus, at the top of page 12, of the petition, it is said :

"No question of prior invention, anticipation or public use "is raised, but simply the question of infringement."

Our reply is :

(1) It does not require a record of 1,400 book pages to present simply *one* question of infringement.

(2) The conflicting opinions of two Circuit Courts of Appeals are to be dealt with.

(3) The validity of the second claim of the patent in suit, held valid in the Second Circuit, and invalid in the Fourth, is to be dealt with.

(4) The effort to make it appear that in the Circuit Court of Appeals for the Fourth Circuit, the invalidity of the second claim of the patent in suit was only *conditional* invalidity—that is, that the Court did not mean what it said—is not borne out by the record.

In the first place, the Boyden Company, in their answer, Record, page 9, paragraph 7, distinctly and unqualifiedly averred (referring to the patent sued on), that “the second claim is invalid, and should not have been granted.” Hence, by their own act, they made *this* one of the issues in the case.

In the next place, in the brief of the Boyden counsel in the Court of Appeals, a special section was headed with the following title :

“THE SECOND CLAIM IS VOID AS BEING FOR A FUNCTION AND NOT FOR A MECHANISM.”

Four pages of the brief (pp. 42-45), were exclusively devoted to maintaining the proposition stated in this heading, and no less than fifteen citations were made.

In the oral argument in the Court of Appeals (stenographically reported) one of the counsel for the Boyden Company introduced this part of his argument with the following words :

“Now, in the brief, and my time is so limited that I shall not take up the time to argue it orally, I ask your Honors to look at pages 42 to 45 of our main brief, which argues fully the question of the second claim being for a function and not a mechanism, and, therefore, void under the ruling in *O'Reilly vs. Morse*.”

This also is a question in the case, outside of infringement. For it is conceded on all hands that if the claim be construed as it reads, infringement cannot be denied. And this is the reason why the Boyden Co. elected to make an issue of the validity of this claim.

(5) And still further, the attack on the validity of this claim is the cause of the larger part of the 1,400 book pages of record. The Boyden Co. set up in defense and offered in evidence a large number of prior patents, English and American, and experted them through hundreds of pages, and made and presented in evidence experimental constructions of some of them, in order, if possible, to detract from the merits of the invention in controversy, and to show that Westinghouse, under the patent in question, was not entitled to the benefits of the doctrine of pioneership which had been so overwhelmingly granted to him by the Court of Appeals in the Second Circuit.

Hence, the position of Westinghouse as a pioneer in the art is one which, under the proofs, will necessarily involve here, as in every case thus far argued, an amount of labor on the part of the Court much in excess of that which is usual in patent cases.

(6) The petition fairly bristles with statements which involve issues here in controversy.

Thus, the statement of the nature of the Westinghouse invention here in question, as found in the middle of page 3, is wholly misleading. In fact, the scope of the invention is one of the chief issues of the case.

So, in the first paragraph of page 4, the question as to whether Mr. Boyden "invented another and radically different" means for accomplishing the same result is one of the contested issues in the cause. What is there said on this subject is merely a statement of the Boyden position, while, according to the Westinghouse contention, the reverse is the case.

Several other misleading statements of like kind could easily be pointed out, if time and space permitted.

(7) The argument before Judge MORRIS at Circuit occupied four days. In the Court of Appeals two days were allowed, and the second day was extended beyond the usual hour for

adjournment. Both Courts found that "an unusual amount of labor" was involved.

Printed briefs and arguments submitted to the Court of Appeals when added up amount to *four hundred and thirty-six pages*. And all for what, in the Boyden Petitions, is alleged to be "simply the question of infringement!"

(8) The Boyden appeal includes *eighteen* assignments of error (Rec., pp. 1379-1381), which was certainly rather a large number on which to take up to the Court of Appeals "simply the question of infringement."

And the Westinghouse case went up to the Court of Appeals on *seven* assignments of error, and comes into this Court with *twelve more*.

Hence, it is believed that the petition somewhat understates the facts when it says that "simply the question of infringement" is involved, and that the cases will involve "no unusual amount of labor."

3d. The next point of our summary of the Boyden petition is that the Boyden Company, partly as a result of an injunction, and partly as a result of competition, has been kept out of a highly lucrative business now for six years.

Our reply is :

(1) If it is lucrative, the Westinghouse Company has made it so, and that is why it has had to raise and invest \$5,000,000 of capital, so as to be able to supply the demand which it has created.

(2) The railway companies are not complaining of excessive charges for brake apparatus.

(3) In so far as by lawful and proper competition, the Boyden Company may have been kept out of business for the past six years, the petition states no groundwork for the special interference of this Court.

(4) It is not true as represented on page 5 of the Boyden petition, that the Boyden Company and its co-petitioners were

ever under injunction. While an injunction was allowed, none was ever issued. If the petitioners ever discontinued business, they did it either voluntarily, or else because they made a brake apparatus which nobody would buy.

(5) And as the petition has traveled largely outside the record, we may be permitted also to go outside so far as to say that with the growth of the art, the Boyden device involved in this case has so far ceased to be in demand that the manufacture thereof was discontinued long ago, and the Boyden Co. is now seeking to introduce and sell a device *differing in material respects* from the one here in controversy. Hence, the question of infringement *as thus raised* is no longer a question of importance even *to the Boyden Company*—though it is to us—involving, as it does, the scope and validity of our patent.

4th. The fourth clause of our summary of the petition is to the effect that under Act of Congress, Chapter 196, the air brake business must all be done by or before January 1st, 1898.

(1) The Act of Congress referred to on page 6 of the petition (Act of March 3, 1893, Section 1 of Chapter 196) does not require, as cited in the petition, that “all railroads engaged in interstate commerce must be fully equipped with power brakes on or before the 1st day of January, 1898, or suffer a heavy penalty.” The section referred to reads as follows, and we italicise seven words:

“That from and after the first day of January, 1898, it shall be unlawful for any common carrier engaged in interstate commerce by railroad to use on its line any locomotive engine in moving intersate traffic not equipped with a power-driving wheel-brake and appliances for operating the train-brake system, or to run any train in such traffic after said date that has not *a sufficient number* of cars in it so equipped with power or train brakes that the engineer on the locomotive

drawing such train *can control its speed* without requiring brakemen to use the common hand-brake for that purpose."

Hence, all the act requires is that within the next two years *enough* cars must be equipped with power brakes so the train can be *controlled by the engineer*, which is a very different thing from saying that *all* must be so equipped.

Hence, in the orderly course of events, these cases will be reached and disposed of long before *all* the freight cars of the country will have been equipped with power brakes.

(2) Whether the Westinghouse Company can furnish air-brake equipment within the next two years for all freight cars which now are not equipped is a matter wholly outside the record, but we are authorized to say that the Westinghouse Company can supply such equipment to all the railways of the United States as rapidly as, with their present shop facilities, the railway companies can put them on. Hence, the railway companies will not suffer if these cases stand till reached on regular call.

(3) The air brake business will not end January 1st, 1898, as the petition seems to apprehend. In round numbers, there are about forty to fifty thousand new cars built in this country every year, and the number is more likely to increase than diminish. After this case is reached and disposed of on the regular call of the docket, if the result be favorable to the Boyden Co., it will find plenty of business still to be done.

5th. The Boyden Company also says that it has a patent, and in consequence of this litigation, has been deprived of nearly four years' enjoyment of it, and that it would be unjust if such deprivation be continued for one or two years longer.

This is wholly fallacious.

The taking of a patent does not grant to the patentee any right to make, use and sell, *which did not belong to him before the patent was granted*. The patent merely grants to the pat-

entee the right *to forbid others* from making, using or selling the thing patented. *This right of prohibition* granted to Boyden by his patent, he and his company have fully enjoyed ever since the date of the patent, and they are enjoying it yet. Hence, in this regard, the Boyden Company is not suffering any hardship of which they have any right to complain in this Court.

Respectfully submitted,

GEORGE H. CHRISTY,

FREDERIC H. BETTS,

Counsel for the Westinghouse Air Brake Co., &c.

Supreme Court of the United States.

AIR BRAKE COMPANY,
COMPLAINANTS AND APPELLEES.

No. 426.

GEORGE WESTINGHOUSE, JR., and THE WESTINGHOUSE
AIR BRAKE COMPANY,
COMPLAINANTS AND APPELLANTS,

VS.

BOYDEN POWER BRAKE CO. ET AL.,
DEFENDANTS AND APPELLEES.

BRIEF FOR WESTINGHOUSE.

Suit was brought in the U. S. Circuit Court for the District of Maryland by Westinghouse and The Westinghouse Air Brake Company, by bill in equity in the usual form, for infringement of the Westinghouse Patent No. 360,070, claims 1, 2 and 4.

Decision by MORRIS, J., was in favor of complainants under claim 2, that the claim was valid and was infringed, but adverse under the other two claims, the Court finding non-infringement as to these claims (Opinion, Rec., p. 842).

Each party appealed from so much of the decree as was adverse.

The decision of the Court of Appeals for the Fourth Circuit was adverse to complainants on all points, holding that the first and fourth claims of the Patent in suit were not infringed, and that the *second* claim was "fatally defective" (Rec., pp. 869-883). This opinion, as to the second claim, was in conflict with the decision of the Court of Appeals in the Second Circuit, sustaining the validity of the same patent, and was also believed to contain substantial error, both of fact and of law, which resulted in the decision of non-infringement of the other claims. Hence, the proceedings which resulted in the issue by this Court of a writ of *certiorari* (Rec., p. 890), and by which the cause is now here for review.

Assignments of Error.

The assignments of variance and error set forth in the petition for writ of *certiorari* are as follows, so far as is necessary to present the questions here urged :

FIRST. As to the validity of claim 2 of the patent in suit, No. 360,070, as matter of law, on the face of such claim, the decision of the Court of Appeals for the Fourth Circuit is, in terms, and apparently in scope and effect, irreconcilably at variance with the holding of the U. S. Circuit Court of Appeals for the Second Circuit.

And herein your petitioners submit the following extract from the opinion of the Court of Appeals for the Fourth Circuit, in the cases Nos. 131 and 134, now sought to be brought before your Honorable Court by writ of *certiorari* :

" We think that when claim 2 of 360,070, in its language describing the action of that device, failed to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston ' by a further traverse, admits air directly from the main

air pipe to the brake-cylinder,' it was fatally defective, claiming only a result which is public property, and not identifying the specific means (his own property) by which the result is achieved."

In the Court of Appeals in the Second Circuit, this claim 2 of Patent 360,070 was held to be valid.

SECOND. As a matter of error herein, your petitioners submit that the said decision of the said Circuit Court of Appeals for the Fourth Circuit, that said claim 2 of Patent No. 360,070 is "fatally defective" in matter of form, or in the substance thereof, is not well founded in fact or in law.

THIRD. As further matter of error herein, your petitioners respectfully submit that manifest error was made by the said Circuit Court of Appeals for the Fourth Circuit, in its rulings as to the effect of the proceedings in, and action of, the U. S. Patent Office, and herein:

(1) That error was made in holding as matter of law or fact, without proof, that the said Patent Office "employs the best experts in mechanics which it can secure in this and other countries."

(2) That error of fact was made in holding that the examinations made in the U. S. Patent Office, though "*ex parte* in form," are "nevertheless conducted under hot and skillful contestation in every case of importance."

(3) That, possibly by these errors of fact, error of law was made wherein it was held by the said Court that, in granting a later patent to Boyden, without notice of any kind, "that action by the Office was in effect a ruling that the Boyden device did not infringe Westinghouse Patent here in suit, No. 360,070."

(4) Further error was made in holding, as a matter of evidence, that "that ruling [of the Patent Office] takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics."

FOURTH. And, as matter of error and variance herein, your petitioners respectfully represent that the force and meaning of the phrase

"substantially as set forth," as explained and applied by the said Circuit Court of Appeals for the Fourth Circuit, is directly at variance with the decisions of this Court, and is in error as matter of law.

FIFTH. As further matter of error herein, and as a matter irreconcilably at variance with the ruling of the Circuit Court of Appeals in the First Circuit, your petitioners further submit that manifest error was made by the said Circuit Court of Appeals for the Fourth Circuit in holding, as matter of law, that *the mere erasure*, from the original specification, of a description of a proposed modification operates as a *disclaimer* of such modification.

SIXTH (original Eighth). The Court erred in holding that defendants' apparatus was not an infringement of claims 1, 2 and 4 of complainant's patent, and each of them.

As a further assignment of error (included in the original assignment of error before the Court of Appeals, Record, p. 862) we say :

SEVENTH. The Circuit Court of Appeals erred in not holding each of the claims Nos. 1, 2 and 4 of Patent No. 360,070 valid and infringed by the defendants.

These original assignments of error involve, in one form or another, the following material issues :

1. As to the *character, originality and extent* of the invention as made.

2. *As to the scope and proper construction of the Patent 360,070 granted therefor.*

The *validity* of the patent is not contested in the proofs, and the answer denies it only *pro forma*.

3. As to infringement.

As sub-heads, under the three issues thus stated, and collateral thereto, are the following :

4. The effect on Patent 360,070 of certain proceedings in the Patent Office in connection with the application therefor.

5. The effect of a patent granted to defendants, which was applied for *after* the suit was brought—all proceedings therein being *ex parte*.

It is believed that under the foregoing may be included all the questions, the consideration of which is desired in the present proceedings.

History of the Westinghouse Air Brake.

The Westinghouse air brake has been developed through three forms or types, and the invention here in question relates to the perfected results.

The earliest form or type of the Westinghouse brake is referred to herein as the "plain" or "straight-air" brake.

The second type is that known as the "automatic" brake.

The third or final type is that known as the "quick action" or "emergency" brake. This final type of brake is the one patented in the patent in suit.

That Westinghouse invented them all—the "plain" or "straight-air," the "automatic" and the "quick-action" as well—is not denied.

Practically, he *created* the art of controlling the movements of trains by fluid pressure, and has also *perfected* it.

His exclusive right to the "plain" brake was established in *Westinghouse vs. Gardner & Ranson Co.*, 9 Pat. Off. Gaz., 538.

His exclusive right to the "automatic" brake never became a matter of litigation.

His exclusive right to the "quick-action" brake has been repeatedly affirmed, and affirmed in every case where the question has arisen.

In the present case, the Court of Appeals for the Fourth Circuit do not *deny* the right; they were of opinion that one claim was

"fatally defective," and the others *too limited* to embrace the defendants'.

In both these points, we submit they were in error.

A brief statement of the salient features of these three brakes will aid materially in an understanding of the present issues.

THE "PLAIN" OR "STRAIGHT-AIR" BRAKE.

In this there was an air-compressing pump, operated by steam from the locomotive boiler, by means of which air was compressed into a comparatively large reservoir, to a pressure of about eighty pounds per square inch. This reservoir, being still used, is now known as the "*main*" reservoir. From it an air pipe, sometimes called a "train pipe" led up into the cab, through the "*Engineer's Valve*," and thence down and *back* under the tender and cars, being united *between* cars, by India-rubber hose and metal couplings. These couplings were, and still are "automatically detachable;" that is, while they kept their grip or hold on each other, under the strains incident to the ordinary running of the train, they would readily pull apart under unusual or abnormal strains—as when a car coupling broke, and the train pulled in two.

Each car had a "Brake Cylinder," which contained a piston, the stem of which made connection with the ordinary brake levers. The piston was moved, so as to apply the brakes, by means of air pressure admitted into the forward end of the brake-cylinder, through a branch from the "main air" or "train" pipe.

A valve known as the "Engineer's Valve" was inserted in the line of this air (or train) pipe in the cab, and within easy reach of the engineer. When the brakes were to be applied the engineer shifted this valve so as to let the compressed air flow from the main reservoir back through the train pipe into the brake cylinders of the several cars, so as thereby to push back the pistons, actuate the brake levers and apply the brakes.

To release the brakes, he reversed his engineer's valve, and let

the compressed air escape from the brake cylinders by flowing forward along the train pipe to the escape port of the engineer's valve, and thence out to the atmosphere.

To "slow down," or hold his train in check and under control on a long down grade, the engineer made what may be called a *partial* application of the brakes. He admitted, say twenty, thirty or forty pounds of pressure to the brake cylinders—just as much or as little as he found to be necessary—and then *closed* his valve, so as to *hold that pressure*, without increase or diminution, till the occasion for slow speed was passed, or the foot of the grade was reached. This is commonly called "*graduating*." It means operating the brakes with a "*graduated*" pressure, or a pressure *less than the maximum*.

Hence, with the "plain" brake, if the engineer wished to stop *quickly*, he turned on the *full pressure* of eighty pounds, and turned it on as rapidly as he could make it effective.

If he wished to stop *slowly*, he turned on the pressure slowly.

If he wished to "graduate," that is to "slow down" without stopping, he turned on only a part of the pressure, much or little, as he might think necessary.

All three, that is a "quick" stop, a "slow" stop, or "graduating"—slowing down with *no* stop—all involved the same operation. In each and every case air pressure *direct from the main reservoir on the locomotive* was admitted to force forward the piston of the brake cylinder under each car, and so apply the brakes. As between the "quick stop," "slow stop" or "graduating" action, there was only a question of degree.

These were the leading appliances which made up the "plain" brake, as involved in *Westinghouse vs. G. & R. Co.*, 9 O. G., 538.

The Court of Appeals correctly described this brake in their "statement" accompanying the opinion (Rec., p. 870).

THE WESTINGHOUSE "AUTOMATIC" BRAKE.

The "plain" brake answered its purpose in passenger car use for some years, but certain exigencies were encountered, in railway train service, which it failed to meet.

1st. For the stopping of trains it was sometimes too slow. The time required for the flow of *enough* air, even under high pressure, from the main reservoir on the locomotive, back to each of the successive brake cylinders of the train, and especially to the *last* ones, was considerable; it averaged fully *one second per car*. A train moving at the not unusual speed of fifty miles an hour is going over seventy feet per second. Hence, with the "plain" brake on a ten-car train, an engineer could not, even in the most alarming emergency, get the brakeshoes into any effective contact with *all* the wheels until his train had run a little more than one-seventh of a mile, and it was *after that* that the braking or stopping had to be done. It was of the highest importance, in times of impending danger, to save the ten seconds thus wasted while running that one-seventh of a mile.

2d. It depended for operation on air pressure *from the locomotive*. Trains meet with accidents. A car coupling breaks and the train pulls in two. While the engineer may easily, with the "plain" brake, stop the *forward* portion, or the section which remains connected to the locomotive, how is the rear portion to be stopped so as to avoid a dangerous collision by running into the front portion? This was an exigency or emergency for which the "plain" brake made no provision.

These with other defects or imperfections led Mr. Westinghouse to the invention of the "automatic" brake. How did he do it?

Retaining nearly all the mechanism which belonged to the "plain" brake, he altered radically its method of operation, and he added to it two mechanisms which largely remedied the defects above noted.

FIRST. He put *under each car* an air reservoir of sufficient capac-

ity to hold at least enough compressed air for *one operation of the brakes of that car*. Hence, when he wished to apply the brakes, the air necessary for doing the work was already present on, and distributed along, the several cars, and the delay of transmitting it back from the main reservoir on the locomotive through the long train pipe was wholly avoided. This saved the ten seconds, more or less, of time above referred to.

And as this car reservoir was *auxiliary* to the *main* reservoir it came to be known as the "auxiliary reservoir," and is so designated in the testimony herein.

SECOND. The other mechanism which Mr. Westinghouse added to the "plain" brake, so as to produce the "automatic," consists of what was then termed, and is still known as, a "triple valve," so called because, inserted at the junction of three pipes, it automatically controls the orderly flow of compressed air in three directions, by opening and closing, at proper times, three ports or valve openings, and thereby automatically effects or secures the orderly actions of the brake.

These three ports or valves are :

1. A port or valve from the train pipe to the auxiliary reservoir. This allowed the auxiliary reservoir to fill so as to be *ready* to apply brakes.

2. A port or valve from the auxiliary reservoir to the brake cylinder. This allowed flow of air to apply brakes and was called the "main valve" of the triple.

3. A port or valve from the brake cylinder to the open air. This caused the brakes to become or remain *released*.

A *considerable variety* of forms of these triple valves have been invented by Westinghouse and others, but their essential features are as above described.

The better to illustrate a "triple valve," reference may be made to the first drawing facing Record page 468, "Complainants' Exhibit Illustration Automatic Brake System," and to the middle section, marked "Ordinary Triple Valve." The three pipes entering the casing of the triple valve will be easily identified—the first coming up from the train pipe below, the second, on the left, leading to "Auxiliary Reservoir," and the third going upward to "8-in. Brake Cylinder."

With this "Automatic" apparatus, before the train starts, air pressure from the main reservoir is permitted to flow back through the train pipe. This pressure, entering the "triple valves" on all the cars (each car having its own "triple valve"), automatically shifts their moving parts so as to open the ports and passages which lead from the train pipe to the auxiliary reservoirs on all the cars, and so *charges them with full working pressure.*

This operation may be illustrated by the use of the triple valve of Westinghouse Patent 168,359 (Rec., p. 752), merely changing, for greater clearness of illustration, the plane of the auxiliary reservoir connection from the side to the top of the case.

As will be seen, by examining the sketches, Nos. 90 and 91, opposite the following page, there are two positions of a "triple valve," by which three valvular openings or passages, for the admission or exclusion of the flow of air, are brought into action. The yellow line, sketch No. 90, shows the flow of air in the charging operation—*i. e.*, while the auxiliary reservoirs are filling up—and this position is the one which the parts maintain while the train is running, or in running order, and the brakes are "off."

This line of flow, or line of passages and ports through the triple valve, may, for convenience, be designated as *Passageway No. 1.* The port or valve which is opened is one which connects the *train pipe* with the *auxiliary reservoir.*

The second line of flow is from *brake cylinder* to the *external atmosphere.* This is also open when the auxiliary reservoir is being filled and when the train is in running order and the brakes are "off." It is indicated, in sketch No. 90, by the green line, and when

Automatic Triple Valve: Release Position.

Sketch No. 90.

Automatic Triple Valve: Service Position.

Sketch No. 91.

opened *releases* the brakes, and while open, keeps the brakes released, by keeping open a port or passage to the external air from the brake cylinder.

The third line of flow comes into use when the brakes are *to be applied*. The engineer then shifts his engineer's valve (not the "triple"), so as to let air *escape from the train pipe to the atmosphere*, at the engine. Then the higher, *unreduced* pressure in the auxiliary reservoir, acting backwardly, will operate the moving parts of the triple valve so as to close the port and passage leading back to the train pipe (Passageway No. 1), and close also the port or passage from the brake cylinder to the external air (Passageway No. 2), and *open* the port and passage which leads through the triple valve from the *auxiliary reservoir* to the *brake cylinder* (Passageway No. 3).

This (Passageway No. 3) is illustrated by the red line in Sketch No. 91, which represents the position of the triple-valve devices when the brakes are applied.

Passage No. 1 (Yellow line, Sketch No. 90) is closed by the back stroke of the triple-valve piston, in passing and cutting off the feed ports 51.

Passage No. 2 (Green line, Sketch No. 90) is also closed by the same movement—viz., by the valve H—cutting off the exhaust port 34.

But Passageway No. 3, indicated by a red line in Sketch No. 91, is now opened, so that compressed air may flow from each auxiliary reservoir to its own brake cylinder, and so apply the brakes.

The compressed air which thus flows from the auxiliary reservoirs to the brake cylinders constitutes the entire breaking force in the "automatic" brake which we are now describing.

As it has to flow but a short distance, it is subjected to little friction and gives greater speed of action than was obtained when the pressure had to be transmitted all the way back from the main reservoir on the engine, which was one serious defect of the "plain" brake.

In other words, it saved a large part of the ten seconds of time required in a ten-car train to do the preliminary work of bringing the brake-shoes into contact with the wheels, and thus saved nearly

the whole of the one-seventh of a mile of travel or distance previously lost, as above stated.

So much was saved as regards promptitude in getting the brakes at work.

How or why was it called "Automatic" ?

The brakes in this system are brought into action, primarily, by a *reduction*, at the locomotive, of train-pipe pressure. The engineer shifts his engineer's valve *at the engine*, so as to *vent* or *exhaust* pressure from the train pipe to the atmosphere *there*.

But it will be readily understood that if a train should pull in two, or a car become detached, the same escape of air occurs, and the same action takes place *automatically*, at the broken part, and the same result follows. Train-pipe air escapes through the separated couplings, back pressure from the auxiliary reservoirs shifts the moving parts of the triple valves, so as to apply the brakes, by *automatic action*, in the same way.

The "Automatic" brake is correctly described in the "statement" of the Court of Appeals (Rec., p. 871).

The "Automatic" brake, as thus organized, differed essentially from the "plain" or "straight" brake in its method of operation. Instead of being operated by charging pressure into the train-pipe, it was put into operation by *discharging pressure from* the train-pipe, and by such discharge of train-pipe pressure, or by merely *lessening* such pressure, the triple valves were shifted so as to charge pressure from the *auxiliary reservoirs* into the brake cylinders, and so apply the brakes.

This was wholly new with Mr. Westinghouse. It was a novelty in the mechanic arts, and, in fact, something of a paradox. But it was one of the fundamental principles of the "Automatic" brake, and gave to it, in large measure, its great success. For several years it was the standard brake of the world, and as an element or part of the "Quick-Action" apparatus, it is still a standard, conformed to and adopted by all builders of fluid-pressure train brakes.

DEFECTS OF THE AUTOMATIC BRAKE.

Such, in a general way, and omitting some details not important in the present case, was and is the Westinghouse "automatic" brake, as it has been in use now for many years in the passenger car service of nearly all the railways in this country. The results of its use in passenger trains were so beneficial, and aided so greatly in the safe and expeditious handling of the train, that, as the passenger trains became equipped, railway managers bestirred themselves with reference to securing its benefits in freight-car service.

But, here, new and unexpected difficulties were encountered.

In the development of the business of transporting freight for long distances, and especially on roads having low grades, the tendency has long been in the direction of increasing the load. This has been done, partly, by building stronger and heavier cars, and, as a result of the building of larger and stronger locomotives, capable of hauling a greater number of cars, partly, by increasing the length of trains, so that they are composed of from thirty to fifty cars, or more. Hence, when the Master Car Builders Association of the United States undertook the solution of the problem of applying power brakes to freight trains, or rather, when they called, as they did, on the manufacturers of train-brake apparatus to solve that problem for them, they prescribed, as one of the essential features which such a brake must possess, that it must be capable of operating successfully, and *in all the exigencies of use, both ordinary and extraordinary, heavy and long trains, say of fifty cars.* This gives a train length of over one-third of a mile, or so nearly *one-half of a mile* that practically it may be called that (Westinghouse, Rec., p. 117, Q. 47).

On such a train, the exigency arose for still quicker action than any which had yet been contemplated. Necessarily, the longer and heavier the train, the quicker is it necessary to exert the full pressure of the brakes; and the longer the train the greater the rapidity required in successive action from car to car. Now, while it is true that, on a passenger train of six, eight or ten cars,

the difference in time between the application of the automatic brake upon the first and last cars is so small as to be practically inappreciable, yet, when we come to a train of thirty or *fifty* cars, it is found that in *emergencies, when "quick action" is required, this interval of time becomes so great that the comparative speedy action of the automatic brake was insufficient, and failed to solve that part of the problem.*

For the ordinary work of braking—that is, for lessening the speed of a train while running, and for holding a train in check on a down grade, as also for making ordinary "station stops," as they are called—substantially the same "automatic" apparatus, which had long been employed in passenger train service, was equally applicable, and with satisfactory results, in the equipment of freight trains, even to the extent of *fifty cars in a single train.*

But it was found that when, as in the presence of a great and immediately impending danger, it became necessary to stop a very long and heavy freight train *in the shortest possible time and distance,* and when, for that purpose, the maximum braking pressure was to be brought into practical operation with the utmost celerity, the action of the automatic brake was defective. In long trains, the presence of a considerable slack motion between cars (which is especially present in freight trains, owing to their looser form of coupling, aggregating from twenty-five to fifty feet in a fifty-car train), also tended to increase the shock of the rear against the front cars (Westinghouse, Rec., p. 118). Hence, the difficulty was a double one. Train-weight and train-length both conspired to prevent a successful solution. And it was to effect such solution that a new structure and method of applying full and quick pressure was invented by Mr. Westinghouse, so that the brake, while retaining its former satisfactory work and functions, might also perform, as required, the function of "Quick Action," and this constitutes the distinguishing feature of novelty of the invention here in question.

The DEFECTS of the automatic brake are correctly set forth by the Courts of Appeals in their "statement" (Rec., pp. 872-3).

CAUSES OF THE DEFECTIVE OPERATION OF THE "AUTOMATIC" BRAKE ON LONG TRAINS.

We next inquire *why* the "automatic" brake was defective in quickness of action.

The quickness of action of a brake depends (*a*) upon the speed with which the compressed air flows or forces itself into the brake cylinder, and in so doing forces the piston home and puts the brake on, and (*b*) also upon the speed with which the braking action is transmitted from car to car.

The speed with which compressed air will force itself into the brake cylinder obviously depends, other things being equal, upon the size of the opening through which the air can rush in.

It was not found practical, however, to admit air *rapidly*, nor through a *large* aperture, *when* such air pressure was taken solely from the *auxiliary reservoir*. This fact is not denied.

There were, Mr. Westinghouse says,

"constructive reasons to limit the size of the passages in the triple valve making communication between the *auxiliary reservoir* and the brake cylinders, and for this reason a period of about three seconds was required to obtain the maximum brake force, from the time that the triple-valve mechanism commenced to admit it from the auxiliary reservoir to the brake cylinder" (Westinghouse, Rec., p. 121, fol. 182).*

* The explanation of constructive reason for a *small* opening where auxiliary-reservoir pressure only was utilized is explained in the record at some length (Record, pp. 317-320), and the fact is undisputed. Another reason is, however, understood to be as follows:

It is well known in mechanics that a large valve, governing a large opening, is not so sensitive or delicate in its operation or movements as one which controls a small opening. Now, a small opening from the auxiliary reservoir to brake cylinder was needed for the comparatively sensitive operation, which was availed of day by day and hour by hour, and perhaps every few minutes, in the ordinary running of trains, in making frequent stops, or in going over different grades, or slowing up at crossings. A large opening from auxiliary reservoir to brake cylinder, by which very quick action alone could be attained, seemed inconsistent with the sensitiveness required for everyday use: and, as very quick action was only required in emergencies, and as emergencies were not happening every day, it did not seem possible to sacrifice the conditions necessary for the proper operation of the train day by day, for the sake of greater efficiency on rare occasions.

But, in addition to quickness of application of full brake force on individual cars, there was a requirement for quick *serial* application of the brakes on one car after another. The nearer the approach to simultaneousness in action throughout the train the better. Approach to simultaneous action, depends upon the speed with which an operative change of air pressure can be made to manifest itself on *successive* cars.

The "plain" or "straight" air brake had been slow, because the operative increase of pressure was large in amount, and had to be transmitted all the way from the locomotive to the rear car of the train, and operated on the cars successively one after another, the transmission of the pressure being, of course, delayed by the friction of the air in passing through the pipes.

The "automatic" brake, as we have already seen, improved upon this method of operation, by storing the pressure, which was to apply the brakes, in an auxiliary reservoir under each car, where it was near at hand and close to the brake cylinder to be operated by it. But it was still necessary, with the "automatic" brake, that an operative change of pressure, by reduction, should be transmitted all the way from the locomotive to the brake to be applied. True, in the case of the "automatic" brake, the change of pressure was by diminution, instead of increase, and the diminution in pressure, which was necessary to cause the triple valve to shift and open the passage from auxiliary reservoir to brake cylinder, was *much less* than the increase involved in the use of the "plain" or "straight" brake; but the *distance* at which the change in pressure was to be felt was still a factor which tended to produce a certain slowness of action, because the reduction took place first at the locomotive, and its effect had to be transmitted backward through the whole train.

What, therefore, was needed for the purpose of quickening the *successive* action of the brakes, when *very quick* action was imperative, was some device, subject to control by the engineer as to its use or non-use, by which, on the occasions when it was urgently needed, and *not* at any other time, (1st) a *larger* discharge of com-

pressed air into the brake cylinder could be had; and (2d), the necessary *escape* of air, adequate to shift each triple valve successively, should take place at or near such triple valve, without requiring the escaping air to travel all the way back to the locomotive (Westinghouse, Rec., 121-2).

THE "QUICK-ACTION" BRAKE.

Mr. Westinghouse took a fundamental step in remedying the defects of prior brakes, by the so-called "quick-action" brake, which is in controversy in the present litigation.

He perceived that what was necessary was to quicken the action of the brakes, *both* on each *individual* car, and *from car to car*; and the simple but beautiful expedient upon which he hit was that of modifying the old "automatic" brake so that, while it retained all its original functions for ordinary use, it should also have the capacity, under the control of the engineer, by which, when an emergency happened and great quickness of action was required, a passage should be opened directly from the *train pipe* (filled by the main reservoir on the engine) to the brake cylinder, and through which the *train-pipe* air *in bulk* could pour into that cylinder.

This discharge of the TRAIN PIPE into the brake cylinder to produce QUICK ACTION was absolutely new with him.

This operation resulted in charging or filling the brake cylinder, and applying the brakes, more quickly than before, and, also, by reason of the fact that the filling of the brake cylinder with air from the train pipe on one car, made what was in effect a *local* vent for release of pressure sufficient to operate the valve on the next car behind, each successive valve acted more quickly than when the diminution of pressure was caused by escape of air *only* at the engineer's valve on the locomotive.

The Circuit Court of Appeals, in the opinion under review, said (R., pp. 876-7) :

"It is not for us to describe how the introduction of train-pipe air into the brake cylinder of each car quickens the action of the brakes, which are already subject to the action of air from the auxiliary reservoir. It is sufficient to say that the engineer, by means of his

valve on the engine and by means of the branch pipe leading from the train pipe to the triple valve of each car, can, by the improvements in controversy, vent the air of the train pipe directly and more promptly into the brake cylinder, and thus more quickly apply the brakes, than he can by the indirect conduit opened by the main valve of 220,556 into the brake cylinder from the auxiliary reservoir when its position is in extreme traverse, as heretofore described. Quick action being the desideratum, the engineer effects it more promptly by the direct means than by the indirect."

Broadly speaking, therefore, Westinghouse's invention of the so-called "quick-action" valve for long trains, consisted of a provision for the admission or charge of air, at the will of the engineer, *direct from the train pipe* (instead of from the auxiliary reservoir alone) into the brake cylinder. This direct access of AIR FROM THE TRAIN PIPE *permitted the use of a comparatively large opening for that purpose*, without impairing the sensitiveness of the ordinary admissions of air from the auxiliary reservoir, and resulted in not only quickening the application of the brake on each car individually, but also resulted in quickening the rate of successive application from car to car, by providing at each car a local vent for the air, sufficient to move the triple valve of the car next behind it (Rec., p. 122, fol. 184 *et seq.*)*

We next turn to see how this invention was embodied in practice in a given structure.

The Patent in Suit.

The invention of George Westinghouse, Jr., above outlined, is described and claimed in his Patent No. 360,070, dated March 29th, 1887 (Record, pp. 782-789).

The specification contains the following brief and clear statement of the objects and *essential features* of the invention, in the following words (782) :

* It is true that the feature of local venting, in order to quicken serial action, had been *attempted* in an earlier patent of Mr. Westinghouse (No. 217,838), but *unsuccessfully* ; 1st, because the discharge of locally vented air was to the atmosphere and not into the brake cylinders, and hence the force was wasted, and, 2d, because the local venting took place *at every application*, and *not only* when the engineer so willed (see opinion MORRIS, J., p. 847).

"The object of my invention is to enable the application of brake-shoes to car wheels by fluid pressure to be effected with greater rapidity and effectiveness than heretofore, more particularly in trains of considerable length, as well as to economize compressed air in the operation of braking by utilizing in the brake cylinders the greater portion of the volume of air which in former practice was directly discharged into the atmosphere.

"To this end, my invention, generally stated, *consists* in a novel combination of a brake pipe, an auxiliary reservoir, a brake cylinder, and a 'triple-valve' device governing, *primarily*, communication between the auxiliary reservoir and the brake cylinder, and, *secondarily*, communication *directly from the brake pipe to the brake cylinder.*"

Then follows a description of the Westinghouse "Automatic" Brake and its mode of operation, and following this (p. 83) is a brief statement of the defectiveness of that brake in operation when the application of *full force* is required, viz.:

"Application of the brakes with their full force has heretofore required a discharge of air from the main pipe sufficient to reduce the pressure in said pipe below that remaining in the auxiliary reservoir after the brakes have been fully applied, and it has been found that, while the brakes are sufficiently quick in action on comparatively short trains, their action on long trains of from thirty to fifty cars, which are common in freight service under present practice, is in a measure slow, particularly by reason of the fact that all the air required to be discharged from the main pipe to set the brakes must travel from the rear of the train to a single discharge opening on the engine. This discharge of air at the engine has not only involved a serious loss of time in braking, but also a waste of air. Under my present invention a quicker and more efficient action of the brakes is obtained, and air which has been heretofore wasted in the application of the brakes is almost wholly utilized to act upon the brake pistons."

The inventor then proceeds with a detailed description of the drawings illustrating his invention, or the selected form thereof.

He chooses, for the purpose of illustration, a "triple valve" which (p. 784),

"accords substantially with that set forth in inventor's patent of the United States No. 220,556, granted and issued to me October 14, 1879,"

stating, however, that (p. 784) it is not claimed as of his present invention,

"saving however as to the structural features by which it performs the further function of effecting the direct admission of air

from the main air pipe to the brake cylinder, as presently to be described,"

Further on in the specification (785-6), and after describing all of those structural features which illustrate the triple valve of the patent in suit, as one of the "automatic" variety previously invented by him, he says :

"So far as hereinbefore described, the triple valve accords in all substantial particulars with, and is adapted to operate similarly to, those of my Letters Patent Nos. 168,359, 172,064 and 220,556, and, in order that it may perform the further function requisite in the practice of my present invention, it is provided with certain additional members, which will now be described."

What now are the *essential* "additional members"?

The patentee proceeds to explain the modifications of the described form of "triple valve," which are necessary to adapt it to "the purpose of effecting the admission of air directly from the "main air pipe 2 to the brake cylinder 7, when it is desired to apply "the brakes with great rapidity and full force."

These "structural features" or "additional members" consist, *essentially*, of, FIRST, a passageway through which air can be admitted *direct, from the main air (or train) pipe to the brake cylinder*, without passing through the auxiliary reservoir, and, SECOND, such a valve arrangement, in connection with such passage, that, when the triple-valve piston makes a short or preliminary movement, the passageway direct from the train pipe to brake cylinder, controlled by said valve, will *not* be opened, while, in the event of a long or full movement of the piston, or "further traverse," as it is called, such direct passageway *will be thrown wide open to the admission of train-pipe air*, and the brake cylinder will be rapidly filled thereby.

The drawings of the patent (Fig. 2) (Rec., p. 783) are rather small, and somewhat encumbered by the numerous figures of reference, so the enlarged drawings introduced into the record, preceding page 469 (original pages 741 and 742), and whose accuracy is undisputed, are here introduced. The principal parts are colored, so as to be easily distinguished.

These drawings showing the patented valve (in the form selected for illustration) in three positions, viz. : Drawing 13, in "Release" position, or "Brakes off;" Drawing 14, in "Service application"

Auxiliary Reservoir.

Auxiliary Reservoir

Drake C.

position, or brakes applied by auxiliary reservoir pressure, and Drawings 15 and 16, "*quick-action*" position.

The patent speaks of these last two operations as follows (p. 787) :

"The admission of air to the brake cylinder through the passage 31" (*i. e.*, from the auxiliary reservoir), "which is opened just before the piston stem comes in contact with the graduating stem, and which corresponds to the feed passage heretofore employed, suffices for the ordinary requirements of braking in regular service. In the event, however, of its becoming necessary to apply the brakes with great rapidity and with their greatest available force, the engineer, by means of the valve at his command" (*viz.*, the engineer's valve on the locomotive), "instantly discharges sufficient air from the front end of the main air pipe to effect a sudden reduction of pressure of about twenty pounds per square inch therein, whereupon the piston 12 of the triple valve is forced to the extreme limit of its stroke in the direction of the drain cup 19, carrying with it the stem 36 and auxiliary slide valve 41, which instantly uncovers the port 42 and discharges air from the main air pipe through the opening of the check valve 49 and the passages 46 and 48 to the brake cylinder, and, each car being provided with one of these devices, it will be seen that they are successively moved with great rapidity, there being practically, on a train of fifty cars, fifty openings for discharging compressed air from the main pipe, instead of the single opening heretofore commonly used. Not only is there a passage of considerable size opened from the brake pipe on each car, whereby the pressure is more quickly reduced, but the air so discharged is utilized in the performance of preliminary work, it being found in practice that the air so taken from the pipe will exert a pressure of about twenty-five pounds in the brake cylinders."

The operations described in the above paragraph will, we think, be made more clear by the drawings opposite the next page—Diagram 10.

In these simpler drawings, all details of construction, and all figures of reference, not necessary for a clear understanding of the structure, are omitted, and the essential parts are colored, so that their changes of position in the different stages of action can be easily followed.

The access of train-pipe air is shown located at the right end of the structure, instead of the left (as in the patent drawings), simply for greater clearness.

The "main valve" of the triple is *black*. Its office is to admit auxiliary reservoir air to brake cylinder.

The "quick-action" valve is colored *red*. Its office is to admit *train-pipe air* to brake cylinder.

The release port is colored *green*. Its office is to discharge air from brake cylinder, in releasing the brakes.

The flow or movement of air, in the several positions of the structure, is also shown by colored lines and arrows, viz.:

Air released from brake cylinder to open air by *green* arrow.

Air flowing from auxiliary reservoir to brake cylinder, in "service" application of the brakes, by *red* line. And air flowing from train pipe to brake cylinder in "quick-action" application by *blue* line.

As will be seen from the above description and drawings, in order to make possible either action or *non-action* of the emergency features, *at the will of the engineer*, Mr. Westinghouse *availed himself of the capacity of the triple-valve piston for varying lengths of travel*.

This double movement was not in itself new, but in his new combination he enabled it to perform a new function.* He provided that the triple-valve piston, when operated by only a *slow or moderate* reduction of pressure, and when making only a *short* or "preliminary traverse," shall open and close the passageways, corresponding to Nos. 1, 2 and 3 in Sketches Nos. 90 and 91, by which the "auxiliary" reservoir was opened to, or cut off from, the brake cylinder; but, when moved by a *sudden or large* reduction of pressure, and given a *longer* or "further traverse," when and only when an alarming danger is near, it shall then *open a passage directly from the train pipe*, and thereby charge *train-pipe air directly into the brake cylinder*.

This gives what is known in this case as "Quick Action."

When only the regular service work of the brake is required, the engineer accomplishes this by a moderate or slow reduction of press-

* The Court of Appeals attributed to Judge MORRIS, in the Circuit Court, the error of supposing that the double traverse of a triple-valve piston was in itself new.

In this they were themselves in error. What Judge MORRIS said was (Rec., p. 846): "It is shown that Westinghouse was the first to use a further traverse of the triple-valve piston to perform the operation required to vent the train pipe into the brake cylinder" (see, also, p. 847).

sure—say two, three or five pounds. This will cause the triple-valve piston to move through its “ preliminary ” traverse, and does all the work required in the normal running of even a fifty-car train.

But when serious danger impends, the engineer makes a sudden or considerable reduction of pressure—say fifteen or twenty pounds, more or less—and then the triple-valve piston makes a longer movement or “ further traverse,” and comes back with such force as to compress spring 39 and push valve 41 off its seat. The *direct access from train pipe* to brake cylinder is then open. Air rushes quickly and *in bulk*, as it were, from the train pipe to each brake cylinder, with the result : *

FIRST. Of charging the brake cylinders with air pressure taken direct from the train pipe, increasing the efficiency of the brake by fully *twenty* per cent., by increasing its quickness in reaching full pressure (Rec., p. 124, fol. 186).

SECOND. That, by making a *new vent* at the triple valve of the *first* car, the reduction of train-pipe pressure at the triple valve of the *next* car is hastened, and the action of *its* triple valve is speeded. This second vent on the *second* car hastens, in like manner, the action of the triple valve on the *third* car, and so on from car to car throughout the train. In this way, the average time of transmitting the braking force and getting the brake shoes into actual engagement with the wheels on a fifty-car train was at first reduced from twelve to *six* seconds (Rec., p. 125), and was finally reduced to *two* seconds, or to the *one twenty-fifth* part of a second per car (Record, p. 134, fol. 201).

THIRD. This increased celerity in action and in power of application are placed *under the absolute control of the engineer*, by being so incorporated into the structure of the automatic brake that the latter retains *for service use* all the essential qualities and functions which especially fit it therefor, but has the superadded function of admitting train-pipe air *for emergency use*, by the opening of a direct

* See, for a further explanation of diagram 10, pages 54, 55 of this brief.

passage therefrom, *when* the piston makes its longer movement or "traverse."

These are the three things which, from a practical standpoint, make the Westinghouse "quick-action" brake, and these are the three points around which are centred substantially all the matters involved in the present controversy.

The specification, before making the claims, contains a generic clause, showing clearly that, within the contemplation of the inventor, the invention which he had made was not one which was confined to or limited by the special construction of the special triple valve which he had selected for the purposes of illustration. He says (p. 788) :

"In using the terms 'triple valve' and 'triple-valve device' I refer to a valve device, however specifically constructed, having a connection with the main air or brake pipe, another with an auxiliary reservoir or chamber for the storage of power and another with a brake cylinder or its equivalent for the utilization of the stored power and with a release or discharge passage for releasing the operative power from the brake cylinder, whether the valves governing these passages or connections are arranged in one or more series and are moved by a piston or its equivalent or by cases of pistons or their equivalents, there being numerous examples in the art of constructions, varying materially in appearance, whereby these functions are performed, both in plenum and vacuum brake mechanisms."

The inventor then states that his invention may be utilized in brakes which work by atmospheric pressure as well as those working by air under artificial compression, but he disclaims a construction of brake mechanism in which a passage from the main air pipe is *always* open, as this, he says, "involves an operation different from that of my invention." He then proceeds with his claims (p. 788), of which the 1st, 2d and 4th are as follows :

"1. In a brake mechanism the combination of a main air pipe, an auxiliary reservoir, a brake cylinder, a triple valve and an auxiliary valve device, actuated by the piston of the triple valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air pipe to the brake cylinder, substantially as set forth.

"2. In a brake mechanism the combination of a main-air pipe, an auxiliary reservoir, a brake cylinder and a triple valve having a piston whose preliminary traverse admits air from the auxiliary

reservoir to the brake cylinder, and which, by a further traverse, admits air directly from the main air pipe to the brake cylinder, substantially as set forth.

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake cylinder and to the atmosphere respectively, and an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake cylinder respectively, substantially as set forth."

Nothing, as it seems to us, can be clearer than the scope of this invention and the meaning of the claims.

The inventor does not assert that he is, in the present specification, describing for the first time an air brake, nor an "Automatic" air brake; nor an air brake which may admit varying amounts of air from *auxiliary reservoir*, according to the varying movements of the triple-valve piston; nor a triple valve the length of whose piston movement could be varied.

All these things were old, and had been previously described or patented by himself.

What had *not* been done was to obtain "*quick action*" by the direct admission of *train-pipe air*.

He *now* asserts that he has produced, and described and illustrated in *one* form,

"A novel combination of a brake pipe, an auxiliary reservoir, a brake cylinder and a 'triple-valve' device governing, primarily, communication between the auxiliary reservoir and the brake cylinder, and, *secondarily*, communication directly from the brake pipe to the brake cylinder."

The preamble to the claims states in distinct terms that his invention is not embodied in a device in which train-pipe air is *always open* to the brake cylinder, and in which communication from the train pipe to the brake cylinder is simultaneously and *always opened* when the piston of the triple valve moves to open communication from the auxiliary reservoir.

The gist of the invention, and the vital point of its novelty, as contained in the preliminary statement of that in which it "consists," is that, in a combination of brake pipe, auxiliary reservoir, brake

cylinder and "a (*not* "the") triple-valve device," such triple-valve device shall "*govern*" primarily (that is, by its primary movement) communication from the auxiliary reservoir to the brake cylinder; and, secondarily (that is, by a secondary movement), communication direct from the brake pipe to the brake cylinder.

There is no mistaking the meaning of those words.

Taken in connection with the statement preceding the claims, in which the inventor expressly states that his invention is not limited in its application to the special form of "triple-valve" illustrated by him, but may be embodied in any "triple-valve devices," whether contained in one or several cases, or worked by one or several pistons, it is clear that the invention is not limited to any particular form or location of the new communication direct from train or brake-pipe to brake cylinder, nor to any particular form of valve for uncovering such direct passageway, when the direct admission of train-pipe air is to be effected.

True, in the illustrative form portrayed in the drawings, the direct passageway from train-pipe to brake cylinder is shown in the *outside* of the casing of the ordinary form of "triple-valve" illustrated, and the valve which closes and uncloses that passageway is outside of the ordinary triple-valve chamber, and is *pushed* off its seat, when required, by a supplemental stem, attached to the front of the triple-valve piston.

But, clearly, these details are not of the *essence* of the invention.

The essence "consists" in the fact that the triple-valve device, however it may be varied in form, and while retaining its well-known characteristics, shall "govern" (*i. e.*, control, at the will of the engineer, by some suitable form of connection), primarily, the port for discharge of air from the auxiliary reservoir to brake cylinder, and, secondarily, the port for discharge of air from the train-pipe to the brake-cylinder.

That the invention may be embodied in a variety of forms, without losing its essential character or necessary elements, will, we think, be evident from a few illustrations.

Two of these are shown in the opposite illustrative diagrams, Nos. 2 and 3, which are not in the record, but which serve to explain our position.

Diagram 2 shows a form in which the passage from the train-pipe to brake-cylinder is at the opposite end of the triple-valve device, but this clearly embodies the same invention.

So, again, the form of valve may be changed from a slide valve to a poppet and the invention will be clearly used, as shown in the next following figure (Diagram 3).

The picture of the valve of the New York Air Brake Co., shown in the opinion of the Circuit Court of Appeals (Rec., p. 883), is a still less closely related form, but was, apparently, conceded by the opinion below to embody the same invention, although the emergency valve was very differently located and was operated by air pressure only, made effective by the "further traverse" of the triple-valve piston.

Clearly, therefore, this invention is one which is not to be too closely tied to particular mechanical forms. It may be embodied, as expressly stated, in a great variety of forms. Its essential characteristics are, however, clearly stated, and the skill of the mechanic art is adequate to express the invention in a great variety of ways.

Doubtless, subordinate invention may be exercised in devising details of arrangement of passages, shape and location of valves, to promote compactness and convenience of the structure; but whenever the essential structural characteristics of the invention above described are found embodied in an "automatic" brake mechanism, whose triple valve "primarily controls the passage from auxiliary reservoir to brake cylinder, and, secondarily, controls the direct passage from train or brake-pipe to brake cylinder," there the invention of Westinghouse is found, and that invention cannot be obscured, nor the claims of the patent (if they be properly expressed) evaded by the ingenuity with which the respective "communications" or passages may be disguised, or the form and location of the valves which control them be modified.

This new invention of Westinghouse is expressed in and covered by the claims.

The second claim perhaps defines it more nearly in the language of the preamble of the patent than any other.

That second claim is in the following words :

"2. In a brake mechanism the combination of a main air-pipe, an auxiliary reservoir, a brake cylinder and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake cylinder, and which by a further traverse admits air directly from the main air pipe to the brake cylinder, substantially as set forth."

Obviously, that claim is not to be limited to the special passages or the special shape of valves chosen for illustration, nor to the pushing of the valve from its seat by an additional "piston-stem." If any brake mechanism, which is to be compared with that claim, contains the combination of a main air-pipe, an auxiliary reservoir, a brake cylinder and a "triple valve" having a piston; and if there be in the structure passages or "communications," *both* for admitting air from the auxiliary reservoir to the brake cylinder and *also* for admitting *train-pipe* air direct to the brake cylinder; and if the structure be such that the preliminary movement of the triple-valve piston (by acting through some suitable or well-known instrumentality) uncovers a communication or passage which only admits auxiliary reservoir air, while the secondary, or "further traverse" (in like manner) uncovers a passage which admits *train-pipe* air, then the essential "structural features" of that claim are present, and the invention of Westinghouse, as defined in the second claim, with all its great advantages, is found, irrespective of the special mechanical connections between the "triple valve" piston and the operating parts or valves, or of the character of those valves, or of the *particular* shape or *exact location* of the "communications" which are opened.

The first claim also states the invention of Westinghouse from another point of view, and defines a special embodiment of it. It is in the following words :

"In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake cylinder, a triple-valve, and an auxiliary-valve device, actuated by the piston of the triple-valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake cylinder, substantially as set forth."

Here, the statement of the new invention is not defined by the requirement that the piston of the "triple valve" should have a "preliminary," and also a "further" traverse, or that the "preliminary traverse" shall govern one passageway, and the further traverse shall govern another.

The inventor is mindful of the fact stated in the preamble of his claims, that the "triple valve," properly so-called, may consist, not solely of a structure containing a *single* piston with *double traverse*, but may consist of a structure having a *series of pistons*, as well as a structure having a *single piston*.

He, therefore, here states his invention in terms which are applicable to either or both of such forms of structure, and defines his invention as one in which, in addition to a valve which admits air from the auxiliary reservoir to the brake cylinder (which is a function commonly performed in the older structures by what is known as the "main" valve of the triple), there shall be an "auxiliary valve" device, actuated by a triple-valve piston, *which shall admit air directly from the main air or brake pipe to the brake cylinder*.

In this claim, the feature of the invention, which is specifically pointed out and made the subject of the claim, is the fact that the direct admission of train-pipe air is effected by a valve "auxiliary" to that which is *primarily* relied upon to admit auxiliary reservoir air (called the "main valve").

In this claim the double traverse of a single piston is not required. It contemplates the possible utilization of *two* pistons, as stated in the preamble to the claims.

In the second claim, on the contrary, the inventor perhaps contemplated the possibility of the separate passages or communications from auxiliary reservoir to brake pipe being closed by a single physical valve-structure, although the opening of the two separate

communications was to be governed, one, by a "preliminary," and the other by a secondary or "further" traverse of the triple-valve piston.

Both claims together seem to adequately protect the invention of Westinghouse, so far at least as the present litigation is concerned.

Each points out *certain essential* features which were new with Westinghouse, and some or all of which were necessary for the production of his new result.

The fourth claim follows the line of the first claim with greater detail and particularity of description, and needs no further special attention, except to again recite its terms, which are as follows:

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake cylinder and to the atmosphere, respectively, and an auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake cylinder, respectively, substantially as set forth."

The invention of Westinghouse, of the quick-action brake, is a "pioneer" invention, or one fundamental in character.

This point is so fully admitted in the opinion of the Circuit Court of Appeals, which is now before this Court for review, that lengthened discussion is unnecessary.

The Court of Appeals, while considering what is regarded as "fatally defective" *language* of the second claim of the patent in suit, yet conceded, in express terms, the commanding value and primary importance of the invention itself. It said (Record, p. 880):

"That this invention of Westinghouse, thus undefined, is one of the highest value to the public, and that it is a pioneer one in the art of quick-action brakes is not denied, and is conceded.

"It is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal protection from the Court in construing the claim."

These words involve none too high praise of the invention of

Westinghouse, which is admitted to be first disclosed in the patent in suit.

An invention which resulted in placing it within the power of an engineer, running a train of 50 cars, to stop such a train in about half the time and half the distance (Rec., p. 127-8) within which any similar train had been previously stopped, is deserving of the public gratitude.

When it is considered that freight trains of such length have become the ordinary methods of transportation, and that, upon their safe running, hundreds, if not thousands, of millions of dollars' worth of property, and tens of thousands of valuable lives, are dependent, the inventor who has contributed in any marked degree to the protection of such lives and the preservation of such property, is entitled to all of the consideration, by way of a fair, and even liberal, construction of his claims, which Courts are able to accord to him, within the established rules of law.

As was said by the late Mr. Justice BLATCHFORD, sitting at Circuit in another case (*Poillon vs. Schmidt*, 6 Blatch., p. 303) :

"The invention as set forth in the Specification is a highly meritorious and useful one, and one which the Court will desire to sustain if consistent with the principles of law."

Judge MORRIS, in the present case, at Circuit (Record, p. 845), used the following language in regard to this invention :

"Now, although quick action emergency brakes were being sought for, no one before Westinghouse had accomplished this result, and the means by which he accomplished it were entirely novel. Indeed, upon first impression it is paradoxical and startling to find that, when a sudden, quick and powerful action of brakes is needed in the face of impending danger, it is to be obtained by a sudden large release of pressure in the train pipe, to the extent of 15 or 20 pounds below that in the auxiliary reservoir, and that by using this low pressure air to operate the brake cylinder, instead of the air under greater pressure stored up in the auxiliary reservoir, this remarkably effective application of the brakes is obtained. In the domain of quick action brakes this device would seem to belong to that class of pioneer inventions the patents for which are to be construed so as to be coextensive with the real invention, if the language of the claim will permit it."

The Circuit Court for the Southern District of New York (LACOMBE, J.), in *Westinghouse vs. New York Air Brake Co.*,

65 F. R., 99, in considering *both* inventions of Westinghouse relating to the quick action brake, viz., the one now before the Court, of Patent No. 360,070, and the later improvement of Patent No. 376,837, said, as follows, and in saying this, he was referring to the opinion of the Court of Appeals, Second Circuit, 63 F. R., 962:

"In those opinions it is held that the two patents 360,070 and 376,837 disclosed, the one the emergency valve, the other the supplemental piston or special motor, which, so far as the art has now progressed, appear to be both essential to the structure of a successful quick-action brake. Both of these inventions achieved great necessities and overcame great hindrances; each is an indispensable part of the 'bridge which carried railroad-car builders from failure to success;' both were products of the inventive genius of the same man; nothing anticipating either is shown."

* * * * *

"Although 360,070 was not declared upon in the earlier suit, it was discussed at great length, and its meritoriousness was clearly recognized. The statements of the problem to be solved as it stood prior to January, 1888, and of the contribution of 360,070 to that solution, as they are set forth in the opinion above cited, leave no doubt that both the Circuit Court and the Circuit Court of Appeals regarded it as a patent of wide breadth; the only difficulty being to find sufficient standing room within the field it occupied to permit according to 376,837 also the necessary breadth of construction to cover the infringing devices then before the Court, and thus save to a meritorious inventor the fruits of his novel and most useful invention."

Under such circumstances, the utmost liberality may be used in dealing with the construction of the claims, and when, as in this case, the *fundamental means*, to wit, the utilization of train-pipe pressure for the purpose of effectuating the quick-action of the brakes, by admission directly to the brake cylinder, in advance of, or simultaneously with, the admission of auxiliary-reservoir pressure, are under consideration, the Court will not confine the invention with unnecessary rigidity to the particular mechanical instrumentalities by which the admission of this new source of air pressure is obtained.

"Means must necessarily be shown in the Specification, but the identical means, or the special devices, were not, in the language of

Machine Co. vs. Lancaster, 129 U. S., 263, 'necessary constituents' of the invention, either in the specification or in the Claim."

Westinghouse Co. vs. New York Co., 63 F. R., 969.

"If the invention is broad and primary in its character, the range of equivalents will be correspondingly broad, under the liberal construction which Courts give to such inventions."

Miller vs. Eagle Co., 151 U. S., 189.

Even a subsequent, and in some respects less important, invention of Westinghouse embodied in his second "Quick-Action" Brake Patent No. 376,837, was held by the Circuit Court of Appeals for the Second Circuit to entitle the inventor to a wide range of equivalents.

In *Westinghouse Co. vs. New York Co.*, 63 F. R., 969, the Court said :

"The skill and mechanical ingenuity of constructors of locomotives can, as will be seen hereafter, in the examination of other patents and of the infringing devices, arrange different details of mechanical construction by means of pistons, valves, ports and springs, which, adopting the supplemental chamber system first conceived and embodied by the patentee, and a kindred but not precisely the same mechanical method for the movement of the piston, will accomplish the same result. The patentee was a pioneer, in that he designed in No. 376,837 a new way to accomplish a desired result, but upon the same general idea which he had unsuccessfully tried to work out in the earlier patent. His later patent was the bridge, and not a mere step, which carried railroad-car builders from failure to success. It is not important now to determine the grade of its pioneering, and whether it may be classed in the list of those inventions which are of the highest rank; but it was an invention created to achieve great necessities and overcome great hindrances, and was one of wide breadth. A Court will not be justified in adopting 'a narrow or astute construction' which should minimize the character of the invention, leave its real scope open to trespassers, and thus 'be fatal to the grant.'"

This phraseology is even more fully and justly attributable to the invention of the present patent in suit.

The Burlington Trials.

The history of the trials of air brakes which resulted in the patent in suit is fully described in the record (*Westinghouse Record*, pp. 117-131).

ented devices—utility. *But it contained a valuable invention and was afterwards improved in details, when patented in number 376,837, as to become a machine of great value to the public, a supplemental piston being supplied in 376,837.*"

This qualified denial of "utility" is, however, conceded later in the opinion in the following words (Record, p. 880, fol. 1419):

"That this invention of Westinghouse, thus undefined, is one of the *highest value* to the public, and that it is a pioneer one in the art of quick-action brakes, is not denied and is conceded. It is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal construction from the courts in construing the claim."

In *Westinghouse vs. New York Co.* (59 F. R., 581, 612), Judge TOWNSEND, commenting upon the apparatus of this patent, said (p. 591):

"But it also appears that these defects were not occasioned by any inherent defect in the construction of the device shown in Patent No. 360,070, and that, when the necessary parts were afterwards adjusted, and, as testified by Mr. Westinghouse, 'when the passages through the quick-action portion of the triple valve were made sufficiently large,' practically the same results were obtained in train stopping as were subsequently obtained by the kind of valve shown in Patent No. 376,837."

In a subsequent case between the same parties, based upon a new infringement, Judge LACOMBE, in granting the preliminary injunction asked for by the Westinghouse Company, said (*Westinghouse vs. New York Co.*, 65 F. R., pp. 99, 104) (p. 100):

"It is unnecessary to enter into any elaborate statement of the history of the art, and of the impress left upon it by these inventions. That entire subject has been discussed with great care, and set forth at great length in the former opinion of this Court and of the Court of Appeals, delivered in the earlier actions between the same parties (59 Fed., 581; 63 Fed., 962). In those opinions it is held that the Patents 360,070 and 376,837 disclosed, the one the emergency valve, the other the supplemental piston or special motor, which, so far as the art has now progressed, appear to be both essential to the structure of a quick-action brake. Both of these inventions achieved great necessities, and overcame great hindrances; each is an indispensable part of the 'bridge which carried railroad car builders from failure to success'; both were products of the inventive genius of the same man; nothing anticipating either is shown."

This opinion was confirmed by the Circuit Court of Appeals (*New York Co. vs. Westinghouse*, 69 F. R., 715).

That a pioneer invention need not necessarily appear, upon its first trial, in its most perfect form has been distinctly ruled by this Court.

In the *Telephone cases* (126 U. S., p. 535) this Court said :

"The law does not require that a discoverer or inventor, in order to get a patent for a process, must have succeeded in bringing his art to the highest degree of perfection."

In *Mergenthaler Co. vs. Press Co.* (57 F. R., p. 506), the Court said :

"It would certainly be a novel doctrine to deny to an inventor the fruits of a broad invention because the machine which first embodied it was rudimentary in character, and failed to do as good work as improved machines made subsequently. None of the great inventions could survive such a test. Ten years after the invention of Howe, the machine first made by him would hardly have satisfied the least exacting sewing woman. The Dodds and Stevenson locomotive would, only a short time after its construction, have been discarded as behind the age, even by the savages of Tasmania. The telephone of Bell is not the perfected telephone of commerce; the Morse telegraph is to-day looked upon as an interesting antique. And yet, it would be an unheard of proposition to withhold from these illustrious men the credit they deserve because their machines were crude at first and were improved afterwards."

The defendants cannot, therefore, gain anything by commenting upon the defects which manifested themselves in the initial trial of the apparatus of the patent in suit; defects, as is seen, which were shortly remedied by the same inventor, and so promptly and perfectly remedied that at the time the testimony was taken, between 1500 and 1900 of these valves were in actual use (Rec., p. 149, x-Qs. 169, 170).

And the only change required for the purpose was purely a mechanical change—merely the enlargement of a port which was too small (Rec., p. 152, fol. 228).

The decision of Judge MORRIS herein was obviously correct, and, as we submit, should be affirmed. It runs thus (Rec., p. 851):

"It has been urged that the invention disclosed by the patent in suit is not of a meritorious character, because in the form in which it is there embodied, or at least in the first mechanism manufactured by Westinghouse, it failed of success in some essentials, and was immediately improved by Westinghouse in a manner which was the subject of a subsequent patent before it was successful in the use

for which it was intended. The defect developed by experimental test and which Westinghouse in a few months remedied was that the opening uncovered by the auxiliary valve was not sufficiently large to suddenly release the full volume of train-pipe air. This was not a defect inherent in the device (59 Fed. Rep., 581-591).

The Defendants' Valve, Its Structure and Mode of Operation.

We have now considered the Westinghouse invention, its general character and essential features, and the position of Mr. Westinghouse as an inventor.

We are next prepared to consider the defendant's structure.

In this connection, it is fair to observe that the defendants' valve has been patented.

The patents of Boyden relating to his type of valve are found in the record, No. 481,134, dated August 16, 1892 (R., p. 797); No. 481,135, of August 16, 1892 (R., p. 809), and No. 481,136, dated August 16, 1892 (R., p. 817).

All of these patents were granted more than two years and a half after the commencement of this suit; and all of them, except the first, were applied for, more than a year after the commencement of this suit; and the first one, namely, No. 481,134, was applied for on September 30, 1889, and this bill was filed on December 12, 1889.

In each of the patents, Boyden endeavors to distinguish his valve, and its theory of operation, from that described and claimed in the Westinghouse Patent No. 360,070.

What effect of weight should be given to the statements in these patents, and to the fact of their granting—both occurring either in anticipation of, or during the pendency of the suit—is one of the points that we hereafter more fully discuss.

Judge MORRIS, in the Circuit Court, did not consider the grants of patents to Boyden, especially under such circumstances, as of any controlling importance (R., p. 852).

The Court of Appeals, on the contrary, considered the action of the Patent Office as

FOLDOUTS TOO LARGE TO
BE FILMED

"In fact, a ruling that the Boyden device did not infringe Westinghouse's 'quick-action' Patent No. 360,070."

"That ruling takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics" (Record, p. 879).

Here is a wide divergence of view.

There are two forms of the Boyden valve before the Court. One is the form described and illustrated in the Boyden Company's catalogue of 1889 (see Diagram opposite p. 44 of Record).

This form is substantially that illustrated in the Boyden Patent No. 481,134.

The second form of Boyden valve is that illustrated in the Boyden Company's catalogue of 1891 (see Diagram from said Catalogue opposite p. 36, which is here inserted).

This form is substantially that illustrated in the Boyden Patent No. 481,135.

The valve of Boyden Patent No. 481,136 needs no special consideration, as there is no proof, in the present case, that the Boyden Company ever manufactured or sold that form.

The defendants' valves of their 1889 catalogue and of their 1891 catalogue are so similar as not to need much separate discussion. The 1891 form is the latest form and the form most largely sold, and it will, therefore, be principally discussed.

Conclusions arrived at in regard to it will be applicable to the valve of 1889.

Considering, now, the defendants' valve of 1891, what features do we find that it embodies, and what is its mode of operation?

Its construction and mode of operation are fully described by complainant's witness, Mr. Newbury (Record, pp. 29-43).

Such mode of operation may be briefly summarized, as follows:

When the structure is to be prepared for action—that is, when the brakes are in a "release position"—the position is shown in the figured diagram (20) "Release Position" (Rec., p. 36).^{*} In this posi-

^{*}The parts which, we contend, correspond to those of Westinghouse are here similarly colored.

tion, air under pressure, entering from the train-pipe, passes the edge of the triple-valve piston 29, through the small grooves at the lower and upper edges of said piston (or under check valve 26), and passes slowly into and through the passage A to the auxiliary reservoir until said reservoir is filled. The triple-valve mechanism is then in a position to act, when desired, for applying the brakes. The brake-cylinder is exhausted or opened to the atmosphere through the exhaust-passage G.

When the brakes are to be applied gradually or slowly, so as to make a "service" stop, air-pressure in the train-pipe is reduced slightly (say from three to five pounds), and the reduction of pressure on the right side of the piston 29 (such piston being subject to the full pressure of the auxiliary reservoir air on the left side, through a passage A) causes the triple-valve piston 29 to move to an intermediate position shown in diagram (21) "Service Application."

Such preliminary movement or traverse of the piston pulls the parts rigidly attached to said piston towards the right of the figure. One of those parts is the stem slide-valve 18, through which is the aperture, *i, k, j*,

In this position of the stem slide-valve, the opening, *i*, of this passage is upon one side of the part 22, through which the stem has been pulled, and the opposite opening of said passage, *j*, is on the opposite side of said part 22.

Auxiliary reservoir pressure, being operative through the passage A, on the left side of the piston, and through the aperture B, into the chamber C, holds the part 22 in a closed position against its seat, while such auxiliary reservoir air passes through the passage *i, j, k*, and from thence through the passage *h*, to the brake-cylinder.

By this action of the parts, a gradual or "service" application of the brakes, by auxiliary reservoir pressure only, takes place. The part 22 has not moved.

Now, if "quick-action" is required, a different set of operations is involved.

In that case, the travelling-piston 29, instead of only making a "preliminary" traverse to the intermediate position, as shown in

*Auxiliary
Reservoir*

Brake C

*Auxiliary
Reservoir*

(21), makes a full, or "further", traverse to the extreme right hand position, as shown in (22) (facing Rec., p. 37).

This is caused by the sudden lowering of the pressure in the train pipe on the right side of the piston to a considerable extent, say fifteen or twenty pounds.

The effect of this "further traverse" of the piston, acting quickly and with considerable force, as the result of the larger reduction of train-pipe pressure, is that the collar *m* upon the stem 18 pulls the part or valve 22 off its seat and *opens a comparatively large passage to the brake cylinder*, under the valve 22, and around the stem 18. The comparatively small amount of air pressure in the chamber C, being allowed to quickly diffuse itself through the large aperture to the brake cylinder, and being only slowly replenished from the auxiliary reservoir through the restricted aperture B, the result is that the pressure of train-pipe air, through the large passage F, in the centre of the triple-valve piston, throws open widely the large check valve 26, *and train-pipe air rushes directly to the brake cylinder*, through the large passage F, past the check valve 26 into the chamber C, under the valve 22, and thence to the brake-cylinder.

Auxiliary reservoir air also flows in, but much more slowly, owing to the fact that it must pass the restricted passage B, which is large enough to admit an adequate supply for service applications, when only the passage *i j k* is opened, but which is *inadequate* to maintain the pressure of air in the chamber C when the valve 22 is pulled clear away from its seat, by the further or extreme traverse of the piston.

These several operations will, perhaps, be more clearly perceived at a glance by inspection of diagram 14 on opposite page.

In this, all unessential details are omitted, and the valves for release, service and quick-action work are colored green, black and red, respectively, as in the Westinghouse diagram 10 (opposite p. 22).

So far, the experts on both sides agree as to the operation of the defendants' structure.

The defendants' experts, however, insist that there is an additional operation which *may sometimes* take place, which is this :

They say that, while the stem slide valve 18, with its aperture and ports *i, j, k*, is in fact used for graduating stops, or "service" stops, in many (if not in most) cases, yet that it is possible to move the triple-valve piston 29 to its extreme right-hand position *so slowly*, and therefore to open the valve 22 or pull it off its seat *so gradually* that the pressure in the chamber C will be reduced so slightly and slowly that the train-pipe air will not have sufficient preponderance to force or throw open the check valve 26, and hence that no train-pipe air will be admitted directly to the brake cylinder.

In such a case, they say, the brake cylinder will be filled by auxiliary reservoir air only, *even although* the piston 29 makes its further or extreme traverse, and even although the valve 22 is opened thereby.

Theoretically, this is possible, but the complainants prove—and the proof is uncontradicted—that this action can *never take place* until the brake cylinder, and the passages beyond the valve 22, *have been so nearly filled with air pressure* from the auxiliary reservoir *before* the valve 22 is pulled off its seat, that there is no substantial reduction of pressure in the chamber C as the result of opening said valve 22, and *no real use in then opening the valve 22 at all*.

On this point the evidence is decisive (see Newbury, R., p. 169, fol. 256 ; Barnes, R., p. 391 ; Westinghouse, R., p. 293, Qs. 431-435) ; and their statements are in accord with what an intelligent consideration of the operation of the structure shows *must be the case*.

Briefly, the fact is, as more fully demonstrated by Barnes experiments (Rec., p. 391), that in *service use*—that is, *without quick action*—the Boyden valve 22 cannot be opened at all to admit auxiliary reservoir pressure to the brake cylinder, until *after* ninety to ninety-five per cent. of such pressure shall have been charged through the port *i j k* ; and this being done, it *made no practical difference whether valve 22 was open or closed*, pressures being equalized at about ninety-eight per cent.

And this demonstrates that valve 22 does not and cannot perform any material portion of main-valve work—that is, the admission of *auxiliary reservoir* pressure to the brake cylinder. That work is done by the port *i j k*; and the valve 22 is (for all *practical* purposes) solely a “quick-action” valve.

Even Boyden cannot say that, as a fact, the valve 22 can *ever* be lifted from its seat without admitting train-pipe air direct to the brake cylinder, and thereby effecting a quick application of the brakes, except in the case of a *single valve* operating *by itself*, when tested in the defendants’ shops (Boyden, Record, p. 578, x-Q. 214).

And all he is willing to assert is that the valve 22 *may* be lifted for this slow admission of auxiliary reservoir air without causing “quick action” by the admission of train-pipe air, if the operation be performed *by “a careful engineer”* (Boyden, R., p. 579, x-Q. 216).

He goes further. He admits that he cannot say that, even with such an engineer, this manipulation could be effected, except on a comparatively *short* train, with a small and unknown number of cars (perhaps not beyond the tenth car, and certainly not beyond the thirtieth) (Record, Boyden, p. 579, x-Q. 215).

He admits further that the circular of the Boyden Co., issued in 1889, *makes no mention* of any such possible operation, although it *fully describes the others* (Rec., p. 575, x-Q. 199), and he also admits that the engineers’ valve, advertised by that company for use to apply brakes, has no running position which would result in such manipulation (p. 578, x-Qs. 210, 211). The assertion that the valve so operates is thus clearly shown to have been an afterthought.

Inasmuch as “quick action” of brakes, by the admission of train-pipe air direct to the brake cylinders, is particularly useful only on *long* trains of, say, from 30 to 50 cars, and as it is not even pretended that the Boyden valves can be so manipulated as to admit auxiliary reservoir air only, except on trains of 30 cars *or less*, and perhaps not on trains of more than *one* car, that particular juggling with the valve need not, we think, be taken into serious consideration.

The question is: What is the *ordinary operation* of the apparatus, when manipulated and acting in the ordinary manner, and on long trains of from 30 to 50 cars?

If, under such circumstances, the parts operate in a given way it is of little importance what they can be made to do by special manipulations on *short* trains, upon which their peculiar functions are not needed.

The operation of the Boyden valve, therefore, on long trains, and *under all ordinary circumstances of manipulation*, is as follows, and *only* as follows :

For "service" applications, or for graduating the speed of the train, the triple-valve piston 29 makes a preliminary traverse to the right, under the influence of a slight reduction of train-pipe pressure, and in so doing pulls out the stem slide valve 18 (black), so as to uncover its port *i*, opening the passage for auxiliary reservoir air only through port *i*, passage *k* and port *j* to the brake cylinder.

During this operation, the valve 22 (red) is not moved from its seat, and cannot move, because, until the brake cylinder is substantially full, and, therefore, until the brakes are, at least, *nearly fully* applied, the pressure upon its right-hand side, which holds it to its seat, will be greater than that upon its left-hand side, which would tend to force it from its seat.

Now, when "quick action" is required, the operation will be as follows :

A sudden great reduction of pressure in the train pipe on the right-hand side of the piston 29 will cause the said piston to make its complete or further traverse, and, as a result of that traverse, the valve 22 (*red*) will be pulled off its seat by the contact of the collar *m* with its under side. The air in the chamber C being then suddenly allowed to diffuse itself from the chamber C into the large brake cylinder, its *pressure* will be reduced, and the check valve 26 will open by pressure of train-pipe air, and train-pipe air will rush directly past the check valve, past the valve 22 and through the large openings thus formed into the brake cylinder.

The brake cylinder will be much more rapidly filled than when auxiliary-reservoir air *only* is supplied through its restricted passage, and the brakes will be applied with "quick action."

In the Boyden Patents will be found a description which accords with that given above.

Boyden Patent No. 481,135 says (R., p. 809) :

"This invention relates to the construction of valves for automatic air brakes, and has for its object to provide for admitting air-pressure to the brake cylinder from both the train-brake pipe and the auxiliary reservoir, thereby effecting a more powerful and also a quicker application of each brake and at the same time so quickly reducing the air pressure in the train-brake pipe adjacent to the said valves that all the brakes of a train will be applied at nearly the same time."

And, again, on page 812 :

"To apply the brakes by graduation a slight reduction of the pressure in the train pipe moves the piston 29 and its attached parts until the shoulder *q* on the stem 18 comes against the main valve 22 (the main valve remaining immovable on its seat, owing to the air pressure in the valve chamber C, holding it thereon). This movement closes the release valve port *i* and draws the graduating stem 18 through the main valve 22 sufficiently far to expose the graduating port *k*¹ in the valve stem to the air pressure in the valve chamber C. The air then passes from the auxiliary reservoir by way of the large passage A and small passage B into the valve chamber C, and then through the graduating port *k*¹, passage *o*, and opening *k* in the valve stem and the passage *g* to the brake cylinder, where it affects the partial application of the brakes. This operation, which does not open the main valve port, is due to the fact that the restricted communication B, through which the auxiliary reservoir air enters the valve chamber C, is larger than the graduating port *k*¹, and, therefore, the pressure in the valve chamber is kept substantially equal to that in the auxiliary reservoir. This retention of the pressure in the valve chamber when graduating holds the main valve 22 and the check valve 26 seated on their respective ports."

And again (R., p. 813) :

"The brakes may be applied *fully* in two ways : first, by the auxiliary reservoir pressure alone, and, second, by the auxiliary reservoir pressure in conjunction with the train-pipe pressure. The first mode is used when an ordinary gradual stop is required, such as at a station. The second mode is used when an emergency stop is required, such as upon the occurrence of an accident. To apply the brakes fully for an ordinary stop, a limited amount of train-pipe air is continuously discharged from the engineer's valve, which reduces the pressure in the train pipe and slowly moves the piston 29 to the left and opens the main valve 22 sufficient to practically maintain the same air pressure on both sides of the said piston.

The piston and the said valve will be retained in the position just mentioned, or the position will slightly vibrate back and forward, causing the valve 22 to repeatedly unseat and seat by the discharge of the auxiliary reservoir air (through the valve chamber C to the brake cylinder), being about equal to the continuous discharge of air from the train pipe at the engineer's valve. Under these conditions the pressure in the brake cylinder, valve chamber C and auxiliary reservoir will equalize, and thus the ordinary function of the triple valve in applying the brakes fully by the auxiliary reservoir pressure alone is accomplished."

The latter part of this description, as we have already shown, is one of a merely theoretical operation.

The patent then describes its "quick-action" function, as follows (R., p. 814):

"To apply the brakes of a train quickly and with full power for an emergency stop, the engineer's valve will be moved to close communication between the storage tank on the locomotive and train-pipe and open the latter to the atmosphere and effect a sudden reduction of pressure of from ten to twenty pounds in the train-pipe. The effect of this sudden diminution of pressure in the train-pipe is immediately manifested at the triple-valve mechanism on the first car, causing the valve-piston 29 to be moved by the higher pressure of auxiliary reservoir air quickly to its full outward position, thus moving the main valve 22 and opening the main port *c*, so that the air pressure contained in the valve-chamber C may exhaust freely into the brake-cylinder. The supply of air from auxiliary reservoir to the valve-chamber is conducted through the restricted or small passage B. * * * The exhaustion of pressure from the valve-chamber C or the great reduction of pressure therein following the sudden opening of the main port *c* brings said air pressure below that existing in train-pipe, whereupon the check-valve 26 will be immediately unseated by said train-pipe pressure, and train-pipe air will then pass directly into the brake-cylinder J, thus effecting the quick application of the brakes and also further reduction of pressure in the train-pipe that will be sufficient to accelerate the action of the valve mechanism on the cars following."

This patent of Boyden's No. 481,135 (as well as the other patents of Boyden's No. 481,134 and 481,136) seek, it is true, to disguise the really essential facts of the operation of the Boyden valve, and to differentiate its operation from that of the Westinghouse Patent No. 360,070, by including (as above quoted) a description of the intermediate kind of brake application, which the patent calls "full service application," and in which kind of application the

patent asserts that the structure will operate to apply the brakes fully by the *slow opening* of the valve 22, an opening *so* slow that that valve will admit only auxiliary reservoir air.

This alleged intermediate operation of the Boyden valve has, as we have seen, no real foundation in actual use. It is never realized in practice, as expressly proved by a practical engineer, Mr. Kidder, who used the Boyden valves in the practical running of trains (Record, pp. 425-428); also by Mr. Nellis, a practical machinist and locomotive engineer (Rec., 433-435), who took part in the same practical test; and there is not only no proof that it actually took place at all in practical use, but Boyden himself admits that he cannot say that it *could ever* take place in use *on long trains*.

This description of this alleged intermediate and theoretical mode of operation is apparently introduced into the Boyden Patents for the purpose of giving color to the propriety of calling the valve 22 "the main valve" of the triple valve.

Boyden had doubtless noticed that, in the Westinghouse Patent No. 360,070, Westinghouse speaks of the valve 41, which admits train pipe air directly to the brake cylinder, as a valve which is auxiliary to, and independent of, the main valve of the triple valve, and he apparently conceived the idea of *calling* the valve 22 (which certainly does perform the "quick-action" work in his valve), "the main valve," and by assigning to it a function in admitting auxiliary reservoir air to the brake cylinder, in a *possible* service application, he laid a foundation, as he supposed, for *asserting*, in his description, that he has dispensed with an *auxiliary*, or supplementary, valve for doing quick action work, and that he was performing that service by a valve which he *calls* the "*main valve*."

By so doing, he hoped to avoid the phraseology of the Westinghouse claims, and, so, the charge of infringement.

The difficulty with the contention is, that the *real* "main valve" of the Boyden structure, and of his patent, is the *sliding stem valve 18, with its port i, passage k and opening j, through which auxiliary*

reservoir air is admitted for all practical purposes, and under all practical circumstances—especially on long trains.

The “main valve” of a triple valve is the valve which is *relied upon* for the admission of *auxiliary reservoir air* to the brake cylinder in the operation of service braking.

It is that function which the stem slide valve 18 *always* performs in all *long* trains, and *for all practical purposes* even on short trains.

That valve 18, with passages *i, k, j*, is the true “main valve,” and that fact is not to be disguised, because Boyden has incorrectly *called* the valve 22 “the main valve,” when it is *really* the “emergency” valve, and never does operate otherwise on long trains at all; nor upon any trains, except as the result of some careful manipulation, after the brakes have been nearly fully applied, and when there is no use whatever of its operating.

The Defendants' Valve Infringes the 1st, 2d and 4th Claims of the Westinghouse Patent No. 360,070.

If the construction and mode of operation of the “quick-action” valve of the triple valve structure of the Westinghouse Patent No. 360,070, have been clearly explained and fully apprehended, and if the construction and mode of operation of the Boyden valve have also been clearly explained and apprehended, there will then be little difficulty in examining the question of infringement, especially in view of the fact that the invention of Westinghouse is concededly one of a “primary” character, and

“is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal construction from the Courts in considering the claim.”

(Court of Appeals Decision, Record, p. 880.)

We first consider the second claim.

(1) The Second Claim is infringed.

The phraseology is as follows:

“2. In a brake mechanism the combination of a main air pipe, an auxiliary reservoir, a brake cylinder and a triple valve having a

piston whose preliminary traverse admits air from the auxiliary reservoir to the brake cylinder, and which by a further traverse admits air directly from the main air pipe to the brake cylinder, substantially as set forth."

Unless this claim be "fatally defective" (as held by the Court of Appeals, the error of which position we hereafter hope to show), it is clearly applicable to defendants' apparatus.

Defendants' apparatus is admittedly a brake mechanism possessing a double capacity; viz., (1) for service use, and (2) for emergency or "quick action" use.

It contains a combination of a main air (train) pipe, an auxiliary reservoir, a brake cylinder, a triple valve having a piston, and this piston *has*, and is designed to have, a *double traverse*.

Its shorter or "preliminary" traverse operates directly to shift the sliding stem valve 18, with its ports and passages *i j k* (black), so as to admit "auxiliary-reservoir" air *only* to the brake cylinder; and its longer or "further" traverse (when operating by a *sudden* and *comparatively large* reduction of pressure) unquestionably admits air from the main air (train) pipe to the brake cylinder. It does this by pulling the valve 22 (red) off its seat and opening a large passage to the brake cylinder, and by suddenly producing such large differential pressures on the opposite sides of the check valve 26, that it flies open and admits train-pipe air directly to the brake cylinder.

(2) *Even if the defendants' "quick-action" valve has an additional duty, that does not help defendants.*

Suppose it to be true, as alleged by the defendants, that, by *careful* and *slow* manipulation, the piston of the triple valve could be moved so slowly, and by such slight and gradual reductions of pressure, that the valve 22 *may* be pulled off its seat without allowing the introduction of any train-pipe air, or without allowing the opening of the check valve 26 for that purpose, does the capacity for this slow manipulation, by means of a very moderate and gradual reduction of air pressure, change the fact that, *with a quick and large reduction* of pressure, and a complete or "further traverse" of the piston *thereby* produced, the direct admission of train-pipe air

to the brake cylinder, and the resulting "quick action" of the valves, is inevitable?

Does the fact that the defendants have so constructed their valve that it not only performs *all* the operations of the Westinghouse valve, but is, *also*, capable, by very careful manipulation, of partially performing an additional function, make any difference?

We have already shown that this alleged additional function is of no real value. The apparatus cannot be manipulated so as to open the valve 22 to admit auxiliary-reservoir air, *without admitting direct train-pipe air, except after the brake cylinders have been substantially filled with auxiliary-reservoir air, and hence the brakes have already been applied.*

We have also shown that this possible manipulation cannot, in fact, take place in connection with the use of the apparatus on long trains, for which alone the apparatus is expressly designed; and that the alleged additional mode of operation is, therefore, an unimportant and idle one, under the very conditions in which the defendants' structure, as a whole, is designed to be operative and useful.

Admitting then, that, theoretically, the defendants' valve is capable of an *additional* mode of operation to those specifically described and claimed in the Westinghouse Patent in suit, does that relieve the defendants of the charge of infringement?

This has been so frequently denied by recognized text writers, and authoritatively decided to the contrary by courts, that a few references are all that is required to disprove the contention.

"One thing, to be equivalent to another, must perform the same functions as that other. If it performs the same function, *the fact that it also performs another function is immaterial to any question of infringement.*"

Walker on Patents, Sec. 352.

"Again, equivalence is not affected by the fact that the new element performs in the invention some function in addition to the old."

Robinson on Patents, Sec. 251.

"If the question was between a single patented device, conceded to be new, and a device claimed to infringe, because an equivalent, the alleged infringer could not protect himself by showing

that, although his device was an equivalent of the patented device in all its functions, and in its construction and mode of operation, yet, by other or additional features, it possessed other and further useful functions. Such a device would, perhaps, be an improvement upon the patented device, but must be, nevertheless, deemed an appropriation of the former."

Sarven vs. Hall, 9 Blatch., 524-538.

"The only difference worthy of notice is, that its forward edge or side is, in the Clipper, elongated and curved upward, in the more perfect form of a shoe. On that difference I have already observed at some length, and will not here repeat my observations. I may add, however, that it partakes rather of the character of difference in degree than difference in function, although, in the complainant's machine, this function of the device is imperfectly performed, and, in some situations, might not be effective. Besides, this Court, on a former occasion (*Sarven vs. Hall*, 9 Blatchf. C. C. R., 524), held that a device is not less an equivalent of another merely because, superadded to all the functions of such other, it may perform another office. Still less does it fail to be the equivalent of another, because, besides all the functions of such other, it performs some of the offices more effectively or better, so long as it performs them in substantially the same way, and uses substantially the same means."

Wheeler vs. The Clipper Mower and Reaper Company, 10 Blatch., 181-195.

"If not exactly the same thing, in mechanical construction, it is, clearly, a mechanical substitute for it. It may perform some other functions, but this does not prevent it from being an infringement."

Norton et al. vs. California Automatic Can Co. et al., 45 Fed. Rep., 637, 638.

"The mechanism of Gordon is simply reversed in Palm's device. In the former the upper sharpened edges of the cleats on the wedge arms, and the lifting of the casing cause the wedge arms to catch the well wall, and thus secure the starting point in a self-supporting casing, viz., a stationary base; in the latter, the spring and gravity, or jarring, cause the same result, though from an opposite starting point. In both, increased pressure on the wedge cone aids and finishes the work. *That the additional function of the wedge arms helping sustain the casing appears in the Palm device does not make it any less an infringement.* It is still Gordon's device inverted, plus the added function of the sustaining aid of the wedge arms. As such, it is our duty to decree it an infringement." * * *

Musseth vs. Palm, 51 Fed. Rep., 824, 826.

"If the mode of effecting the continued mixture adopted by defendant should be deemed a new and useful improvement, they might perhaps have a patent for that particular device without being entitled to use Tilghman's process, on which it is but an improvement.

* * * * *

"The introduction of an improvement gives no title to use the primary invention upon which the improvement is based."

Tilghman vs. Proctor, 162 U. S., 707.

"If he be the original inventor of the device or machine called the 'divider,' he will have a right to treat as infringers all who make dividers operating on the same principle, and performing the same functions by analogous means or equivalent combinations, *even though the infringing machine may be an improvement of the original, and patentable as such.*"

McCormick vs. Talcott, 20 How., 402.

See, also,

Blake vs. Robertson, 94 U. S., 728-733.

Cochrane vs. Deener, 94 U. S., 780-786, 787.

Marsh vs. Seymour, 97 U. S., 349-359.

(3) *The fact that defendants selected a different form of triple valve, to which to add the "Quick-Action" element, does not help them.*

Nor, again, can the defendant escape the charge of infringement solely because his apparatus is very different in form or appearance from that of Westinghouse?

The contrary of this has been so definitely stated by this Court as to leave nothing further to be advanced on the subject.

In *Machine Co. vs. Murphy* (97 U. S., 120), this Court said:

"Similarities or differences are not to be judged by the names of things, but the machines, or their several devices or elements, must be examined in the light of what they do, or what office or function they perform and how they perform it. One thing is substantially the same as another if it performs substantially the same function or office in the same way to attain the same result; and things are substantially different when they perform different duties or in a different way or produce a different result. For the same reason similarities or differences are not determined by the mere fact that things are apparently the same or are of a different shape or form; but the true test of similarity or difference is the same in regard to shape or form as in regard to names. In both cases regard must be had to the mode of operation or the way in which the parts work, and the result as well as the means by which the result is attained."

Let us apply these principles to a comparison of the Westinghouse structure with that of the defendants.

The illustrated form of the Westinghouse structure is that of a

triple valve of the form shown in the Westinghouse prior Patent No. 220,556, but provided with certain additional structural features which give it the capacity for "quick action."

The defendants' structure is also a triple-valve apparatus, modified by the addition of certain structural features, which confer upon it the same additional function.

Of course, the particular form of the triple, which is used as the basis of "quick-action" modification, is unimportant.

Westinghouse has (as already seen) expressly guarded, in the preamble to his claims (Record, p. 788), against any limitation to his specific form of triple valve upon which his improvements are engrafted.

And, if the Westinghouse Patent had not contained this express statement, the law would imply the same or an equivalent recital.

A few illustrative diagrams will, perhaps, better than mere description by words, illustrate the fact that, for all essential purposes of the Westinghouse invention, the defendants' apparatus is a mere change of form.*

Let us see how this is, by a renewed study of *the exact mode of operation* of the Westinghouse structure :

Opposite the next page is diagram 10 (already used at p. 22), illustrating the particular type of triple valve adapted for "quick action" which is illustrated in the patent in suit, No. 360,070.

Unnecessary parts are omitted, and only those features which are here in controversy are shown.

Colors are used, so as to place clearly before the eye the several parts, so that they may be carried in mind. The different air pressures, and the directions of air pressure, are shown by appropriately colored lines in the different figures. The figures show the several parts of the valve in its three characteristic positions.

* These illustrative diagrams are not a part of the record ; they are simply a means of conveying to the Court our idea of the character of the changes made by defendants, as being simpler and more easily understood than words alone.

The first figure shows the apparatus in the "Release" Position, or "Brakes Off."

The triple-valve piston occupies its extreme left-hand position. The "main valve" (colored black) closes the access from the auxiliary reservoir to brake cylinder, and leaves open (as shown in green) the valve aperture from the brake cylinder to the open air.

The opening from the train pipe is closed by the "quick-action" or *emergency* valve (colored red), and by the check valve located below.

The check valve is kept closed by a spring until the difference in air pressure upon its two sides is sufficient to open the valve against said spring.

As the emergency valve (red) prevents any excessive pressure on top of the check valve in the Release position, the check valve is kept closed.

An interior auxiliary poppet valve of Patent No. 220,556 (colored yellow), to be hereafter explained (pp. 69-78), is closed.

The second Figure, on the same page, illustrates the change of position of some of the parts when the piston takes a "preliminary," or half traverse to the right, under the influence of a small reduction of train-pipe pressure.

Under such circumstances the "main valve" (black) has been shifted so as to bring one of its apertures opposite the port to the brake cylinder.

The poppet valve (yellow) has been also shown pulled to the left. Auxiliary reservoir air (shown by a red line and red arrow) now enters the brake-cylinder, and the brakes are applied by auxiliary-reservoir air only ("Service" or "Graduating" work), through the comparatively small passageways in and controlled by the "main valve."

The shifting of the "main valve" has also closed the exit from the brake cylinder to the atmosphere (colored green), so that the air charged into the brake cylinder cannot escape.

The emergency valve (red) still remains closed. The piston has not traversed sufficiently far to move it. As there is no preponder-

ating difference of pressure on opposite sides of the check-valve, the check-valve also remains closed, and there is no access of train-pipe air to the brake cylinder.

The third figure on the same page, shows the position of the parts when the extreme or "further traverse" of the triple-valve piston takes place, under the sudden and large reduction of train-pipe pressure. In this case, the release-port from the brake cylinder to the atmosphere (green) still remains closed, and the brake cylinders may be filled. The main valve (black) has been shifted further to the right and therefore still admits auxiliary reservoir air (shown by the red line and arrow); *but slowly*, because of the small size of the aperture.

The sudden lowering of the train-pipe pressure, and the quick and extreme or "further traverse" of the piston, have, however, pushed the emergency (red) valve off its seat. *The check valve has now been subjected to a marked difference of pressure on opposite sides.*

The train-pipe pressure, although reduced to 55 pounds from its initial force, is still vastly in excess of the pressure *slowly percolating from the auxiliary-reservoir through its restricted aperture*, and expanding in the large spaces below and beyond the check-valve. Consequently, the check-valve *now opens*, and train-pipe air (shown by the blue line and arrow) rushes directly through the comparatively large passages and apertures to brake cylinder, the brake cylinder is, therefore, *quickly filled* and the brakes are applied, with "quick action." *

* In this, and in all other diagrams, the *red* numerals indicate the differing ("differential") air pressures which exist for a moment ("momentarily"), when the "quick-action" valve is opened, and which differing pressures, then existing on opposite sides of the *check valve*, cause it to open and admit TRAIN PIPE air.

Now, to see what changes may be made in the illustrated form of the Westinghouse apparatus of Patent No. 360,070, let us examine a structure in which one feature, wholly unnecessary for "quick action" (which is the main feature in controversy here) is eliminated.

This feature, which we are now to consider as eliminated, is the supplementary poppet valve (yellow).

That valve is, as will be fully explained, merely a delicate valve for *closing* and *reopening* the aperture through the main valve, *after* the latter has once been moved into a position which permits the brakes to be applied, *without requiring the main valve to again move*.

It performs no function in connection with "quick action," and may, therefore, be left out of account *for the present*.

On the opposite page is shown (diagram 1) a triple-valve contrivance, adapted for *quick action* in the manner described and claimed in Patent No. 360,070, but with this delicate "poppet" valve (yellow) omitted.

It will be immediately perceived that all the essential operative "quick-action" features are present in this modified valve, although the delicate poppet valve (yellow) is omitted.

The first figure represents the parts in the initial or "release" position, with the brakes off. The triple-valve piston is in its extreme left-hand position. The main valve permits the opening (green) from brake cylinder to atmosphere to exist. The access from the auxiliary reservoir to brake cylinder is closed by the "main valve" (black). All access from train pipe to brake cylinder is closed by the emergency valve (red).

The second figure, on the same page, illustrates the position of the parts in "service" work.

The main valve (black) has been shifted to close the aperture (green) from brake cylinder to the air. The restricted aperture from auxiliary reservoir to brake cylinder is opened, and auxiliary reservoir air (red line and red arrow) is filling the brake cylinders. The access from train pipe to brake cylinder is closed by the emergency (red) valve and by the check valve.

1—Release (Brakes Off).

1—Service Application.

1—Quick Action.

The third figure represents the same apparatus in "quick-action" position.

The piston has been shifted to the right, and makes its extreme or "further" traverse. The emergency valve (red) has been pushed off its seat. The *difference of pressure* on opposite sides of the check valve now causes the check valve to open. Train pipe air (indicated by blue line and blue arrow) flows direct to the brake cylinder, and is accompanied by a smaller amount of auxiliary reservoir air (indicated by red line and red arrow).

No one will dispute that the invention of Patent No. 360,070 is clearly illustrated in the apparatus thus shown.

Now, let us proceed a step further.

It is obviously not important that the emergency valve (red) should be located on the *right* side of the piston, or that it should be *pushed* off its seat.

If the mere location of the principal passages be changed, the emergency valve (red) may be located on the *left* side of the piston.

The diagram opposite, marked 2, illustrates these changes in the location of the parts, being otherwise the same as diagram 1.

A few moments' inspection of these figures shows that all of the operative parts are really the same, the change being a mere change of location, without affecting the functions of those parts.

In "2-Release", the parts are in a released position, and both the main valve (black) and the emergency valve (red) are closed.

In figure "2-Service", the piston has taken its "preliminary" traverse. The main valve (black) has been shifted so as to close the release port from brake cylinder to atmosphere (green), and the port from auxiliary reservoir to brake cylinder (red line and red arrow) is being opened.

The emergency valve (red) remains closed.

The third figure shows the "quick action" of the brakes.

The piston has made its extreme traverse. The main valve (black) and the emergency valve (red) have both been *pulled* off their respective ports. Auxiliary-reservoir air (red line and red arrow) enters through its *restricted* aperture slowly. Train-pipe air (blue line and blue arrow) asserts a preponderating pressure on the check valve, which consequently opens, and train-pipe air rushes through the large aperture to the brake cylinder.*

We see by these diagrams that the position of the emergency valve

* All forms of "quick-action" triple valves necessarily involve *some form* of a wall or partition between auxiliary reservoir air and the direct passage for train-pipe air. It will be observed, by inspection of diagram 2, that the change in the location of the "emergency" or "quick-action" valve 41, from the one side of the piston (*opposite* to the side upon which the main valve is situated, as in diagram 1) to the other side of the piston (the *same* side as that of the main valve, as in diagram 2), involves the use of a "partition" (9), and the "restricted" passage for auxiliary-reservoir air must be *through* it or *around* it; otherwise, the continual presence

2-Release (Brakes Off).

2-Service Application.

2-Quick Action.

(red), on one side of the piston or the other, is immaterial to the invention of Patent No. 360,070. The position may be better in one case than in the other or not, but there is no change of function, nor of the way in which the functions are performed. The change involves a mere change in the form and location of the passages and of the valves.

But let us proceed a step further, and consider whether the *form* of the emergency valve (red) itself is material.

In the two prior diagrams, the emergency valve (red) has been shown as a "slide valve."

Is a "slide valve" essential to the contrivance?

Diagram 3, on the opposite page, tends to show that it is not.

In this diagram, the only substantial change that has been made is the change in the emergency valve (red), from a "slide valve" to a "plug" or "poppet" valve. Said valve no longer *slides* from its seat; it is *lifted* from its seat. There has been a change in the arrangement and location of the air passages, caused by the change in the form of valve and the way in which it seats itself, but there is no change of substance.

The parts operate, in all essential particulars, in precisely the same way, as will be evident upon a brief examination of the respective figures; and cause both "service" application and "quick-action" application in the same way as when a "slide" emergency valve is used.

If the changes in form and location of the parts, illustrated in diagrams 1, 2 and 3, are not such as to substantially differentiate the structures therein shown from the Westinghouse invention of Patent No. 360,070, claims 1, 2 and 4 (as we may easily see), then neither (as we shall show) are the changes of form and arrangement embodied in the defendants' valve.

of auxiliary-reservoir air, at higher pressure, in the passage containing the "quick-action" valve, would prevent the flow of train-pipe air into and through this passage when the "quick-action" valve is opened. Boyden's "partition," hereafter considered, is, therefore, a mere incident to the location of the "emergency" valve in his structure, viz., upon the opposite side of the piston from that of the Westinghouse. The partition is numbered 9, wherever it appears in this form.

In considering the question of infringement, especially in connection with the first and fourth claims, let us consider the contention of the defendant, that all that they have done is to adapt an old form of triple valve to quick-action work, *without providing* it with any auxiliary "quick-action" valve.

Bear in mind, still, that the Westinghouse Patent is not limited to a particular form of triple-valve structure.

The quick-action invention may, as he contends, be engrafted upon, or caused to be embodied in, *any* of the various known forms of triple-valve structures.

Now, the defendants contend that what they started with, when Boyden proposed to modify a triple-valve structure so as to make it capable of "quick action," was an old form of "triple," and one devised by Westinghouse himself.

The Westinghouse Patent No. 141,685, dated August 12, 1873, is concededly the *form* of triple valve upon which Boyden worked, in constructing the valve complained of.

See Church's evidence, Record, pp. 623, 624.

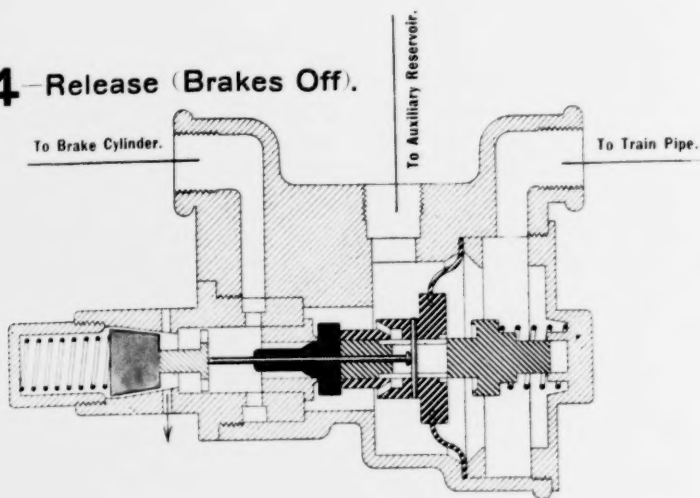

What Boyden really did, as we now hope to show, was to modify the structure of Patent No. 141,685 (1st) by altering the "main valve" of Patent No. 141,685 in shape; (2d) by providing an "additional valve," which should act to admit train-pipe air direct to the brake cylinder; (3d) by changing the location and direction of the air passages so as to admit train-pipe air.

That this was the real character of the changes will, we think, be apparent from an inspection of the following diagrams, in which each of these changes are shown as separately introduced, so that their real character will be better understood.*

The Boyden valve in controversy is represented by diagram 14, opposite page 41, and this diagram represents the three characteristic positions of the parts of the valve, viz., the "release" or "brakes-off" position, the "service" position (for ad-

* It is to be understood, of course, that these diagrams, also, are not a part of the record, but are illustrations which perhaps more easily convey to the mind a realization of what the defendants really did than would a description in mere words.

4—Release (Brakes Off).

4—Service Application.

6—Release (Brakes Off).

6—Service Application.

mitting auxiliary reservoir air), and the "quick-action" position (for admitting, also, direct train-pipe air).

In diagram 4, opposite the preceding page, will be found the plain triple-valve of Patent No. 141,685 (with unnecessary details omitted).

As this valve was capable of admitting only auxiliary reservoir air to the brake cylinders, two positions only are shown, viz., 4—"release" position and 4—"service application" position, in which auxiliary reservoir air is admitted either partially and gradually, or fully, according to the extent to, and length of time during, which the "main valve" (black) is pulled off its seat.

Starting with these figures, illustrating the valve of Patent No. 141,685, the *real* nature of the changes that Boyden has made, to convert this valve into a "quick-action" valve, will be easily comprehended, if they be considered one by one.*

These changes may be enumerated as follows :

FIRST. The defendants have changed the form of the "main valve" (black) from a "plug" form of valve to that of a "stem slide valve." This change is illustrated in diagram 6, on the opposite page, which shows two positions of the valve of Patent 141,685,¹ modified merely by altering the "plug" form of "main valve" into a "sliding stem valve" and changing the ports in it,

* It is to be noted, in passing, that Patent No. 141,685 shows that it was not a new expedient of Boyden's to cause the *release* of air from the brake cylinder to the atmosphere to be effected by a valve (green) *separate* from the "main-valve" (black).

In some of the old forms of Westinghouse triple, as, for instance, in the form shown in Patent No. 220,556, and in the form shown in Patent No. 168,359 or 172,064, the "main-valve," itself, is provided with an aperture which enables it to do the work of "releasing;" but in the earlier patent of Westinghouse, No. 141,685, the release-valve (green) is separate from the "main-valve" (black), and is located at the left side of the structure.

This is the position and arrangement of the parts embodied in the defendants' valve, and is adverted to simply to show that the change of position of the "release" valve is not one which affects the present controversy.

A similar change of position of the "release" valve used in connection with the "quick-action" valve of Patent No. 360,070 (the patent in suit), without any change of function, is illustrated in diagram 12, opposite, behind diagram 6.

for the admission of auxiliary reservoir air to brake cylinder, so that they become operative by being drawn out of the bushing or casing which surrounds said "main valve" (black).

If the aperture through the valve be *partly* uncovered, there will be a *partial* admission of air, just as when the plug main-valve of diagram 4 is only slightly lifted.

It is clear that, so far, there has been no *substantial* change from the structure of Patent No. 141,685. It does exactly what it did before, but does it by means of the movement of stem "slide" valve *through* its bushing, instead of by the *withdrawal* of the "plug" valve from its bushing or seat.

SECOND. What next may be done to the structure of Patent No. 141,685 ?

A NEW VALVE may be added, which opens when the piston (or diaphragm) makes its EXTREME stroke. This is shown in diagram 7, on the opposite page.

Here, as will be seen, the bushing, or casing, of the main-valve (black) of diagram 6 has been converted into a *separate valve* (of the "plug" variety), and the extreme or "further traverse" of the diaphragm, or piston, has been caused to pull the said plug-valve off its seat, by means of a collar behind it (see lower figure, "Quick-Action"), and to thus open a *larger passage* than before to the brake cylinder.

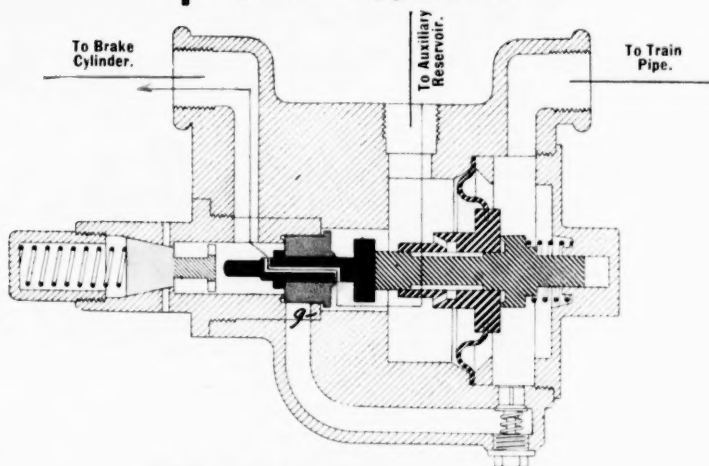

A short, or "preliminary," traverse of the diaphragm (or piston) does *not* unseat the new valve (see second figure), but allows the apparatus to work as it did in the form shown in diagram 6.

THIRD. This alteration of the structure, so as to provide a new valve, has been accompanied by a *change of air-passages*, so that the NEW VALVE will be operative, *when* opened, *to admit train-pipe air* to the brake cylinder.

Train-pipe air (indicated by the blue line and blue arrow) then passes directly from the train-pipe, through the check-valve and under the left side of the emergency-valve (red), to the brake cylinder.

7—Service Application.

7—Quick Action.

A partition, at 9, prevents any interference with the flow of the train-pipe air through the new passage thus opened.

The difference of air-pressures, on opposite sides of the check-valve, causes said check-valve to open (just as in the Westinghouse structure of Patent 360,070). The passage for auxiliary reservoir air is so small, that, while such air passes in sufficient quantities for *service* application of the brakes (or for graduating), it cannot pass in sufficient quantity to maintain equal pressure on both sides of the check-valve, *when* the new emergency-valve (red) is opened, and, hence, the check-valve *then* opens and admits train-pipe air.

Diagram 8, on opposite page, shows the partition 9 merely moved further to the right, and, as this position would cut off the flow of auxiliary-reservoir air for "service applications," a small aperture must now be made through it, as shown.

NOTE. Another way of looking at Boyden's changes in the valve of Patent 141,685, is that he has *changed* the plug "main valve" of that patent into an "Emergency" or "Quick-Action" valve, by providing that it can be opened *only* by the *extreme traverse* of the piston, and by *altering the air passages*, through the insertion of a partition, so that the opening of the valve will admit *train-pipe air* to the brake cylinder; and then, by forming *another valve* out of the *stem* of the original main valve, to admit auxiliary-reservoir air to the brake cylinder for "Service" work. But this comes to the same thing.

This change in the character of the air passages (caused by changes in the location of the partition and making in it a small aperture) is not materially different from the arrangement of air passages shown in the patent in suit, No. 360,070, as will, we think, be apparent from an inspection of the preceding diagrams.

Diagram 9 shows the valve of diagram 8, modified in form, by simply making the emergency (red) valve a *lift* valve (instead of a *plug* valve), and by arranging the air passage from train pipe to brake cylinder so as to go *through* the triple-valve piston, or diaphragm, instead of *around* it. THIS MAKES THE DEFENDANTS' VALVE.

Can any one doubt, after inspecting these diagrams, that the Boyden structure is really the structure of Patent No. 360,070, *under a mere change of form*.

Let us, then, again enumerate these changes, understanding that a mere change of form is immaterial, so far as any departure from the essential features of Patent No. 360,070 is concerned.

FIRST. The release valve (green) has been altered in position so that the "release" is no longer effected by the movement of the main valve (black), as in Patent No. 360,070. It is now effected by the movement of a separate valve (green) at the left-hand of the structure, as illustrated in Westinghouse Patent No. 141,685.

SECOND. The "main valve" (black) for admitting auxiliary reservoir air to the brake cylinder and applying the brakes has been changed in form from a "plug" valve to a "sliding stem valve" (see diagram 6).

Clearly this is an immaterial change, so far as Patent No. 360,070 is concerned.

THIRD. A new valve has been made (diagrams 7 and 8) around, and supplementary to, the stem slide valve, which opens a larger passage of the brake cylinder. This valve opens only on the extreme traverse of the piston.

1

FOURTH. A new air passage (diagrams 7 and 8) has been provided, direct from train pipe to brake cylinder, which is normally closed (during "service" application of the brakes) by a spring check valve, but which is opened (when "quick action" of the brakes is desired) by reason of the fact that train-pipe pressure, on one side of said check valve, preponderates over the slowly admitted pressure from the auxiliary reservoir, upon the other side.

This new passage, which is closed by the check valve, is, in the Boyden valve, located in the centre of the triple-valve piston or diaphragm, whereas in the Westinghouse Patent No. 360,070 the new passage is located *around the edge* or side of the triple-valve piston or diaphragm.

This difference in location of the new air passage is clearly immaterial, as is seen by a comparison of the diagram 9 (which represents the valve of Patent No. 141,685, modified so as to provide a direct passage from train pipe to brake cylinder *through the centre* of the triple-valve diaphragm or piston, as in the Boyden valve), with the diagram 8, which represents the new passage *around the* triple-valve diaphragm or piston.

FIFTH. The *new* valve, which controls or governs the *new* air passage, is one of the "lift-valve" variety instead of one of the "plug valve" variety.

This difference is clearly immaterial, as is seen by a comparison of diagram 8 with diagram 9, and simply results from the change of location of the new air passage, from the side of the triple-valve piston (or diaphragm) to the centre.

The allegation that Boyden has done something substantially new by inserting a *partition*, having a small aperture in it, to restrict the flow of auxiliary reservoir air, for the purpose of obtaining such a difference in pressure on opposite sides of the quick-action check valve as to result in the opening of said check valve, when quick action is desired, is wholly unfounded as a matter of fact.

It is true that the restricted aperture is *in a different place* in the Boyden valve from what it is in the valve of Westinghouse Patent No. 360,070, but this is simply due to the location of the emer-

gency valve and of the emergency air passage, and not to any difference in the plan or mode of operation.

The Westinghouse Patent itself expressly refers to the restriction of the opening for the admission of auxiliary-reservoir air, and to the effect of such restriction upon quick action, in the following words (Westinghouse Patent No. 360,070, Record, p. 788) :

"The feed opening for the admission of air from auxiliary reservoir to the brake cylinder is *purposely* made of comparatively small diameter, it having been determined by experimenting that the initial application of the brakes should not be made with maximum force, and this opening may be made of such size as to apply the brakes exactly in accord with the requirements of the most efficient working."

That the differential pressures, on opposite sides of the quick-action check valve, are the same in the Boyden structure as in the Westinghouse structure of Patent No. 360,070, and that this difference in pressure is due to the restriction of the air passage from auxiliary reservoir to brake cylinder, is fully explained by the complainant's witnesses.

(See Newbury, Record, p. 163, Q. 205 ; Barnes, p. 195, Q. 230 ; Barnes, p. 373, Q. 672 ; p. 374, fol. 580 ; p. 377, fols. 584-5 ; Westinghouse, p. 287, Q. 417.)

As Mr. Westinghouse says (R., p. 288),

"The presence of restricted air passages, for the purpose of creating momentary differential air pressures, is required for the same purpose in the defendants' structures as in that shown in Patent 360,070, and it does not exist in any different degree in any of these structures."

(4) *The First and Fourth Claims are infringed.*

If we have now correctly explained the defendants' valve and its mode of operation, and have correctly indicated the changes which the defendants have introduced in developing the old Westinghouse triple of Patent No. 141,685 into a "quick-action" valve, we shall be prepared to consider the other claims of Westinghouse Patent No. 360,070 ; viz., the first and fourth.

Those claims are in the following words :

"1. In a brake mechanism the combination of a main air-pipe, an auxiliary reservoir, a brake cylinder, a triple valve, and an aux-

iliary valve device, actuated by the piston of the triple valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake cylinder, substantially as set forth."

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve working within the piston stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake cylinder and to the atmosphere, respectively, and an *auxiliary valve actuated by the piston stem and controlling communication between passages leading to connections with a main air pipe and with the brake cylinder, respectively, substantially as set forth.*"

We have italicized those parts of the claims which are in controversy.

Clearly, the defendants' valves have all of the features of both of these claims. They have "an auxiliary valve device actuated by the piston of the triple valve" (first claim), or "actuated by the piston-stem" (fourth claim).

It makes no difference that in one case the triple-valve piston *pushes* this auxiliary valve off its seat and opens the new passage to brake cylinder (as in Patent No. 360,070), nor that in the other it *pulls* such a valve off its seat and opens a similar passage (as in the Boyden structure).

Nor does it make any difference that, in Patent No. 360,070, the "stem," which opens the auxiliary valve, is on the right side of the piston, while, in the Boyden structure, it is on the left.

The auxiliary-valve device is also as "independent" of the *real* "main valve" in the Boyden structure, as it is in the Westinghouse structure.

In both cases, the auxiliary valve is moved by the triple-valve piston and the stem attached thereto, and in each case there is an "independent," quick-action valve, *i. e., independent*, in the sense that there is a "main valve" which does the "service work" of admitting auxiliary reservoir air to the brake cylinders when service work only is required, and another valve which does "quick-action" work by admitting train-pipe air to the brake cylinders when quick action is required.

Even if it were true, as the defendants contend, that, under certain special circumstances, and by special and careful manipulation, the valve 22 (red) of the Boyden structure can *also* (in *some* cases, and by "careful" manipulation) be made to admit only auxiliary-reservoir air to the brake cylinders, yet it is none the less true that such valve is *principally useful* for "quick action," and is "independent" of the sliding stem valve, which is *mainly*, and to the extent of from 90 to 95 per cent., relied upon for "service" work.

Can the defendants escape the charge of infringement if they have a valve which performs "quick action" work, and which is clearly "auxiliary" to, and "independent" of, another and separate valve, which performs at least some (and, as we prove, the principal, if not all of the substantial, part of the "main valve" work), merely because, by some special manipulation, and under some special circumstances, that auxiliary and independent valve can also be made to do some "main valve" work?

The defendants' auxiliary or "quick-action" valve is clearly independent of *one* "main valve," and this, as we show, and as the Circuit Court below held, the *principal* one.

The Court of Appeals were clearly in error (*Rec.*, p. 881, *foot*) when they said that the *principal* function of valve 22 is to do "main-valve" work (*i. e.*, to admit auxiliary reservoir air to the brake cylinder), and that its "quick-action" work is only incidental. *The contrary is true.*

Differences between valves, more marked than those here involved, were disposed of by this Court as immaterial, in *Consolidated Safety Valve Co. vs. Crosby*, 113 U. S., 157.

In that case, the Court said :

"There is one structural difference between the two valves, which is now to be mentioned. In the Richardson valve, *all* the steam which escapes into the open air escapes from the huddling-chamber, through a stricture which is smaller than the aperture at the ground joint. In defendants' valve, the valve proper has two ground joints, one at the inner periphery of the *annulus*, and the other at its outer periphery, and *only a part of* the steam, namely, that which passes through one of the ground joints, passes through the huddling-chamber, and then through the stricture; the other part of the steam passing directly from the boiler into the air through the other ground

joint. But all of that part of the steam which passes into the huddling-chamber and under the extended surface, passes through the construction at the extremity of such chamber, in both valves; the difference being only one of degree, but with the same mode of operation."

* * * * *

"When the ideas necessary to success are made known, and a structure, embodying those ideas, is given to the world, it is easy for the skillful mechanic to vary the form by mechanism, which is equivalent, and is, therefore, in a case of this kind, an infringement."

The defendants' stem slide valve is not the sensitive graduating valve of Patent 220,556.

It remains to consider one contention urgently pressed by the defendant, and which had the qualified approval of the Circuit Court (Judge MORRIS) (Record, p. 844), and, possibly, of the Circuit Court of Appeals (Record, p. 882).

That contention is that the stem slide valve 18, with its apertures, *i, j, k*, of the Boyden structure, is essentially the sensitive poppet valve, inside the "main valve," of the Westinghouse Patent No. 220,556, and hence (as alleged) that the valve 22 of the Boyden structure is only the "main valve" (under a change of form) of the Westinghouse Patent No. 220,556, and prior Westinghouse patents.

The Circuit Court (MORRIS, J.) said on this subject, as follows (p. 844):

"It is probably true that in the Boyden mechanism, the stem valve *i, j, k*, which I take to be the equivalent of the sensitive graduating valve shown in the Westinghouse Patent No. 220,556, October 14, 1879, is so constructed that it may do, *and probably in most cases does do, the work of ordinary breaking*; that is to say that by two or three successive applications of pressure through that smaller and more sensitive valve the brake cylinder is filled and the main valve 22 becomes non-essential, or, if lifted off its seat, is moved very gently; but valve 22 will, if the engineer uses his brake valve *carefully*, do the work of a main valve, as is demonstrated, I think, by the experiments in which the sensitive graduating valve *i j k* was plugged up. So I take it that defendant's valve *i j k* must be held to be the sensitive graduating valve usual in triple-valve devices since the Westinghouse Patent No. 220,556; and the defendant's valve 22 must be considered to be the main valve, and that in defendant's mechanism he has been able, by an ingenious arrangement,

restricting the admission of auxiliary-reservoir air to the triple-valve chamber, to cause the main valve to do both main-valve work, when needed, and to do quick-action work when needed.

"As, by the explicit terms of Claims 1 and 4, Westinghouse has restricted himself, as to those claims, to an auxiliary valve, independent of the triple valve, I hold that the defendant does not infringe those claims.

The Court of Appeals dealt with the subject more briefly (R., p. 882), in the following words :

"We think the Circuit Court was correct in its view that the poppet valve 22 of Boyden is the original main valve of 220,556."

Are those views correct ?

We note the exact position taken by the Circuit Court, and, apparently, approved by the Circuit Court of Appeals.

It was conceded that the stem-valve *i j k* "is so constructed that "it may do, and probably *in most cases* DOES DO, the work of preliminary braking"—*i. e.*, "service" work—and hence that, generally, the so-called "main valve 22 becomes non-essential" *for that purpose*, and that it is only in case the engineer uses his brake valve "carefully" that the valve 22 *can ever* do "main-valve" work.

That it so worked *at all* (even under the exceptional circumstances stated), Judge MORRIS, and apparently the Circuit Court of Appeals, thought was demonstrated by working the Boyden valve with the apertures *i j k* *plugged up*—that is, by rendering *inoperative* the very valve features which, it was conceded, did "main-valve" work "in most cases." The other valve *could then* be made to do "main-valve" work.

But this so-called demonstration, by which the defendants convinced the courts, was very misleading as to the real character of the valves.

The character of a valve (say, the valve 22) is determined by what it does in the structure as actually organized—not by what it does when that organization is materially altered. In the defendants' structure there are obviously two valves; one, the valve *i, j, k*, which, as is conceded by the Courts, does "main valve" work "in

most cases," and, as is apparently conceded, in *all* cases, *unless* the engineer be "careful."

The other is clearly the valve which is *always relied upon* to do "quick-action" or emergency work whenever such work is required.

Is this latter valve 22 any the less a "quick-action" emergency valve, auxiliary to, and independent of, the "main valve" of the triple, because, in a few cases, and by a careful manipulation, it may also be made to supplement the "main valve" work, ordinarily done by the other valve?

If the defendant uses two valves, and one of them be an "emergency valve" and independent of the other, does it make any difference that the emergency valve, while independent of one main valve, for *emergency* work, can be made, on short trains or in exceptional cases, also to do supplemental main valve work?

The Courts below were misled by not giving careful attention to the wording of the Westinghouse claims. They thought that those claims required "an auxiliary valve independent of the triple valve" (Record, p. 485), and as defendants' "emergency" valve was in the case of the triple, they supposed that it could not be the emergency valve of the patent.

What the claims did really require were: An auxiliary valve "actuated by the piston of the triple valve and *independent of the main valve* thereof" (First Claim).

Or, merely,

"An auxiliary valve actuated by the piston-stem" (Fourth Claim).

If the defendants' valve 22 was, as is conceded, really an "auxiliary" valve, and actuated by the piston stem, and adapted for doing, and actually doing, "quick-action" work, as auxiliary to another valve which was relied upon "in most cases" for doing "main-valve" work, the substance of the fourth claim is clearly found.

And, if such auxiliary valve be independent of *even one* "main valve," especially of the one which does main-valve work "in most cases," we have also the substance of the first claim.

But Judge MORRIS and the Court of Appeals were mistaken in supposing that the stem valve *i j k* of the Boyden structure was the equivalent of the "sensitive graduating valve" of the Westinghouse Patent No. 220,556.

As this patent plays an important part in this case, and as its special feature was, in some respects, misapprehended both in the Circuit Court and in the Court of Appeals, a brief statement of its nature will be here attempted.

In this patent, illustrated in the accompanying figure (opposite page 75), which is taken therefrom (Rec., pp. 737-8), Westinghouse shows an air brake which takes power, for *all* conditions of use, from the auxiliary reservoir.

It did *not* use "train-pipe air" at all for the direct purpose of filling the brake cylinders and applying the brakes. The piston of the triple valve actuated a slide valve, known as the "main valve," whose principal office it was to admit air directly from the auxiliary reservoir to the brake cylinder.

A partial or slight traverse of the piston moved the slide or "main" valve a short distance, and caused it to uncover a small aperture leading to the brake cylinder.

A long valve movement, or traverse, admitted a somewhat larger amount of auxiliary reservoir air. As already explained, these passages could not, for constructive reasons, be large.

The Circuit Court of Appeals (in the opinion now sought to be reviewed) spoke of this patent as follows (R., p. 874):

"A study of patent 220,556 will show that compressed air driven by the engineer into the train-pipe passed through the triple-valve of each car to its auxiliary reservoir; *that there was no vent for this train-pipe air into the brake-cylinder except through the auxiliary reservoir, and that this vent from the auxiliary reservoir to the brake-cylinder ordinarily occurred when the triple-valve piston had made but a partial movement or traverse in its chamber.* The text and diagram of 220,556 shows that *even a full or extreme traverse of the piston in its chamber would vent no other compressed air into the brake cylinders, except from the auxiliary reservoirs.*

"The device embraced in patent 220,556, valuable and efficient as it is and was for ordinary work on all trains, with the triple-valve piston in partial traverse, and for emergency work on short trains with the triple-valve piston in extreme traverse; *yet it failed to meet*

12—Release (Brakes Off).

12—Service Application.

12—Quick Action.

②

③

the requirements of the service for emergency work on long trains of fifty large freight cars. For the latter work it was found insufficient in practice, the insufficiency consisting in not acting with sufficient promptitude. It is not for us to explain why the passage of compressed air exclusively from the auxiliary reservoirs to the brake cylinders was not sufficiently prompt on long freight trains. It is assumed in the briefs and testimony that the mechanism of this patent did not suffice for this work. It is admitted on both sides that while the mechanism of 220,556, though effective for the ordinary purposes of braking trains, such as stopping them at stations, slowing them in passing switches and other points requiring continuous movement, and checking them on descending grades, yet that it was not effective for abruptly stopping long trains in sudden emergencies.

But, in addition to the "main" slide valve for uncovering the openings from auxiliary reservoir to brake cylinder by different lengths of movement of the triple-valve piston, there was, in Patent No. 220,556, a subordinate feature of construction to insure greater accuracy.

It was this subordinate feature which was the subject matter of the claims of Patent No. 220,556.

The nature of this feature it is important to understand accurately, because the defendants have based their contention, that their steam valve *i j k* is the equivalent of this sensitive poppet valve, on, what we now hope to show to be, an erroneous view of its character.

A brief review of prior patents of Westinghouse will make this clear.

The admission of auxiliary reservoir air with different (although always LIMITED) rapidity, dependent upon the size of the opening uncovered, from auxiliary reservoir to brake cylinder, was old.

Thus, the Westinghouse Patent No. 168,359 (R., p. 752) describes a triple valve (shown on opposite page), the piston of which operates a slide valve H, which, according as the piston is moved to a greater or less extent, uncovers, to a greater or less extent, the passage *e* to the brake cylinder from auxiliary reservoir.

The patent says (R., p. 754) :

"The position of the piston G in its chamber *a* is regulated chiefly by variations of air pressure on its opposite sides, and, by lessening or increasing slightly the air pressure in *a* below the

piston, the position of the piston may be changed at pleasure, and with it, of course, the valve H."

"It will be observed that the valve H has at h^2 a length and breadth of face such that it may entirely cover the port e . Hence, the piston G may be brought down so that, while entirely closing the supply port s , it shall bring the valve H to a position where it shall uncover only a small part of the port e , or any desired part."

Patent of Westinghouse No. 141,685, dated August 12, 1873 (R., p. 736), illustrates (as already seen) another form of triple valve, in which the "main valve," for fully or partially opening communication from auxiliary reservoir to brake cylinder, is not of the "slide" valve variety, but is of the "poppet" or "plug" valve variety.

This patent "has more particular reference to the construction of devices by which a flow of compressed air from each auxiliary reservoir to its brake-cylinder can be regulated at pleasure, and thereby the brakes be applied with any desired degree of force less than the maximum."

The patent shows a triple valve, operated by a "diaphragm," u (which is a well-known equivalent of a "piston").

The movement of the diaphragm, by reduction of pressure on the other side, causes a tapering "plug" valve o to open to a greater or less extent, according as the diaphragm is moved, communication to the brake-cylinder.

The patent says (R., p. 738) :

"The area of the opening through the port o^1 is regulated by the distance which the plug o is caused to move vertically upward. Hence, if the pressure be reduced but slightly at G^2 , the plug o will be raised but a short distance, and a small amount of compressed air or other fluid will be allowed to pass through and out at the port H^1 . * * * By the use of the taper plug o in the manner described, and by regulating, as can easily be done by the use of suitable cocks, the amount of pressure in the upper and lower parts of the chamber G^1 , it is easy to regulate the amount or density of the air which is permitted to flow through the port o^1 into the brake-cylinder, and consequently easy to regulate and adjust at all times the force with which the brakes are applied, and such force may be varied from the maximum power of the brakes down to the fractional part of a pound in excess of ordinary atmospheric pressure."

It will be perceived, therefore, that long prior to the date of Patent 220,556 Westinghouse had devised several forms of "main

valves " which, by the greater or less extent to which they uncovered an opening or openings into the brake-cylinder (depending upon the extent to which the triple-valve piston moved), regulated at will the amount of auxiliary reservoir air which was admitted to such cylinder.

In the *slide-valve* varieties of triple valve, however (such as those described in the Westinghouse Patent No. 168,359, and in the later patent of the same variety, dated January 11, 1876, No. 172,064 (R., p. 757), there was a lack of certainty in getting to any definite position desired, especially when *slight* variations of pressure only were employed. This was due to the fact that the main valve H was a *slide valve*, and was *subject to air pressure from above* which tended to hold it to its seat.

In Patent No. 220,556 Mr. Westinghouse dealt with the difficulty of operating *such a slide valve* by providing it with an interior auxiliary valve of the "poppet" variety, which could be moved more quickly and with much less pressure than the slide valve itself, and, hence, could be used to regulate the admission of air *after this main slide valve had been once shifted*, without requiring the *main valve* to again move at all.

Patent No. 220,556 (R., p. 762), says :

" It is important in such device that the valve (lettered H in said two patents and herein) which governs the flow of air or other fluid, shall move not only with great certainty to any desired position but also shall move with slight variations of pressure on the piston (lettered G), so that the application of the brakes with any desired power and their ready release may be quickly and easily effected at the pleasure of the engineer.

" To this end I combine with the said valve H, giving it a slight range of motion on its stem, an auxiliary valve operated by the same stem in such manner that a portion of the functions performed in said patents by the valve H may now be performed by such auxiliary valve, the latter moving with practically no resistance, and hence moving more quickly and with less pressure than the valve H itself. The same auxiliary valve is also designed for use under certain circumstances as a leakage valve."*

* These drawings (which are the same as those in the patent, Rec., p. 762) show the parts moving in reverse direction from the corresponding parts of the other drawings and diagrams presented. This will not produce confusion, if borne in mind.

Attention to the drawings and description of Patent No. 220,556 clearly shows the function and operation of this "auxiliary valve," which moves with practically no resistance, because, unlike the main valve, it is not a slide valve nor exposed on one side to air pressure, but is a "poppet."

It is to be noted, however, that this "poppet" valve cannot be used to open communication between auxiliary reservoir and brake cylinder, *until after* the "main" slide valve has moved.

The slide valve H must itself *first* move so as to cut off the opening from the brake cylinder to the open air or exhaust, and *also* so as to open, either partially or fully, communication from the auxiliary reservoir to brake cylinder.

But, *after* this communication has once been opened, either partially or fully, *then* the small interior auxiliary or poppet valve e^1 can be closed or reopened again, by slight movements of the piston, *without requiring any movement of the main valve H itself.*

The patent says (p. 764) :

"When now the valve H is thus shifted, so that the port s shall, to the extent of one-quarter or one-half its capacity, more or less, as is usual when less than a maximum braking force is desired, be thus brought into communication with the port C, and held there until the limited or desired amount of fluid pressure shall have passed into the brake cylinder, *the auxiliary valve e^1 becomes available as a quick and ready means of closing the supply port with certainty, without danger of opening the exhaust.* To this end, a very slight increase or excess of pressure below the piston G—much less, in fact, than is necessary to shift the valve H—will suffice to move the piston G and stem g far enough to close the valve e^1 on its seat e . All ports are thus closed by an almost instantaneous motion, and the brakes remain on with a force corresponding to the amount of pressure previously charged into the brake cylinder.

"In case a slight addition to the operative braking force is desired, either to compensate for loss by leakage or for any other reason, it may be secured by a slight downward motion of the piston G, such as will unseat the auxiliary valve e^1 . In this manner the graduating function may be more advantageously performed than heretofore."

And again (p. 765) :

"But with the explanation already given, it will be seen that the necessity of giving a back stroke to the valve H is wholly obviated, so far as relates to closing the ports and holding in the brake-

cylinder any predetermined or limited amount of fluid pressure, or to increase such pressure at pleasure, *since after the slide-valve H has been brought to the desired position*, as set forth, a slight motion imparted to the piston G, and much less than would be necessary to start the valve H, will suffice to seat and unseat the auxiliary valve e^1 , and so hold or retain in the brake cylinder any desired pressure previously charged therein, or permit the increase thereof at pleasure."

The function, therefore, of the auxiliary "poppet" valve e^1 , *in the slide valve H*, for the purpose of remedying its lack of sensitiveness and its excessive friction, will now, we think, be clearly understood. This auxiliary valve has no function in *initially*, or *without movement* of the "main" valve, opening access from auxiliary reservoir to brake cylinder.

Although it is unseated as soon as the piston G commences to move, yet it admits no air to the brake cylinder, until the slide valve H itself has been moved into the position which uncovers the port s^1 leading to the brake cylinder.

After that has once been done, then this auxiliary poppet valve can be used to close the access to the brake cylinder, without again shifting the slide valve H, or to re-open that communication, without such shifting.

It will thus be seen that the addition to the prior art in air brakes, which was made by Patent No. 220,556, was supplementing a main *slide valve* by an interior poppet valve.

The "sensitive graduating valve" of said patent was a "poppet" valve, working inside of the main slide valve, and there used, because *that kind of slide valve* was slow when delicate action was required. This poppet valve was brought into operation, *only and solely, after* the main slide valve had been shifted to open communication to the brake cylinder.

Now, there is no such construction in the Boyden apparatus, and no need of any such construction.

In the operation of the Boyden structure, the stem slide valve *i, j, k*, must move *first* and, *generally*, is the *only* valve that moves in "service" work.

It is that valve, and that alone, which initially moves to open, and does open, communication from the auxiliary reservoir to brake cylinder.

The valve 22, which surrounds the valve $i j k$, is *not* the true "Main Valve", because it does *not* move *first*, and can not move *at all* (to admit *auxiliary* reservoir air) *until after* the brake cylinders have been substantially filled through the ports $i j k$.

To consider valve 22 of Boyden the equivalent of the *Main Slide Valve* of Westinghouse, and the sliding stem valve 18 of Boyden, with its port $i j k$, the equivalent of the supplementary poppet valve of Westinghouse, is a view which is the very reverse of the construction illustrated in the Westinghouse Patent No. 220,556.

In that patent, the main slide valve opens communication from the auxiliary reservoir to brake cylinder *first*, and it is *only after it has moved* that the interior sensitive poppet valve can be brought into operation at all; and its first movement must then be to close the passage to the brake cylinder—not to open it.

In the Boyden structure, on the contrary, the valve 22 does not move *at all*, until *after* the brake cylinder has been substantially filled with air admitted by the apertures $i j k$.

The Boyden structure has, therefore, no sensitive interior poppet valve for closing and reopening communication, after a main slide valve has been shifted (which is the *only* function of the *poppet* valve of Patent 220,556), because it has no need of any such valve.

The Westinghouse structure of Patent No. 220,556 needed an interior sensitive poppet valve, because its "main valve" was a slide valve, *with air pressure on one side*, holding it to its seat and producing friction. The Boyden slide valve is a stem slide valve, *having equal air pressures on all its sides*, and, consequently, it moves freely.

The valve 22 of the Boyden structure is not the equivalent of the "main slide valve" of the Westinghouse Patent No. 220,556, because it is not relied upon to do main-valve work. The valve $i j k$ confessedly does such work "in most cases." The valve 22 does not do such work at all, except when the engineer is "careful,"

and, as already shown, if it can ever be done, it is only *possible* to do such work on the *front* cars of a long train.

Under such circumstances, it is not "*the main valve.*" It is a "*quick-action*" valve, auxiliary to, and independent of, the *real* "*main valve.*"

The Second Claim of Patent No. 360,070 is not "Fatally Defective."

The ruling on this point by the Circuit Court of Appeals is in the following words (Record, p. 880) :

"We think that when claim 2 of 360,070, in its language describing the action of that device, failed to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston, 'by a further traverse admits air directly from the main air pipe to the brake cylinder,' it was fatally defective, claiming only a result which is public property and not identifying the specific means (his own property), by which the result is achieved."

* * * * *

"But where the inventor falls so far short in his description as to claim only the result which his machine accomplishes, and omits an explicit definition of the *means* by which he does it, as in the case at bar, the Courts have another duty to perform, one which they owe to the public and to the worthy fraternity of inventors, and must decline to give him general rights where he is entitled only to special rights."

We submit that this ruling was entirely incorrect, in holding that Mr. Westinghouse had failed to adequately describe the means by which his result was accomplished.

It is not the office of a claim to *describe* the means. The specification does that. The claim is intended to "*specifically pointed out*" which of the many parts, necessarily *described* in giving a full explanation, are the *essential* features of the invention.

When the claim states, as it does, that the "preliminary traverse" of the piston "admits air from the auxiliary reservoir," and that the "further traverse" of the piston "admits air directly from the main air-pipe to the brake cylinder, substantially as set forth," it refers back to the specification; not, it is true, for a

slavish adoption of the *identical* instrumentalities there described but for an understanding of the essential and substantial features of the means therein illustrated.

"Substantially as described" means not *literally* as described, nor *identically* as described, but "substantially as specified in regard of the combination which is the subject of the claim."

Lake Shore Co. vs. Car Brake Co., 110 U. S., p. 229.

The specification describes, as already seen, certain features of the structure, which confer upon it its new capacity, under the control of the engineer, viz.: (1) the *double* traverse of the piston, (2) a passage, or way of access, directly from train pipe to brake cylinder, and (3) a valve which *controls* that passage.

These features are the essential features of the "means" by which the triple-valve piston, in its "further traverse," acts to perform its function of admitting air directly from the train pipe to brake cylinder.

The form and location of the passage and the shape of the valve and of the *intermediate* connections, are obviously non-essential, and may be varied within wide limits.

A patentee is not, as we understand it, bound, especially where his patent is one of a pioneer character, to limit himself to the mechanical connections by and through which the essential instrumentality, for producing motion, acts upon the instrumentalities for producing the specific result.

The fact that the claim omits to specify, and is not in fact confined to, the specifically illustrated and described connecting mechanism, by and through which the "further traverse" of the piston of the triple valve opens the valve which admits train-pipe pressure to the brake cylinder, does not make the claim "fatally defective;" nor does it enable an infringer, who varies the form of the connecting means, or substitutes other mechanical means, to escape infringement of the claim.

This has been so recently and unanimously ruled in this Court as to need no elaboration.

In *Deering vs. Winona Harvester Works*, 155 U. S. 286, 302, this Court said (p. 302) :

"Defendants further insist that the twentieth claim of this patent is invalid, by reason of the fact that, if the board *d*¹ be construed, as it evidently must, as a board pivoted to the butt adjuster, the combination is incomplete and inoperative, because the means by which it is held and controlled are not stated in the claim. * * * *Admitting that additional elements are necessary to render the device operative, it does not necessarily follow that the omission of these elements invalidates the claim, or that the precise elements described in the patent as rendering it operative must be read into the claim.* If Steward were, in fact, the first to invent the pivotal extension to a butt adjuster, he is entitled to a patent therefor, though the infringer may make use of other means than those employed by him to operate it (*Loom Co. vs. Higgins*, 105 U. S., 580, 584).

"In such case *any appropriate means* for making it operative will be understood. Otherwise, the infringer might take the most important part of a new invention, and, by changing the method of adapting it to the machine to which it is an improvement, avoid the charge of infringement.

"The invention of a needle with an eye near the point is the basis of all the sewing machines used, but the methods of operating such a needle are many, and if Howe had been obliged to make his own method a part of every claim in which the needle was an element, his patent would have been practically worthless. We think it sufficiently appears that Steward was the inventor of the pivoted extension described in the twentieth claim; that the claim is valid and was infringed by the defendants.

"We agree, however, that the defendants made use of a different method of adjusting this extension, which is neither the same invented by Steward nor a mechanical equivalent of the same. We hold, therefore, that the twenty-first claim was not infringed."

The same principles were applied by the Circuit Court of Appeals to a later and less important patent of Westinghouse for an air brake, No. 376,837, and those principles are still more applicable to the earlier and more important patent in suit.

In that case, the Court said (*Westinghouse vs. New York Air Brake Co.*, 63 F. R., pp. 962-969) :

"but the particular means by which this pressure was to be permitted to exert itself, whether continuously or only when a port should be opened, do not constitute an essential part of the invention. Means must necessarily be shown in the specifications, but the identical means or the special devices were not, in the language of *Machine Co. vs. Lancaster*, 129 U. S., 263; 9 Sup. Ct., 299, 'necessary constituents' of the invention, either in the specification or in

the claim. The skill and mechanical ingenuity of constructors of locomotives can, as will be seen hereafter in the examination of other patents and of the infringing devices, arrange different details of mechanical construction by means of pistons, valves, ports and springs, which, adopting the supplemental chamber system first conceived and embodied by the patentee, and a kindred but not precisely the same mechanical method for the movement of the piston, will accomplish the same result. * * * A Court would not be justified in adopting 'a narrow or astute construction' which would minimize the character of the invention, leave its real scope open to trespassers, and thus 'be fatal to the grant.'

In the very late case of *Taylor vs. Sawyer Spindle Co.*, 75 F. R., p. 310, a similar contention of the existence of a "fatal defect" was urged by the defendants, but the Circuit Court of Appeals for the Third Circuit (Judges ACHESON, WALES and GREEN) overruled such defense, saying :

"As a further defense it is contended that the claims sued on must be construed as containing the sleeve whirl, in which case they are not infringed, because the defendant does not use the latter, *or else they have no operative mechanism and are void.*"

"The law on this subject is too well settled to be open for discussion. A patentee is not required to claim the entire machine in each claim. Each of the claims of issue is for a complete combination of the spindle and its supporting tube and devices, and there was no necessity for expressing in terms the devices for revolving the spindle. Any appropriate means for operating it will be understood. The omission of the sleeve whirl *does not affect the validity of either one of the claims*, which belong to that class where reference may be made in the specification to supply in a claim what is plain to any one skilled in the art, is a necessary incident (*Reese Button Hole Co. vs. Globe Button Hole Co.*, 61 F. R., 970 ; *Deering vs. Harvester Works*, 155 U. S., 286)." (The italics are ours.)

Variance from Former Decisions Upholding this Claim.

Our first assignment of error relates to a conflict between this adjudication that Claim 2 is "fatally defective" in matter of form, and an adjudication made by the Court of Appeals in the Second Circuit.

This latter adjudication was made by a "*Per Curiam*" decision of the Court last named (69 Fed. Rep., 715), affirming the allowance of a preliminary injunction by Judge LACOMBE (65 Fed. Rep., 99) under the identical claims here in suit—claim 2 being one of the claims which Judge LACOMBE particularly discussed.* That the Court of Appeals in the Second Circuit adopted Judge LACOMBE's entire decision as to said claim 2, fully appears from the "*Per Curiam*" decision as rendered :

"We agree with the Court below that the defendant's apparatus "is an infringement of the first, *second* and fourth claims of Patent "No. 360,070, and *deem it unnecessary to add anything to the opinion "of Judge Lacombe*" (69 Fed. Rep., 715).

It goes without saying that the allowance of an injunction under any particular claim, and the affirmance thereof on appeal, necessarily implies that, in the view taken by the Court, as to such claim, it was not "fatally defective," nor even *materially* defective.

And the detrimental results, not only to the patentee, but also to the business interests of the railway public, which must follow such a conflict of adjudications, was not the least of the reasons why this Court is asked to review that which is believed to be the erroneous decision.

The Court of Appeals erred, in deciding that the grant of a patent to Boyden, subsequent to the patent in suit, was a decision by the Patent Office upon the question of infringement, and entitled to great respect.

What the Court said on this subject was as follows (Record, p. 879) :

"This question [of infringement] was presented necessarily to the Patent Office of the United States when Boyden applied for a

* Since this brief was written, the Circuit Court for the Southern District of New York (LACOMBE, J.) has rendered a decision on final hearing (*Westinghouse Co. vs. New York Co.*, Oct. 13, 1896), *reciting the variance* in the decisions of the two Circuit Courts of Appeals, but *upholding* the Second Claim as *valid* and infringed.

patent for the device under consideration. That office employs the best experts in mechanics which it can secure in this and other countries. Its examinations are, indeed, *ex parte* in form, but they are, nevertheless, conducted under hot and skilled contestation in every case of importance; and its decisions, though not conclusive, are entitled to great respect. That office, after full examination, awarded a patent to Boyden on the 16th day of August, 1892, for his quick-action improvement on the device of Patent 220,556, and that action by the office was, in effect, a ruling that the Boyden device did not infringe Westinghouse's quick-action Patent Number 360,070. That ruling takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics. That ruling was subsequent to the issuing to Westinghouse of both the Patents Numbers 360,070 and 376,837, four years after the later patent, when the Patent Office had full knowledge of them."

It is not true, as matter of fact or matter of law, that the Patent Office "employs the best experts in mechanics which it can secure "in this and other countries."

Under a system of promotion, regulated by the rules of our civil-service system, ninety-six examiners are employed, at salaries ranging from \$1,400 to \$2,500 per annum (Rev. Stat., Sec. 440).

Whether such low salaries, under our civil-service system, can command the services of the "best experts," etc, is too doubtful to constitute properly a part of an adjudication as to valuable rights of property.

The ruling that the examinations made in the Patent Office, though "*ex parte* in form," "are nevertheless," as stated in the extract above quoted, "*conducted under hot and skilled contestation in every case of importance*," is wholly an error. The only contests which can possibly take place in the Patent Office, under any Act of Congress now in force, are in interference cases, and Boyden and Westinghouse were never in interference. All other cases are *ex parte*, the proceedings therein are secret, and as to them no contest can possibly arise.

These errors, though comparatively small in themselves, lead up to two other errors, both of which are material.

By the grant of a later patent to Boyden, it is stated, in the extract above quoted,

"that the action by the Office was, in effect, a ruling that the "Boyden device *did not infringe* Westinghouse's quick-action "patent number 360,070."

And at that time—that is, at the time this Patent Office action was taken—it will be remembered, this case and this question were then pending in the Circuit Court.

And while so pending, the defendants procured, on the usual *ex parte* applications, the grant of the three several patents already recited, in which they inserted various statements, argumentative and otherwise, as to the relationship of their device to the Westinghouse Patent 360,070, and apparently for the express purpose of using such *ex parte* statements as evidence in their own behalf.

Nor can this ruling of the Court of Appeals be put aside as mere *obiter dicta*, and therefore of no binding force as an adjudicated precedent. Exactly the reverse is true. It is an adjudication as to the proper legal effect of certain evidence, which, with rare exceptions, is introduced into every patent case which is ever tried. Defendant almost invariably has a patent, good or bad as it happens, and defends under it. And this adjudication, made by a court of last resort, unless reversed or corrected, will be binding as such throughout the Fourth Circuit, and more or less controlling as an authority in the other circuits.

The question of infringement, under the law, does not belong to the Patent Office, and, until the present decision was rendered, it has never been so held.

The ruling or decision thus made, and stated with such freedom from ambiguity, coming as it does from a Court ordinarily, in Patent cases, of last resort, is *alarmingly dangerous* to the interests of inventors and patentees everywhere, and is *most dangerous* to those inventions which possess the *highest merit*. What would this Court have said, if it had been asked to decide, in the Telephone cases, that, by the grant of later patents to Dolbear, or to Drawbaugh, or to Edison, or to Gray—and granted *while suits for infringements were pending*—the Patent Office had made a ruling that the Dolbear, or the Drawbaugh, or the Edison, or the Gray telephone "*did not infringe*" the prior Bell

Patent? We mean no disrespect to the Court whose decision we are now calling in question, by saying that, as we understand the law, such a holding is simply revolutionary. If such be the law, then the use of the Patent Office for the purpose of presenting, if not for manufacturing, testimony, to prove an issue upon which the prior patentee cannot be heard upon his own behalf, hereby enjoys the highest judicial sanction which it can possibly receive outside of this Court, and in the hands of the infringer becomes an implement of easy use by which to make, in all cases, a perfect defense. All he has to do is to apply for and procure, at a cost of \$35, a later patent for some further detail of improvement, real or pretended. He can *assert*, in his application, that his "improvement" or "modification" is not an infringement, etc. As the Patent Office has no jurisdiction of the question of infringement (except, of course, in interference cases, and then only for the purposes of the grant), such assertions in a specification are generally allowed to go unchallenged, and are left for the Courts to pass on. The *claim* is usually scrutinized—nothing else is (100 U. S., 671-2). Then, no matter how limited the claim, or how trivial the invention, the later patentee, *by merely getting a patent*, obtains, under the decision now in question, an *ex parte* ruling, not merely that his device involves some patentable additions to, or modifications of, the prior patent, but that it departs so essentially from the *claims* of the prior patent that it does not embody its essential features at all—or, in other words, that it *does not infringe*. By the mere grant of a patent so procured, he would have, under Judge HUGHES' decision, a ruling by the Patent Office of *non-infringement*, which he could properly use as a defense.

Such a defense, so made, has thus been held not merely to raise a *prima facie* presumption that the later patent involves some patentable differences from the prior patent, but that its grant, though not conclusive, is *prima facie*, at least, sufficient as a defense; and this ruling has been made by a Court of last resort; and, if the error be not corrected, it will work irreparable injury, alarming both

in amount and extent, to the most meritorious inventors of our nation, or of the world.

The facts, upon which this singular decision was made, are correctly stated by Judge MORRIS in his decision, and his ruling thereon may properly be quoted here as being substantially correct in its application of the law to those facts. Judge MORRIS (66 F. R., 1006, 1007) says:

"It is further urged that in a doubtful case the scale should be turned by the fact that, subsequent to the date of the patent in suit—indeed, more than two years after the institution of this suit—Patents Nos. 481,134 and 481,135, August 16, 1892, were granted to Boyden for the mechanism now used by the defendant.

"Boyden was entitled to patents for whatever was a patentable novelty in the devices by which he was able to make his valve 22 answer for both service and quick-action work in connection with the restricted passage B, and for any other patentable novelty in the forms of his mechanism. The widely different forms in which he has illustrated his devices in the two above-mentioned patents show that—taking what Westinghouse had discovered and demonstrated to be the underlying principle of a quick-action brake—a skillful and inventive mechanic can devise many forms for applying it.

"But, in his specification of Patent No. 461,135, Boyden alleges that his device differs essentially from Westinghouse's Patent No. 360,070, and involves a new mode of operation. *The question whether it does or does not was the very question then pending in this suit*; and, so far as the Examiner passed upon it, in allowing the specification to stand, he did so upon the *ex parte* application of Boyden and unassisted by testimony as to the state of the art at the date of the Westinghouse Patent, and without testimony as to the scope of the Westinghouse quick-action invention and its great importance and merit, and, therefore, without the opportunity of judging whether or not it was a pioneer invention of a fundamental character, entitled to construction co-extensive with the invention, or was simply a patent for an improvement in a known art, to be restricted to the form of the device shown in the model and illustrations."

"The determination of that question is the starting point in the consideration of the controversy, and, in my judgment, the fact that Westinghouse was the first discoverer of the vital underlying invention should turn the scale in his favor."

Contrasting with this the ruling made by the appellate tribunal, it is respectfully, but urgently, submitted that an error, in its probable results so fraught with danger to the most meritorious

inventors known to the law, should not be allowed to pass without correction ; and this is the only Court where it can be authoritatively corrected.

Not only is it true that the Patent Office has no authority to decide, or even pass on, a question of infringement for the Courts, but it is equally true that the Patent Office is not authorized to make or create testimony for the Courts.

While the decision herein complained of does not go to the extent of holding that a Patent Office ruling is *binding* on the Courts, and, in fact, says that it is not "conclusive," it does give to such ruling an effect which, to say the least, has no foundation in law, and also is highly pernicious. In the sentence next following the clause last quoted, Judge HUGHES says of this Patent Office ruling that it "takes rank here as the testimony of experts of the highest experience, skill and knowledge in mechanics."

It would seem to be almost needless to suggest that, if a subsequent improver on a pioneer invention can, by the mere *ex parte* act of procuring a subsequent patent, especially *after being sued*, make or create "testimony" for himself—and testimony which may "take rank" in a Federal Court as that "*of experts of the highest experience, skill and knowledge in mechanics*"—then one of the great safeguards erected for the protection of patented property is entirely destroyed. *On mechanical questions the law knows no higher testimony than that which is thus defined ; and hence, when such testimony is furnished, it cannot successfully be rebutted.*

And if this be a correct statement of the law, then, in patent cases, under the issue of infringement, the Courts will have little to do (except in cases of *manifest error*) but to register and enforce the *ex parte* rulings of the Patent Office.

Miller vs. Eagle Manufacturing Co., 151 U. S., 186, stated the rule that the grant of the later patent merely raised "a *prima facie* presumption" of the existence of a "patentable difference" in the later patent (p. 208). But a "patentable difference" does not negative the charge of infringement.

In other branches of the case, this Court distinctly declined to follow and apply a ruling of the Patent Office as to the existence of patentable difference between two patents issued by the Patent Office (p. 202).

It has often been ruled that an apparatus is none the less an infringement because it embodies an improvement, and has been patented as such.

The decision of the Circuit Court of Appeals of the Fourth Circuit goes far beyond any decision of this Court in attributing weight and value to the *ex parte* rulings of the Patent Office.

The decisions heretofore made by this Court are believed to be in strict accord with the views we are seeking to present.

The question arose in *Blanchard vs. Putnam*, 8 Wall., 420. Mr. Justice CLIFFORD, in rendering the opinion of the Court (p. 426), said :

" Attempts are often made in the trial of patent cases to introduce such collateral issues on the question of infringement, but they are irregular and cannot be sanctioned, as the only proper comparison on that issue is of the defendant's machine with that of the plaintiff, as prescribed in the pleadings. What the jury have to determine is, does the machine of the defendant infringe the machine of the plaintiff; and, if it does not, then the defendant is entitled to a verdict; but, if it does infringe the plaintiff's machine, then the plaintiff is entitled to his remedy, and it is no answer to the cause of action to plead or prove that the defendant is the licensee of the owner of another patent, and that his machine is constructed in accordance with that patent.

" Controversies between litigants in court cannot be completed in that way, nor should the plaintiff be subjected to such outside issues, as he is clearly entitled to a verdict when he has proved that he is the original and first inventor of his improvement, and that the defendant has infringed his patent."

The present case comes exactly within the rule thus stated, in these essential features :

- (1) A pioneer patent to complainant.
- (2) A structure or device made by defendant.
- (3) An issue of infringement raised thereby.
- (4) A later patent under which defendant claims to be working.
- (5) A case for final disposition, not for the preliminary injunction.

Under these facts and conditions, *Blanchard vs. Putnam* says that the patent under which defendant claims to be working is not admissible in evidence *at all, under the issue of infringement.*

Later cases which *look like* modifications of this rule, relate, for the most part, if not entirely, either to some side or collateral issue, or else are exceptional in their nature.

In *Boyd vs. Tool Co.*, 158 U. S., 260, neither party was a pioneer, and both applications were pending at the same time—a very different case.

In *Parcement Co. vs. City of Elizabeth*, 4 Fish., 189, cited in *Boyd vs. Tool Co.*, the question arose *on a motion for a preliminary injunction.* In such proceedings, presumptions sometimes count as evidence, and hence a patent to defendant is worth something in support of a presumption.

But on final hearing, or what is practically the final disposition of a case, mere presumptions do not count for much. And even in *Miller vs. Eagle Co.*, it was merely referred to as a confirmatory consideration, and then only as of a *prima facie* character.

In *Woolensack vs. Reiher*, 115 U. S., 96, the effect to be given to a Patent Office decision arose under a question of reissue. More than two years had elapsed between the date of the original patent and the date of the reissue. Proofs satisfactory to the Commissioner of Patents had been submitted to the Patent Office, so as to account for the delay, and the Commissioner, being satisfied with those proofs, had granted the reissue. These facts were set up in the bill. Defendant demurred, and the Supreme Court, in sustaining the demurrer, after reciting the facts as above stated—that is, the decisions which had been made on the proofs so submitted—added the following (p. 101):

“ But this does not satisfy the law. The question as to whether the delay had been reasonable or unreasonable is for the Court to determine, upon the special circumstances brought to its attention, *and it cannot substitute the decision of the Patent Office upon that question for its own.*”

Hence it is believed that the law of *Blanchard vs. Putnam* is still the law of the land. And even if the later decisions cited *supra*

have tended to modify it, it has never been modified as applicable in a suit on a pioneer patent, and, still further, has never been so far modified that a grant of a patent beomes "testimony of high rank" as establishing non-infringement in a Federal Court, and, still more so, when the later patent is not procured until more than two years after suit is brought.

It is submitted that the effort to raise *ex parte* departmental decisions to, practically, the rank of adjudications, which are authoritative as "testimony" in Federal Courts of last resort, embodies so great and dangerous an error as to create an unusually urgent call for the intervention of this Court, by the exercise of its statutory powers of review.

And it is also submitted that the decision rendered hereon by Judge MORRIS, as quoted above, is substantially correct and should be affirmed.

**Patent Office Proceedings, in the Application for
Patent 360,070, Contain Nothing Which Require
Any Other Than a Broad and Liberal Construc-
tion of the Claims Here in Issue.**

The particular form of embodiment of the Westinghouse quick-action invention, shown and described in Patent 360,070, contains an emergency valve which is *not integral* with the main valve of the triple valve; that is to say, the two are not made of one and the same piece of metal. But Mr. Westinghouse was fully aware of, and recognized, the fact at the time, that whether the two valves were made integral or non-integral (that is, of one piece of metal, or two pieces of metal) was wholly immaterial, and he stated this fact in his specification, as originally filed. Thus, he said (Rec., p. 714):

"Further, while in the specific construction described and shown, the function of admitting air from the main pipe is performed by a valve separate from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve integral with the main valve and

formed by an extension thereof, would be included in and embody the essential operative features of my invention."

This application was filed November 19th, 1886.

Under date of January 14th, 1887, the Patent Office wrote a letter, running as follows (Rec., p. 717, fol. 1172) :

" Claims 1 & 2 are anticipated by patent No. 280,285 to G. A. Boyden, June 26th, 1883 (steam & air brake attachments).

" It is desirable that a working model of the triple valve be furnished."

Claim 1, which was thus objected to, read as follows (Rec., p. 714, fol. 1166) :

" 1. In a brake mechanism the combination of a main air pipe, an auxiliary reservoir, a brake cylinder and a triple valve provided with a device for admitting air directly from the main air pipe to the brake cylinder, substantially as set forth."

This claim did not, in terms, as do the claims in suit, point out that the " device " is one for producing " quick action," nor that it is operated by the movement of a triple-valve piston.

This action of the Patent Office led to a re-examination of the claims as drawn, and it was then found that, while claim two was not open to objection, claim one was, *under the literalism of its terms*, broad enough to cover certain pre-existing *automatic-brake* mechanisms, but which, confessedly, did not *produce quick-action*. *In its literalism*, it was met by Mr. Westinghouse's own patent of 1875, No. 168,359—a patent issued ten years before quick-action was even thought of. And the Boyden Patent, which was cited, No. 280,285, was equally barren of the invention in dispute, as Mr. Boyden himself has testified in the present case (Rec., p. 497, Q. 8).

Thus, on account of a failure to distinguish, in express words, the quick-action invention from previously patented mechanisms which confessedly did *not* contain quick-action, the original first claim was erased and the present first claim was inserted. Also, disclaimer was made of the subject matter of Patent No. 280,285 (Rec., p. 717, fol. 1173 and p. 720, fol. 1177).

Thus, the technical objections to the issue of the Westinghouse Patent, as formulated in the Patent Office letter of January 14th, 1887 (Rec., p. 717, fol. 1172), were wholly obviated.

But another objection seems to have been found, which, though put in writing by the Patent Office Examiner, was made the occasion of another amendment. It appeared that the unwritten rules of Patent Office practice forbade the description, in a specification, of modifications which were not illustrated in the drawings. This rule was merely for the convenience of the Examiners in making their examinations, since they chiefly used the drawings for this purpose, and a modification, though described in the specification, was liable to be overlooked if not illustrated in the drawings. Besides, whether a proposed modification was or was not a mechanical equivalent, was a question which belonged to the Courts and not to the Patent Office. If it was an equivalent, it would come within the scope of the claim, by operation of law.

And, upon the Examiner calling attention to the rule of Patent Office practice, above referred to, the above-quoted reference to an *equal valve*, as capable of being used in lieu of a separately made valve, was erased from the Westinghouse specification.

Hogan, Rec., pp. 277-280.

Thus, three, and only three, amendments were made.

1st. A claim, which was inadvertently so phrased that by its generalism it covered or included a pre-existent *non-quick action* brake, was erased as soon as the error was discovered, and a claim which *excluded* such *non-quick-action* brake was substituted therefor.

2d. The prior patent cited by the Office (Boyden, No. 280,285 of 1883), and admitted by Boyden himself to be *non-quick-action*, was disclaimed.

3d. Under one of the technical requirements of the Patent Office, no assurance was made of *the description* of a possible modification, simply because the drawings of the patent did not contain a view or picture of such modification,—thus leaving that modification to be controlled, if at all, by the doctrine of equivalents.

The 2d in number of these three amendments is not regarded as a fact of importance, either by the Circuit Court or by the Court of

Appeals, and hence may be disregarded ; but as to the other two, the 1st and 3d, the Court of Appeals gives to them a scope and effect much beyond what we believe to be required by law, and equally beyond the strictest requirements of any equitable considerations which can be presented.

And, in their discussion of this part of the case, the Court of Appeals unhesitatingly awards to Mr. Westinghouse the highest possible rank as a pioneer inventor. Thus the Court says (Rec., p. 880, fol. 1419) :

"That this invention of Westinghouse, thus undefined, is one of the highest value to the public, and that it is a pioneer one in the art of quick-action air brakes is not denied, and is conceded. It is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal protection from the Courts in construing the claim."

Continuing in the same liberal tone, the Court states clearly and forcibly certain favorable rules of construction which are to be applied in support of a pioneer invention (*Ibid*).

"If an inventor is ambiguous or obscure, or halt or limp in his language of description the Courts will help him out and so construe the claim as to give distinct identity to his device. If there be a doubt in the mind of the Court or of a jury on the issue of mechanical equivalency the Court will give and instruct the jury to give the benefit of the doubt to the pioneer inventor."

Thus far we have but little to except to. But the next sentence which, for convenience of reference, we designate as (A), and the two following paragraphs which, for like reason, we designate as (B) and (C), are, in their relationship to this case, open to comment. They run as follows (Rec., pp. 881, 882) :

(A) "But where the inventor falls so far short in his description as to claim only the result which his machine accomplishes, and omits an explicit definition of the *means* by which he does it, as in the case at bar, the courts have another duty to perform, one which they owe to the public and to the worthy fraternity of inventors, and must decline to give him general rights where he is entitled only to special rights."

(B) "The inventor in the present case seemed himself to feel that his claim was too broad in terms. In his original application for patent 360,070 his first claim was couched in this language : 'In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve provided with a device

admitting air directly from the main air pipe to the brake-cylinder.' This language covered *any device* which might accomplish the object mentioned, and he found it necessary to erase it from his specification, and to substitute claim 1 as it now stands."

(C) "In the same specification Westinghouse had also used this language: 'Further, while in the specific construction described and shown, the function of admitting air from the main pipe is performed by a valve *separate* from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve *integral* with the main valve and formed by an extension thereof, would be included in and embody the essential operative features of my invention.' Here again is a claim for a function irrespectively of the mechanical means used in accomplishing it, which the inventor found it necessary to erase from his specification. In the suit at bar he virtually asks the court to restore to his claim the two erasures which he felt himself unable to sustain at the Patent Office. Our duty to the public and inventors at large forbids our doing so."

The first, (A), of these three extracts is, in substance, a repetition of the ruling previously made as to claim 2—that it is "fatally defective," etc. We have discussed this point elsewhere (*supra*, p. 10), and have there shown, as we believe, (1) that claim 2 is *not* a claim for "*only the result*," and (2) that it *does* contain a sufficiently explicit designation of "*the means*," and (3) that, under the invention question—"conceded" by the Court of Appeals to be "*one of the highest value to the public*" and "*a pioneer one in the art of quick-action brakes*"—Mr. Westinghouse is entitled not merely to the limited "*special rights*" which that Court is willing to give him, but also to those "*general rights*" which are co-extensive with his invention.

The extract (B) contains very little that requires comment. We cite it, in passing, merely to point out the fact that this ruling contains nothing which even tends to limit the construction of either claim 1 or claim 2 *in accordance with their terms, and with the award of each of the full benefit of the doctrine of mechanical equivalents*.

We come now to the extract above designated as (C), and herein our fifth assignment of error, as submitted with the petition for a writ of *certiorari*, is in point, the same reading as follows:

"FIFTH. As further matter of error herein, and as a matter irreconcilably at variance with the ruling of the Circuit Court of Appeals in the First Circuit, your petitioners further submit that manifest error was made by the said Circuit Court of Appeals for the

Fourth Circuit in holding as matter of law that *the mere erasure* from the original specification of a description of a proposed modification operates as a *disclaimer* of such modification."

It is believed that the following considerations are controlling :

1. We have already explained why this erasure was made—merely in compliance with a technical rule of the Patent Office that, not being separately illustrated in the drawings, it could not remain in the description. The *act* of erasure cannot have any efficiency, beyond the *reason which required it*. The erased matter was not alleged to be *untrue* ; hence there can be no presumption, from mere erasure, that it was otherwise than true. And if true *then*, it is true *yet*.

2. The truth of the matter so erased has never been called in question, either by any testimony introduced into this case or in any other way. And its truth being universally admitted, it logically follows that the *integral valve* is, in fact, the mechanical equivalent of the separate valve, and therefore, as such, comes within the scope of the valve.

3. Erasure and disclaimer are two different things. In no respect are they synonymous. In this case, Mr. Westinghouse, under rules of Patent Office practice, was not allowed to state a certain fact in a certain way—the truth of the fact not being questioned. The fact remained true, and Mr. Westinghouse remained at liberty to assert and maintain its truth at all other times and places. He was simply not permitted, for technical reasons, to state it *then and there*. Hence he erased it.

To convert this into a disclaimer, such as to deprive Mr. Westinghouse of any right therein, there must be on his part some further act of renunciation or disavowal, in respect of the thing referred to in the erased matter, such as would create an estoppel.

His right to the integral valve, as a mechanical equivalent of the separate valve, is a *property* right which the law gives him, and of which the law will not divest him by mere inference or implication.

4. This exact question arose recently in the Court of Appeals, First Circuit, and it was there decided by an elaborate and exhaustive opinion, that a mere erasure is *not* a disclaimer.

Reece Button-Hole M. Co. vs. Globe Co., 21 U. S. Ap., 244 :

The discussion of this particular question, in the case thus cited—too long to be here quoted in full—will be found at pages 369-373 of 21 U. S. App. Briefly, it is to the effect that the rule of *Leggett vs. Avery*, 101 U. S., 256, as to cases where broad claims are made, rejected and erased, and *narrower claims are inserted, or where positive disclaimers are made*, is that, in such cases, the limitations thus voluntarily placed on the scope of the patent by the patentee ought not to be and cannot be disregarded by the courts ; but that, while this is true, it is also true that the rule ought not to be extended to the mere erasures or alterations (1) which are made as to matters of detail, or (2) which, under Patent Office practice or usage, are required for making the specification conform to the drawing, and (3) least of all should such rule be extended and applied to what are known as "pioneer" patents—one of which the Westinghouse confessedly is. The Supreme Court, so far as our search can discover, has never as yet extended the *Leggett vs. Avery* rule to any one of the class of cases last above referred to, and two Circuit Courts of Appeals have decided that it ought not to be done—one in the *Reece* case, and the other in a case presently to be cited.

From the *Reece* case (*supra*, p. 370), we extract two short sentences which indicate the conclusion reached by that Court :

"Nevertheless, it defeats the very essence of this rule to extend it to what was inserted inadvertently, or to push the construction of what was thus inserted in one direction, when it is plain from the whole transaction that the parties inserting were looking in another."

* * * * *

"Courts ought, therefore, to be the more careful, under circumstances like those at bar, to give a patentee the benefit of all the equities which can be raised in his behalf by any reasonable implication from what appears on the face of the amendments, or from the transaction as it passes through the Patent Office."

And this limitation of the *Leggett vs. Avery* rule, as formulated in the *Reece* case, is approved, adopted and applied by the Circuit Court of Appeals in the Sixth Circuit.

McCormick Harvesting M. Co. vs. Aultman, 37 U. S. Ap., 299, 344, 345.

In this case, the subject is reconsidered as fully as it was in the *Reece* case, and in disposing of it the Court says (pp. 344, 345) :

"Whether he specifically claims in his patent the benefit of equivalents or not, the law allows them to him according to the nature of his patent. If it is a mere improvement on a successful machine, a mere tributary invention, or a device the novelty of which is confined by the past art to the particular form shown, the range of equivalents is narrowly restricted. If it is a pioneer patent with a new result, the range is very wide and is not restricted by the failure of the patentee to describe and claim combinations of equivalents. Nothing will restrict the pioneer patentee's rights in this regard save the use of language in his specification and claims which permits no other reasonable construction than one attributing to the patentee a positive intention to limit the scope of his invention in some particular to the exact form of the device which he shows, and a consequent willingness to abandon to the public any other form, should it be adopted and prove useful. Instances of such a limitation may be found in *Keystone Bridge Company vs. Phoenix Iron Company*, 95 U. S., 274, and in *S. N. Brown & Company vs. Stilwell & Bierce Manufacturing Company*, 6 U. S. App. 427; s. c., on petition for rehearing, 16 U. S. App., 234. But there is no such limitation in the patent under discussion, and the rule applies which was so fully explained in *Winans vs. Denmead*, 15 How., 330, 342, where the Court said: "Patentees sometimes add to their claims an express declaration to the effect that the claim extends to the thing patented, however its form and proportions may be varied. But this is unnecessary. The law so interprets the claim without the addition of these words." Again, in *Goodyear Dental Vulcanite Company vs. Davis*, 102 U. S., 222, 230, the Supreme Court said that a patentee was protected against equivalents whether he claims them or not. A most satisfactory discussion of this general subject may be found in the opinion of the Circuit Court of Appeals of the First Circuit, in *Reece Button Hole Machine Company vs. Globe Button Hole Machine Company*, 21 U. S. App., 244, where Judge PUTNAM, on behalf of that Court, examines the two lines of cases of which *Winans vs. Denmead* and the *Keystone Bridge Company vs. Phoenix Iron Company*, *supra*, are respective types, and reconciles them so far as they may be reconciled."

And the *Reece* ruling herein is being extensively applied in cases at circuit.

Rhodes vs. Lincoln Co., 64 F. R., 218, 220.

Campbell Printing Press Co. vs. Marden, 64 F. R., 782, 785, 786.

New Departure Bell Co. vs. Bevin Co., 64 F. R., 859, 864.

Richardson vs. Am. Pin Co., 73 F. R., 476, 478.

Bonsack Machine Co. vs. Smith, 70 F. R., 383, 396.

Westinghouse vs. Boyden Co., 66 F. R., 997, 1006.

5. The ruling herein of the Court of Appeals for the Fourth Circuit, especially as applied to pioneer inventions, is strongly in derogation of the rulings of this Court in a large class of cases, of which *Morley Machine Co. vs. Lancaster* (129 U. S., 263) is one. It would, if carried out, completely withdraw the protective influence of the doctrine of mechanical equivalents from the most useful and beneficial inventions which we have, simply on account of a mere technicality of detail, unimportant in itself, and which, so far as it concerns the defendant, is utterly devoid of equity and, as related to the patent, is directly contrary to equity.

6. The identical question here presented, under the same patent and on the same facts, was the subject of judicial inquiry in the Second Circuit nearly two years ago in *Westinghouse Air-Brake Co. vs. New York Air-Brake Co.*, 65 F. R., 99. The case was heard by Judge LACOMBE on a motion for a preliminary injunction, but every fact and argument that could be urged on final hearing was then presented. Judge LACOMBE, in overruling this defense, expressed himself with his usual clearness and cogency (65 Fed. Rep., 101):

"Defendant relies upon the rejection by the patent office of the original first claim of 360,070 and the substitution of the present first claim as an abandonment of the fundamental broad invention therein disclosed. When, however, the reference on which the patent office rejected the original first claim (Boyden's patent No. 280,285) is consulted, it is apparent that the essential change in the claim is the phrase used to differentiate 360,070, an invention to be used 'in the application of the brake,' from Boyden's invention, whose object was to provide for replenishing, 'while the brake is on,' the air reservoir or brake cylinder, when the pressure is reduced by leakage, etc. There is nothing in the file wrapper or contents to show that the patent office required or that the inventor agreed to abandon what was the great feature of his invention—the emergency valve—or to give up whatever range of equivalents his patent might, as modified, fairly cover. Both these patents 360,070 and 376,837 are broad ones, and their claims should be construed to cover the meritorious invention they disclose, unless the language of such claims precludes such a construction. The only question really open on this motion is that of infringement."

Defendants appealed. In the Circuit Court of Appeals, the action of Judge LACOMBE under Patent 360,070 was affirmed, "*Per Curiam*," which action certainly implies no serious dissatisfaction in

the Court of Appeals with the rulings of Judge LACOMBE under that patent.

7. It is submitted that the decision of Judge MORRIS on this point, as briefly expressed in this case at circuit, should be affirmed. Referring to all three of the amendments above summarized, he says (Rec., p. 851) :

"The amendments made to meet the objections of the Patent Examiner are not to be construed to disclaim the patentee's actual invention, if such construction can be avoided without doing violence to the obvious meaning of the language.

"*Lake Shore Railway Co. vs. Car Brake Co.*, 110 U. S., 229-236.

"*Reese Buttonhole Machine Co. vs. Globe Buttonhole Co.*, 61 Fed. Rep., 956."

Defendants' "Partition 9" and "Restricted Port B." "Momentary Differential Pressures."

These considerations have already been incidentally discussed ; but the importance ascribed to them by the defendants, renders a separate and further discussion not inappropriate.

After perusing the proofs in this case, there can be no reasonable doubt as to the correctness of three or four propositions.

1st. That Mr. Boyden, in getting up or designing the defendants' quick-action valve, did so with a full knowledge of the invention here in controversy. In fact, he admits as much (Rec., pp. 514-516, Q. 25).

2d. That in getting up or designing this valve, he studiously sought to embody in it the salient features of the "automatic" brake, and also to combine therewith the direct admission of train-pipe air to the brake cylinder, to effect the "quick-action" operation, when and only when unexpected emergencies in the running of the train should require it.

3d. That he sought to do this by a form or structure of apparatus which should retain every essential element of operation and of function which is to be found in the Westinghouse apparatus,

and retain it so perfectly as, in practical use, to be interchangeable with it, and to operate with it in the same train, to do the same work, in the same way, and under identically the same conditions. And it is so stated in defendants' catalogue (Rec., p. 489, last paragraph but one) :

"The actions of this valve in graduating, full service application, quick action and the release, are the same as the new Westinghouse quick-action valve, thereby producing the same results in breaking, which renders cars equipped with the two valves perfectly interchangeable—the hose couplings being the same."

4th. Also, that he sought to design a form or structure of quick-action valve which ocularly, or *to the eye*, should differ from the Westinghouse in as many of its details as possible, but *without loss of any essential function or feature of operation.*

Thus far, we think there can be no dispute. Mr. Boyden, himself, would probably admit this much, if he has not already done so.

Boyden's assumed position, as we understand it, involves two further propositions, in substance as follows :

5th. That, in making these changes, he has made a new substantive invention of his own, which in defendants' proofs is referred to as "The Partition 9" and "The Restricted Port B," and which, as alleged, produce, or result in, a novel operation, referred to as "Momentary Differential Pressures."

6th. That, in doing this, he has not used any substantial part of the Westinghouse invention.

In reply we say :

(1) A "Restricted Port," by or through which "Momentary Differential Pressures" are alleged to be secured, is found in the Westinghouse Patent 360,070. It is there found in substantially the same combination in which defendants use it, and doing the same work of regulating pressures, and doing it in the same way. Hence Boyden's pretense that this is his invention is not sustained by the facts.

A short explanation will make this clear.

In the emergency use of the brakes, air under pressure enters each brake cylinder from *two sources of supply*, the *auxiliary reser-*

voir and the *train pipe*. Just at the instant of the shifting of the triple valve to quick-action position, the *auxiliary reservoir* pressure is the greater, since it is normal, say 70 pounds, while *train pipe* pressure has been reduced by the venting done by the engineer, who has let out 15 or 20 pounds, so bringing it down to 55 or 50 pounds. Now, it is obvious that air at 55 or 50 pounds pressure cannot be charged into the brake cylinder from the *train pipe*, to produce "quick action," if *auxiliary reservoir* pressure at 70 pounds is also admitted at the same time *with equal freedom*. Hence, in order that the *lower* air pressure from the *train pipe* may be vented into the brake cylinder of each car, so as, through a lowering of *train-pipe* pressure on that car, to hasten brake action on the *next* car, it is absolutely necessary that the admission of *auxiliary reservoir* pressure be *choked*, or held back or occur *slowly*, while, for a moment, *train-pipe* pressure flows in *freely*. In other words, in the quick-action use of the brake, some one port between *auxiliary reservoir* and brake cylinder must be smaller in cross-section than the smallest port leading direct from the *train pipe* to the brake cylinder. With the ports so proportioned, *auxiliary reservoir* pressure will be choked or admitted slowly, so that, for a short time, the *lower* pressure from the *train pipe*, entering by the larger port, will pass into the brake cylinder in advance of the *higher* pressure from the *auxiliary reservoir*. In a moment ("momentarily"), the difference ("differential") of pressures, between *train pipe* and brake cylinder, becomes equalized, the check valve closes, and the discharge of air from the *auxiliary reservoir* to the brake cylinder then continues until the maximum braking pressure is reached.

This is what we understand that defendants' experts refer to when they talk about "Momentary Differential Pressures." Possibly they invented this three-worded name, but *the thing itself*—that is, "the restricted port" and *its operation*—is found in the Westinghouse Patent, and in every Westinghouse quick-action triple valve ever made.

To make this clear, we will refer to drawing No. 92, opposite the following page, which is a reproduction of Fig. 2 of the patent in suit (360,970), but with the devices in quick-action position.

360,070: Quick Action Position

Drawing No. 92.

Defendant's Triple Valve,
Quick Action Position.

Drawing No. 95.

The blue line indicates the line of direct flow from train pipe to brake cylinder, and the port 42 and passage 46 are the passages of least capacity therein.

The red line indicates the then existing line of flow from auxiliary reservoir to brake cylinder, and the port 35 is the smallest port therein.

Inspection will show to the eye that the feeding ports 31 and 35 are much smaller than either the port 42 or the passage 46. If we measure them, taking the dimensions shown in the patent, we will find that 35 is less than one-ninth the size of either 42 or 46. In other words, port 35, which holds back *auxiliary reservoir* pressure, is less than one-ninth the size of the ports which admit *train-pipe* pressure directly to the brake cylinder.

Furthermore, the patent itself, 360,070, is careful to direct that feeding port be made, as it is made, of "comparatively small diameter." At page 4, line 57, of the patent (Rec. p. 788, top of page), it is specifically directed that—

"The feed opening for the admission of air from the auxiliary reservoir to the brake cylinder, is *purposely made of comparatively small diameter*, it having been determined by experiment that the initial application of the brakes should not be made with maximum force, and *this opening may be made of such size as to apply the brakes exactly in accord with the requirements of the most efficient work.*"

Then, as *train-pipe* pressure flows freely through ports 42 and 46, such pressure soon becomes equalized in the brake cylinder. Then the "momentary differential" condition of things ceases, the check valve 49 closes, and *auxiliary reservoir* pressure continues to flow in normally.

Defendants have not only appropriated the Westinghouse quick-action invention, as a whole, but they have also copied this specific feature of the Westinghouse quick-action valve, with no change whatever, except *in the location* of the small or restricted port. Drawing No. 95, on the opposite sheet (taken from defendant's own "illustrative cuts," No. 8, Rec., facing p. 498), shows defendant's valve. The restricted port B, in the partition 9, corresponds, in all essential respects, to the Westinghouse restricted feeding port 35. It

is, in the quick-action operation, located in the line of flow of pressure from the auxiliary reservoir to the brake cylinder, as illustrated by the red line, just as is the Westinghouse port 35. It is much smaller in size than is defendants' emergency valve port 22, just as Westinghouse port 35 is smaller than his port 42. Defendants may have a slightly greater difference in the relative sizes of the two ports, but this is only a matter of degree. The difference itself is material and substantial in both cases; it is utilized in both to do the same work, at the same times, and in the same way.

These facts, as we submit, effectually disprove Boyden's pretense that this is his invention. It is not. It is found in the patent in suit. He may have invented the particular form of partition 9, but the Court will observe that the partition 9 has no utility whatever, except as it contains the restricted port B, which simply provides for holding back auxiliary reservoir pressure, and thereby secures what Boyden calls "Momentary Differential Pressures." But the restricted port was not his invention, nor was he the first to employ "Momentary Differential Pressures," in operating quick-action brakes. Westinghouse preceded him in both.

Complainants' proofs in support of the above are full and complete.

Newbury, Rec., p. 163, fol. 247, Q. 205.

Complainants' expert, Barnes, also sums up his views in the following brief sentence (*Rec.*, p. 373):

"The restricted passage 35, of complainants' valve, and the restricted passage e, of defendants' 1889 valve, and B, of defendants' 1891 valve, are identical in purpose and function."

Mr. Barnes' reasons for so testifying are given at length at *Record*, pages 372, 373.

Also, in confirmation of the correctness of his conclusions, Mr. Barnes subjected them to actual test.

Barnes, Rec., p. 386, fol. 599 (*d*).

As to the partition 9 of defendants' valve, Mr. Newbury states accurately and fully its relationship to the other operative parts of the mechanism.

Newbury, Rec., pp. 158-160, Qs. 200-202.

Mr. Newbury's cross-examination herein is lengthy and extensive (Rec., pp. 206-235, x-Qs. 236-288).

And that "momentary differential pressures" have actually been used in the Westinghouse valve for many years, and, in fact, that they were employed in the automatic triples, see H. H. Westinghouse (Rec., p. 287, Q. 417), where, in replying to defendants' expert, Arch, he says:

"It is evident that Mr. Church's lack of practical experience has misled him to fail to observe that the principle of momentary differential pressures is not new, and that it is not embodied for the first time in defendants' structures.

"All practically operative triple valves, whether of the kind used prior to 1887 or those subsequently devised, perform their functions properly when momentary differential pressures are created by the means of restricted passages.

"The presence of restricted passages, for the purpose of creating momentary differential pressures, is required for the same purpose in the defendants' structures as in that shown in Patent 360,000, and it does not exist in any different degree in any of these structures."

We submit with the utmost confidence that these proofs fully refute Mr. Boyden's contention that he is the inventor of that which defendants contend is the distinctive feature of their valve, and also show that these features of "momentary differential pressures" required by "a restricted port B" should be credited to Westinghouse, along with the other essential features of novelty and utility which are admitted and everywhere adjudicated to be his.

And, this being so, Boyden's merits as an inventor drop out of the case. All he has done is to take the essential elements of the Westinghouse quick-action invention, embody them in somewhat different but equivalent forms and relationships, but retaining every substantial feature or element of construction, function and operation.

Removing Partition 9.

Great stress is laid by defendants on what happens, upon the removal of the partition 9. When there is no partition, there is only a *single, unobstructed and large* passage for the flow

of auxiliary reservoir air into the passageway, which *should* conduct train-pipe air to the brake cylinder, in order to cause "quick action." But, under *that* condition of things (as Westinghouse had already shown), there can be *no* "quick action," as train-pipe air cannot flow into a passageway already filled with air at a higher pressure. The two passages may, at some place, join, but must be *so far* separated that the flow of auxiliary reservoir air shall not prevent the flow of train-pipe air, when "quick action" is required. Partition 9, with its restricted port B, accomplishes this. The principal thing which happens, in removing partition 9, is that the removal of the partition necessarily involves the removal of the restricted port B. The partition 9 is of no importance in the case, nor in the device, except as it contains the restricted port B. And this restricted port, as one of the incidents of quick action, has been taken and appropriated by defendants, along with the main invention. As we have clearly shown, they were seriously in error in claiming that it belongs to them.

Boyden's 1883 Patent, No. 280,285.

As this patent figures more or less in the testimony, it should perhaps have a few words of comment.

1st. It is not pretended that it contains, either in form or in substance, the quick-action invention here in controversy. Boyden, himself, says of it (Rec., p. 497, Q. 8):

"I wish to state here that my 1883 patent was not for a 'quick-action' valve (as that term is now understood)."

Again (Rec., p. 574, x-Q. 195), he admits the following to be correct, *italics* and all.

"In the triple valve of patent 280,285, *no application whatever* of the brakes is effected by the passage of main air-pipe air to the brake cylinder, and no main air-pipe air is admitted to the brake cylinder until *after* the brakes have been applied with the maximum rapidity and force within the capacity of the device *by auxiliary reservoir air alone.*"

And again in the same answer he says :

" I did not wish to imply, nor do I now, that my 1883 patent is for a quick-action valve such as you have stated."

And the patent itself is in accord with these admissions. Thus the specification sets forth (Rec., p. 776), as the first and main object of the invention (the italics being our own) :

" *To provide for replenishing, while the brake is on, the air reservoir on each car or the brake cylinder, when the pressure therein has been lessened by leakage.*"

Judge MORRIS' decision followed the lines thus indicated, with the result of finding (Rec., p. 849), that, as between the Boyden patent of 1883 and the Westinghouse Patent No. 360,070, "*there seems to be no analogy or comparison which can be made between them.*" Hence, this Boyden Patent of 1883 was ruled out, as of no effect in the case.

No exception was taken to this ruling, and the Court of Appeals did not even refer to this patent.

Hence, we presume that it may be disregarded, except as to three facts.

FIRST: THE DISCLAIMER.

In order to draw clearly the distinction between what was old and what was new, Westinghouse was required to disclaim in his specification this Boyden 1883 device. He did so. It is then argued that this disclaimer operates as a limitation, not as to something which, being old, he *could not* claim, but as to something which, *being his*, he *has claimed*.

Non sequitur. He merely disclaimed a device or mechanism which was prior in date, but which had no substantial identity with the invention of his. He disclaimed, not a part of his invention, but *something else*. Boyden says three times, under oath, that it is *something else*. The patent itself says that it is *something else*. Judge MORRIS says, judicially, that it is *something else*. Defendants, by not excepting, practically admit that it is *something else*. Hence, in disclaiming it was a nugatory act, which did no good and no hurt.

If A and B are different things, the owner of B does not, by disclaiming A, limit at all his right to B, and to everything that appertains to B.

SECOND : THE CHECK-VALVE DEFENSE.

Mr. Boyden, when on the stand, also tried to make it appear that he was the first to put a check valve in the passageway or port leading from a train pipe to a triple-valve chamber—that is, his check valve 26; that such a check valve was contained in his patent of 1883, No. 280,285, and was transferred to defendant's present valve (Rec., p. 497, Q. 8).

The evident purpose of this was to acquire some credit to himself as an independent inventor.

We prove, in reply, that he did not invent this any more than he invented the restricted port. It is found in two U. S. Patents of 1875, and in an English Patent of 1879—long prior to Boyden's 1883 Patent.

Newbury, Rec., p. 160, Q. 203.

THIRD : ANOTHER ALLEGED BOYDEN INVENTION.

Mr. Boyden also tries, in the same connection, to get some credit out of the alleged fact that he showed in his old 1883 patent "a single valve H arranged to govern a port through which the air pressure from the main air pipe and the air pressure from the auxiliary reservoir both pass to the brake cylinder" (Rec., p. 497, Q. 8).

As we have already seen, he did this in his 1883 patent merely *to replenish loss by leakage; not to apply the brakes*. That was already done, and done just as in the old automatic brake. Through the *same passages and ports* which were used in applying the brakes, Boyden proposed to replenish loss by leakage.

As Boyden has three times admitted that this did not involve quick action, we need not discuss *that* question further. But as to the "*something else*" which he says, or at least implies, was his, we show that it, too, was older in the art than 1883. It is found in English Patent No. 3000 of 1879 (Rec., p. 163, fol. 246).

It is hence submitted :

1st. That as an inventor of any *substantive matter of invention*, whereby the Boyden valve is, *as to its essential elements*, differentiated from the Westinghouse, Mr. Boyden has no standing whatever. That feature on which he bases his chiefest claim, "the Restricted Port B" in "the Partition 9," whereby to secure "Momentarily Differential Pressures," all this was taken bodily from Westinghouse.

2d. That as regards any claim of credit to himself on account of any substantial addition made by himself to the art prior to 360,070, Mr. Boyden has just as little standing as before. Hence :

3d. That as regards defendants' present infringing valve, Boyden is not entitled to rank any higher than that of a subsequent improver, in mere details, of a pioneer invention of unimpeachable novelty and immeasurable utility.

"Substantially as Described."

In our assignments of error filed with our petition for a writ of certiorari, we submitted the following :

"FOURTH. And as matter of error and variance herein, your petitioners respectfully represent that the force and meaning of the phrase 'substantially as set forth,' as explained and applied by the said Circuit Court of Appeals for the Fourth Circuit, is directly at variance with the decisions of this Court, and is in error as matter of law."

The Court of Appeals, in the opinion rendered by Judge HUGHES, defined what is meant by "substantially as described" (Rec., p. 877, last two lines, and top of p. 878).

This Court, in *Lake Shore Co. vs. National Co.*, 110 U. S., 229, 235, defined the meaning of this and other like phrases, and the definition then given is, as we understand, generally recognized by the profession as still authoritative and binding. It runs thus—the italics being our own :

"the words 'substantially as specified' mean substantially as specified *in regard to the combination* which is the subject of the claim."

Nor was this an *obiter dictum*. The issue of infringement turned upon the meaning and force of these words.

This decision was cited in the Court of Appeals in the argument of this same issue in the case at bar. That Court disregarded the rule or definition thus cited, and held, as we understand their decision, that "substantially as described" relates not to *the combination* which is the subject of the claim, but to the *separate or individual elements* which make up the combination.

And this variance is material and important in that the decision as thus made by the Court of Appeals, as a Court of last resort, may be regarded as final and authoritative in the Circuit Court of that and possibly other Circuits.

It is believed that the error thus made should be corrected by an affirmance of the rule formulated in *Lake Shore & M. S. Co. vs. National Co.*, *supra*, or in such other manner as may seem good to the Court.

The Westinghouse Patent 217,838.

A copy of this patent will be found at record, page 759.

It is not claimed anywhere in the proofs, or elsewhere, so far as we know, that this patent contains or anticipates the invention here in suit.

Judge MORRIS says of it (Rec., p. 847):

"It is true that, in searching for some device which would give quick action, Westinghouse had, before the date of the patent in suit, conceived the idea that it might be accomplished by venting the train pipe at intervals along the train. He had tried having two or three vents at intervals in the length of the train controlled by electrical apparatus, and also had tried relief valves placed in the pipe coupling of each car which would open to the atmosphere and vent the train pipe quickly in case of accident or other sudden release of pressure in the forward part of the train. This was shown in the Westinghouse Patent No. 217,838, July 22, 1879, but neither of these attempts were successfully applied, and *they did not solve the problem of quick action.*

"*The problem was not solved; indeed, the first step in the direction of solving it does not appear to have been taken until the experiments which led to the Westinghouse patent now in suit.*"

As defendants took no exception to this ruling of Judge MORRIS, it may be inferred that they are satisfied with its correctness.

The principal effect of this Patent 217,838 is in that it tends to show that as early as 1879 Mr. Westinghouse *tried* to make a quick-action brake, but at that time he did not know how.

The result was that he made a mechanism which was inoperative and worthless for any practical use, except as it told all subsequent inventors that *that way had been tried and had failed* (Newbury, Rec. p. 189, Q. 223; Barnes, p. 405, Q. 699).

Really, this issue of inoperativeness was of doubtful relevancy, under the pleadings. As already stated, this device of patent 217,838, did not contain the invention in question, and nobody had said that it did; but as defendants' experts had tried to give it some prominence as a part of the state of the art, we considered it a sufficient reply to prove its inoperativeness.

Defendants, by special leave of Court, undertook to reproduce the apparatus of this patent, and by testing it to show that it would work. Mr. Boyden testified as to these tests, and finally, on cross-examination, he admitted that:

"The results produced by the devices of patent 217,838, *as I tried them*, are not of an efficiency that would justify me in recommending the use of the devices to railroad officials." (Rec. p. 692, X Q. 346).

In the next following answer, speaking of the same apparatus, he says that it "was not practically operative to be used in service."

And when pressed for his opinion, in the question next following, he says:

"My opinion is that the device *as I used it* would not be acceptable to railroad officials for practical use."

While it is hardly necessary to reply to such testimony as this, we proceeded, perhaps out of excess of caution, to prove, in reply, (1) that Boyden, in his efforts to make the apparatus work, had departed from the instructions of the patent; (2) that he had done this without any warrant whatever; (3) that the change or departure which he had made, destroyed the *intended* operation of the device—that is, that the apparatus as he changed it, would *not* operate in the manner described in the patent, and (4) that what

little success he did attain in making his apparatus work, was due to the *unauthorized change* which he made in its structure.

This, as well as Boyden's admissions, quoted above, amply confirm what we said at first—that it is an inoperative mechanism.

The replying testimony of Westinghouse is not lengthy, and fully sustains the four points last above stated (Rec., p. 829 *et seq.*).

Sundry Theories of Defendants' Experts.

It would unduly lengthen the present brief, were we to follow in detail *all* the erroneous or misleading distinctions which defendants' experts elaborate at greater or less length. Nor is it thought to be necessary, in view of what is believed to be the controlling character of the considerations already presented. But we may properly note them, lest it be thought that we have no reply.

1. Effort is made, through page after page, to distinguish the Boyden quick-action valve 22 from the Westinghouse quick-action valve 41, for the reason that the latter valve is a "*separate*" valve from the valve 14, which primarily governs the flow of *auxiliary reservoir* air to the brake cylinder.

This is wholly a fallacious distinction. The Boyden valve 22 is a "*separate*" valve from the Boyden stem slide valve *i, k, j*.

The feature of "*separateness*" of construction and operation, is mechanically and functionally as fully present in one as in the other.

2. It is also said that the Westinghouse quick-action valve 41 is an "*added*" valve—that is to say, that it was added to the triple mechanism of 220,556, in the making of the invention in suit.

This is at least an effort at a *misleading* distinction.

Defendants allege that their quick-action valve 22 is a modification of another old Westinghouse triple valve—that of Patent No. 141,685—a modification of the plug valve *o*. We have already, with some fullness, discussed this theory of theirs, but a word or two more may be in place.

Assuming that what they say in this respect is true—that they

did modify 141,685, and that they modified it along the lines which they now point out, *how did they do it?*

We contend that they are in error in their understanding of the modifications which they say that they made, and we have endeavored *supra* to show the facts in their true aspect. But we will now assume—but only for the sake of argument—that the Boyden valve 22 is a modification of the plug valve *o* of 141,685.

How, upon that assumption, was it modified?

It will be seen that the plug valve *o* of 141,685 is rigidly connected by an intermediate stem with the diaphragm which moves it. Boyden, in making his alleged modifications, after changing its form from a “*plug*” to a “*poppet*” valve, *detached it from its stem*, so that it was no longer rigidly connected thereto as before, but could remain in place during the “*preliminary traverse*” of the piston and stem.

This loosening of the valve from the immediate control of its stem *made another valve of it*. It acquired by such change and modification a new capacity and function. It was no longer the same valve either in structure or in operation. In both respects it was materially altered. It was a “*main*” valve *before* the change; it was a “*quick-action*” valve *after* the change.

The change being made, Boyden had next to provide a “*main valve*.” Hence, the stem hole *i, j, k* was bored and the sliding stem became the main valve.

Hence, defendants’ contention amounts simply to this:

Westinghouse had a “*main*” valve, which, algebraically, we will call *a*, and which in its perfected form (220,556) answered his purpose.

He invented and, as defendants contend, “*added*” thereto a “*quick-action*” valve, which, algebraically, we will call *x*, as it was previously unknown.

Boyden took an older form of the known “*main*” valve *a* (141,685), modified and changed it till he had put into it the essential features of novelty and utility which belonged to the new quick-action valve *x*, and then “*added*” another “*main*” valve *a* in lieu of the “*main*” valve which he lost by making the change.

Both triple valves contain $a+x$, as the final result of the working out of the equation. Hence there is no substantial difference due to the way in which either was produced.

3. The analysis of "valve functions," which is made at great length by Boyden and Church in the first part of the testimony of each, in connection with the conclusions which they seek to draw therefrom, is fallacious and misleading, and is so, chiefly because:

It is based on an error of observation and of fact in the working of valve 22. Boyden and Church both failed to note or observe the fact that valve 22 never opened in ordinary *service* use, until *after* the *air-charging* work of ordinary service was substantially completed. The facts herein (Barnes, Rec. p. 391) have already been discussed (*supra*, p. 42 *et seq.*). Hence, it will be seen that Boyden and Church fell into the error of attributing to the Boyden valve 22 a "main-valve" function which the facts clearly show that it does not possess. (Newbury, Rec. p. 168, Q. 210.)

If the Court desires to go into this matter further, the facts bearing thereon are presented in the record without undue prolixity. (Newbury, Rec. p. 176, Q. 217; Barnes, Rec. pp. 355-358, Q. 660-662.)

4. Defendants refer with much apparent emphasis, to the passage 46, which Mr. Westinghouse made in the walls of his valve case, as a port for the direct flow of air, in the quick-action operation, from the train pipe to the brake cylinder. In the Boyden device, this line of flow is through an enlarged port or passageway F, made for the purpose, in the triple-valve piston 29. Effort is made to find herein a material difference.

We have already discussed this question at probably sufficient length, when considering the issue of infringement. We refer to it again only to say that an air port through the centre of the triple-valve piston, is found in the Westinghouse triple-valve patent, No. 172,064, where it is designated by the letter *s* (Rec., p. 757).

Hence in changing the direct passage way in question from the walls of the casing to the centre of the piston, defendants have not merely taken an *old and well-known substitute*, but they have taken

substitute which *Westinghouse* invented. And then, they pretend that it is theirs, and not his.

5. Because *emergencies* always existed in the running of railway trains, and because the application of brakes, in *emergencies*, has long been well-known, therefore, defendants argue that an *emergency brake* was not a new thing in the art, at the date of the invention here in question.

This involves merely an effort, by applying an *old* name to a *new* thing, to suggest that the *new* thing is *not* new.

Old brakes were applied in emergencies, but there was no brake known in the art as an *emergency brake*, until the introduction of the Westinghouse Quick Action or Emergency Brake. Emergencies in the running of trains were known; emergency applications of old brakes were also known; but an *emergency brake* was *not* known. *That thing* was first invented and patented by Mr. Westinghouse, in and by the letters patent here in suit.

It is submitted that the case should be remanded, with directions that a decree be entered for complainants.

THE WESTINGHOUSE AIR-BRAKE
COMPANY,

vs.

In Equity,
No. 5969.

THE NEW YORK AIR-BRAKE COM-
PANY, ET AL.

This case, which comes up for hearing upon pleadings and proofs, is a suit in equity to enjoin infringement of certain Letters Patent of the United States. These patents are three in number, viz.: No. 360,070, to George Westinghouse, Jr., March 29, 1887, for "Fluid-Pressure Automatic-Brake Mechanism," complainant alleging infringement of claims 1 to 5 inclusive; No. 376,837, to George Westinghouse, Jr., January 24, 1888, for "Fluid-Pressure Automatic-Brake Mechanism," complainant alleging infringement of claims 1, 3 and 4, and No. 393,784, to Harvey S. Park, December 4, 1888, complainant alleging infringement of claims 1, 3, 4, 5, 7, 8, 9, 10, 12, 13, 14, 15 and 16.

LACOMBE, Circuit Judge :

Judicial opinion, as to the validity and construction of these three patents, has been so fully expressed in the various decisions already rendered, and which are referred to below, that no extended disquisition is either necessary or proper in this Court. Reference may be had to the opinions cited, for a statement of the reasons

which have induced the conclusions hereinafter briefly indicated.

Suit was brought in this Court upon 376,837 and the Park Patent, and came on for hearing before Judge TOWNSEND, who sustained the validity of both patents, found infringement of 376,837, and non-infringement of the Park Patent (*Westinghouse vs. New York Air-Brake Co.*, 59 Fed. Rep., 581, Nov. 20, 1893). This suit was appealed to the Circuit Court of Appeals in the Second Circuit, and Judge TOWNSEND's decision as to these two patents was affirmed (*Westinghouse vs. New York Air-Brake Co.*, 63 Fed. Rep., 962, Oct. 15, 1894). Defendants modified their device, and the suit at bar was brought to enjoin the sale or use of their new "Quick-Action Triple Valve B." Application was made, upon elaborate affidavits, for a preliminary injunction, the motion was argued at great length, was duly considered by this Court, and an opinion filed December 24, 1894, sustaining the validity of No. 360,070 (which has not been in issue in the earlier suit), and finding infringement of claims 1, 2 and 4 of that patent, and also of claim 1, of 376,837 (*Westinghouse vs. New York Air-Brake Co.*, 65 Fed. Rep., 99). Suit was also brought in the Circuit Court for the District of Maryland, on No. 360,070, to enjoin still a different form of mechanism, and the cause coming on before Judge MORRIS, March 11, 1895, he held claims 1, 2 and 4 to be valid, and found infringement of claim 2, but not of claims 1 or 4 (*Westinghouse vs. Boyden Power-Brake Co.*, 66 Fed. Rep., 997). An appeal from the preliminary injunction, issued in the suit at bar, came up for hearing before the Circuit Court of Appeals in the Second Circuit, and was decided May 28, 1895. The decision sustained the Circuit Court, as to Patent 360,070, but reversed as to 376,837, on the sole ground that the question was "too doubtful to be resolved in favor of the complainant upon a motion for a preliminary injunction, and should be reserved for disposition upon the final hearing of the cause" (*Westinghouse vs. New York Air Brake Co.*, 69 Fed. Rep., 715). An appeal

from Judge MORRIS' decision was subsequently decided by the Circuit Court of Appeals, Fourth Circuit, November 11, 1895. That Court sustained him as to claims 1 and 4 of 360,070, but reversed as to claim 2, holding that it is fatally defective in claiming only a result, and not identifying the specific means by which that result is achieved (*Westinghouse vs. Boyden Power-Brake Co.*, 70 Fed. Rep., 816).

In the light of these decisions, the questions now presented are to be disposed of.

PATENT No. 360,070.

Claims 1, 2 and 4 were sustained by this Court, on motion for preliminary injunction, and infringement found. The Court of Appeals in this Circuit has sustained that decision, in these words: "We agree with the Court below that the defendants' apparatus is an infringement of the first, second and fourth claims of Patent No. 360,070, and deem it unnecessary to add anything to the opinion." In the record now presented at final hearing, there is nothing which calls for any modification of the opinion already expressed. To enter into any extended discussion of the case, as to this patent, would be a work of supererogation, inasmuch as the case in the Fourth Circuit, above cited, has been taken by *certiorari* to the Supreme Court, and, because of the existing difference of opinion between the Courts of Appeal in the two Circuits, has been advanced on the calendar so that it will be submitted to that tribunal, for final disposition, within the current month. The fifth claim of this patent was not passed upon, on the motion. It differs from the fourth, only in adding a check valve to the combination of that claim; it is not disputed that defendants' device contains a check valve, and, if it be held to infringe the fourth claim, it infringes the fifth as well. The third claim contains, as an element, "a second admission of air from the auxiliary reservoir to the brake cylinder." Manifestly, this is a narrower claim than those discussed when the case was here before, and, since the patentee has chosen to make a

"second admission of air" material, infringement is not found in a device which substitutes a "single admission of air," although such *single* admission be continuous.

PATENT No. 376,837.

In reversing the former finding of this Court, as to the first claim of this patent, the Court of Appeals did not pass upon the merits. It held only that the question was too doubtful to be resolved, upon motion for a preliminary injunction, but should be reserved for final hearing, upon a complete record, where abundant opportunity has been given to reply to testimony, expert or other, and to cross-examine all witnesses. An examination of the record, as it now stands, has not changed the conclusions of this Court, as heretofore expressed, and it is therefore unnecessary to do more than refer to the former opinion, as stating the reasons for holding the first claim to be infringed.

The third and fourth claims have not been passed upon by this Court, and were not presented to the Court of Appeals. Both of them contain, as an element of the combination, "a passage establishing communication between said supplemental piston and an auxiliary reservoir." The complainants contend that this passage is to be found in defendants' port "*p*." Inasmuch as this Court finds "an auxiliary reservoir" in the space which is contained in the chamber *P* above the piston, and in the port or passage *p*, below the cut-off 14 in the sliding valve, it is manifest that there is no "passage establishing communication" between the supplemental piston and such "reservoir." If this Court is right in holding that the space referred to is "an auxiliary reservoir," then it abuts directly on the supplemental piston, and any "passage" between the two is dispensed with. For this reason it is thought that the third and fourth claims of No. 376,837 are not infringed.

PARK PATENT No. 393,784.

The Court of Appeals in this Circuit has held that this is a subordinate patent, and must receive a narrow construction. The feature which Park introduced into the quick-action operation, was the working of the emergency valve piston by *train-pipe pressure*. This specification states that the object of the invention is "to enable a better, quicker and more certain action to be had of pneumatic controlling devices for air brakes, * * * and, *at the same time*, have the valve, controlling the direct passage of the pressure from the train-pipe to the brake-cylinder, *under the direct action of the train pipe pressure*." In describing the operation of his device, the patentee says: "the train-pipe pressure through the pipe Z will act on the under side of the valve S, opening the valve: &c."; and, also, "It will be thus seen that the valve S is controlled on both opening and closing by the train-pipe pressure, * * * and, with this construction, the train-pipe pressure performs the office of both opening and closing the valve." Many of the claims contain words describing the valve, or the valve and passages, as "actuated by train-pipe pressure," or "controlling the pressure to the brake cylinder direct by train-pipe pressure," or some equivalent phrase. Other claims there are, which contain no such phrase; but, since Park's invention was a device for working the emergency valve piston by train-pipe pressure, the complainant's expert is entirely correct in the statement, that "all (the claims) refer to combinations of parts, which relate to the various structural features of a triple valve, in which the extra traverse of the pistons so adjusts the parts, that the valve between the train pipe and the brake-cylinder can be *opened by the compressed air in the said train pipe*. * * * The improvement that Park introduced in the art, and has described in his patent, only threw upon the main piston the extra labor of compressing the spring H; the valve S, being a poppet valve, did not have to be slidden over its seat, while under pressure, by the movement of the

piston, but *was raised by the air pressure in the train pipe*. This is thought to be an improvement * * * minor improvement of the Westinghouse Patent. * * * Thus, it will be seen that all the claims of the Park Patent relate to that improvement."

The conclusions expressed in the former opinion of this Court, when granting the preliminary injunction, and which are still adhered to, as to the relations between the defendants' valve and the first claim of Patent 376,837, dispose of the contention that such valve infringes the Park Patent. All compressed air, in any part of the entire brake system behind the engine, is, or has been, train-pipe air. It is compressed in the main reservoir on the locomotive and, thence, passes into the train pipe proper, and from that train pipe into its several branches and such chambers, connected therewith, as may admit of its entry. All agree that, while it is still in the train pipe, the force it exerts is "train-pipe pressure." All agree that when train-pipe air has passed through the charging port into the auxiliary reservoir of the original triple-valve device, or its subsequent modifications, the force it exerts is "auxiliary reservoir pressure." This Court has found, further, on complainant's contention, and against defendants' opposition, that, when train-pipe air has passed through some other port or passage into another chamber, and has been confined therein, and cut off from further connection with the source of supply, the force which it exerts is "pressure from an auxiliary reservoir," and, because of such finding, has held defendants' valve to be an infringement of Patent 376,837. If this finding be correct, defendants' valve does not infringe the Park Patent, because, in that patent, the compressed air, whose expansive force lifts the piston, is within a chamber in free communication with the train pipe; it has not yet passed beyond any barrier which segregates it from the whole body of train-pipe air, and its force may fairly be called train-pipe pressure; while, in the defendants' valve, the compressed air, by the dissipation of whose expansive force the piston is induced to move, is within a cham-

ber which has been absolutely cut off (by the slide 14) from the train pipe; it has been segregated from the general body of train-pipe air, into an independent reservoir, and its force may fairly be called "pressure from an auxiliary reservoir." For these reasons, it is thought that defendants' "Quick-Action Triple Valve B," the device complained of, does not infringe the Park Patent.

A decree will be entered, in accordance with the views above expressed.

BOYDEN POWER BRAKE COMPANY, ET AL.

SUPPLEMENTAL BRIEF FOR WESTING- HOUSE AND WESTINGHOUSE COM- PANY.

A re-argument of the above appeals having been ordered by this Court, it seems proper that a few supplemental suggestions should be adverted to, which were called to our attention by the former argument.

These will be briefly dealt with, under separate headings.

I.

Importance of the invention before the Court.

Whatever may be asserted (erroneously as we hope to show), as to the defectiveness *in form* of any claim in the patent in suit, it is impossible to deny the commanding importance of the invention which underlies the patent, and which it purports to describe and claim.

The briefs and arguments of the Boyden counsel emphasize this fact.

Less than ten years ago, air or power brakes could not be utilized for the quick stoppage of long freight trains, and, as freight trains were almost invariably long, such brakes could not be so used on freight trains at all.

The highest type of power brake which existed prior to 1886 was radically defective.

Mr. Hill states this, and the reason for it, with great clearness and precision, in his brief (p. 12) :

“ TRIPLE VALVE DEFECTIVE ON LONG TRAINS.”

“ The triple valve, thus slowly evolved from the original form of Patent No. 141,685, August 12, 1873, to the highly improved form of Patent No. 220,556, October 14, 1879, and in the latter form used by the complainants without further material improvement till the year 1888, was satisfactory for short trains consisting of eight or ten cars or less, but on long trains consisting of forty or fifty cars or more, it was not only unsatisfactory, but absolutely impracticable ; and its *impracticability resulted from the very fact that the piston had the two traverses* referred to by Mr. H. H. Westinghouse at the bottom of p. 123, namely, a partial traverse for graduating purposes, and a full traverse for emergency stops”. (Italics are Mr. Hill's.)

Mr. Westinghouse, by the remarkable invention in suit, converted the very cause of difficulty into an element of success.

While a triple valve, with a piston having the capacity for “ two traverses,” was, *by reason of that very fact*, incapable of use

in emergencies on long trains, *because*, having a piston with a double traverse, it admitted air only from an auxiliary reservoir, Mr. Westinghouse, by using the second or "further traverse" to admit "*train-pipe*" air, caused the very defect of the prior structure to be a means of reaching the *new result*.

Such triumphs in mechanics are only achieved by those whose genius is of that supreme quality which enables a commander to snatch victory from defeat.

Speaking of the *second* claim,* Judge MORRIS said (R., p. 848):

"The *gist* of that invention is the use of the further traverse of the triple-valve piston to open a *valve which admits air directly from the train pipe to the brake cylinder, with the result that the train pipe is vented, and the train-pipe air utilized.*"

It is a conceded fact that no prior mechanism comprised these features, or ever accomplished this result, *in any way whatsoever*.

By the invention in suit, air brakes on freight trains first became a possibility, and have now become a necessity of national importance.

Three times, since the announcement of Mr. Westinghouse's achievement, the President of the United States, in his annual message to Congress, has called for the enactment of laws requiring railroads engaged in interstate commerce to equip themselves with such brakes (and with automatic couplers), "in order to greatly reduce the present fearful death rate among railroad employees" (President's Message of 1890).

Prior to Mr. Westinghouse's invention, it is conceded that no device existed which could have been made the basis of such legislation.

*As shown in our prior brief (pp. 29, 30), the first and fourth claims are shown to not require a double traverse of a *single* piston, but to be based upon another feature, viz., that there shall be *two valves*, one ("the main valve") to admit air from the reservoir for service work, and the other, an "auxiliary" valve, to admit train-pipe air for emergency work.

Congress has now made the use of such brakes, on Interstate roads, imperative (Act of 1893, Ch. 196), and many of the States have legislated to the same effect, as to railroads within their limits (Rec., p. 135, see p. 202). Mr. Westinghouse, speaking in 1891, said (Rec., p. 132) :

" Previous to the Burlington Trials, the subject of legislation having in view the compulsory use of power brakes upon freight trains, on account of humanitarian considerations, was seriously considered, *but the absence of practical devices rendered legislation on this subject impossible.*

" Since the introduction of the *quick-action brake*, several of the State legislatures have enacted laws making the use of power brakes on freight trains compulsory ; and the National Legislature has had the subject before them for consideration." (Italics ours.)

The "Quick Action" brake has also demonstrated its greater efficiency, even on passenger trains, and is rapidly superseding older forms. Passenger trains, by its aid, can be stopped " in a distance from 25 % to 40 % less with the quick " action brakes than when the prior automatic system was " used " (Rec., p. 132-3).

Rarely has an invention, which complies so completely with the reason and policy of the Patent Laws, been before a Court asking for protection ; and never, we think, has an invention been more conspicuously deserving of every permissible construction to give it such a liberal scope as will " prevent the " real substance of the invention from being bodily appropriated by an infringer " (110 U. S., 229).

See principal brief, p. 31.

II.

The experiments with air-brake apparatus in the presence of the Court.

At the last hearing, the Boyden Company exhibited and operated some air-brake apparatus in Court, from which they urged that certain conclusions were to be drawn.

FIRST. That the Boyden structure could be operated when the ring or partition 9 was removed, so as to admit auxiliary-reservoir air to the brake cylinder, both intermittently (which they called "graduating"), and rapidly, for a fuller application; and that in both of these methods of operating the valve—intermittently and rapidly—nothing but auxiliary-reservoir air would enter the brake cylinder; and that then, by merely inserting the ring or partition 9, the structure was changed to a "quick-action" apparatus, which, when operated intermittently or slowly, would admit auxiliary-reservoir air only, for graduating and service work; but which, if operated suddenly, would admit train-pipe air to the brake cylinder for emergency use.

From this exhibition it was argued that the Boyden "quick-action" structure must be essentially different from the Westinghouse structure, and its operation due to substantially different causes.

Tersely put (see Mr. Hill's brief, pp. 40, 41), the Boyden valve was alleged to be *nothing* but an "old-fashioned triple valve," which became a "quick-action" valve, not by any structural change, but because it then operated "simply by *differential pressures*."

This conclusion was claimed to be deduced from the fact that the mere insertion into the structure of the ring, or partition 9, with its restricted aperture B (a part which does not move) changed it from one type of valve—the "old-fashioned triple," admitting only reservoir air—into another type of valve—the "quick-action" triple, admitting train-pipe air.

No such conclusions can be drawn from the experiment.

(a) No such a structure as a Boyden valve *without its partition* has ever been used *in practice*, for any purpose. Experiments in court, with a structure which no one uses or wants to use, are of little value or relevance.

(b) The structure exhibited in court as a Boyden structure, and without the partition 9, was *not simply* an "old-fashioned triple," but was a triple valve having *two valves*, one capable of *being opened independently* of the other. These valves are the stem valve (*i, j, k*) and the surrounding poppet or plug valve (22). Each is capable of *independent movement* to open its own port, one by the "preliminary" and the other by the "further" traverse of a triple-valve piston.

No such double-valved form of triple was known in the prior art.

The structure of Westinghouse Patent No. 141,685 (p. 736), has only a *single main valve*.

So has that of Jones' Patent No. 166,386 (p. 745).

So also with Perine Patent No. 166,405 (p. 749).

So also with Westinghouse Patent No. 168,359 (p. 752).

So also with Westinghouse Patent No. 172,064 (p. 757).

So also with Boyden Patent No. 280,285 (p. 776).

The structure of Patent No. 220,556 is alone relied upon by the defendants as exhibiting a structure having two valves. But it is *not really* a structure of the same kind as Boyden's, as is fully shown in our principal brief (pp. 72-79).

The two valves shown in Patent No. 220,556 cannot initially be made to *open independently of each other*. The main slide valve H (to which the defendants now erroneously say their valve 22 is equivalent) *always* opens, and on the *first* traverse of the piston. The interior poppet valve moves *with* it, and opens its port only to connect with one *necessarily opened by the* "main valve H." After once opening *both* valves, the sensitive poppet valve may then be *retracted* and made to *close* its port, and, incidentally, the port uncovered by the main

Valve of Patent 168,359.

Valve of Patent 220,556.

Valve of Boyden Structure.

valve, without retracting the main valve. No such action, *nor anything really resembling it*, is found in defendants' structure.

Boyden's valve, *i, j, k*, opens on the *preliminary* stroke of the piston, *without moving valve 22*; and when valve 22 is opened by a "further" traverse of the piston (which is the only way of opening it), *its* port cannot be closed by merely closing the port of valve *i, j, k*.

The two valves of defendants' structure are *both* capable of admitting *auxiliary reservoir air only*, to the brake cylinder, when the partition 9 is absent, because, in the structure as thus organized, there are no such air passages as to make it possible for *any* movement of the triple-valve piston to result in the opening of any port by which *train-pipe* air could be admitted to the brake cylinder.

The structure of Boyden exhibited in court (when unprovided with the partition 9) is, it is true, made to *look* like one form of the "old-fashioned triple" (Patent 141,685); but it differs from it, *and from every other such triple valve*, in this substantial respect, that it contains two *separately opening* valves; one (*i, j, k*) opening, *without moving the other*, only by a "preliminary" stroke of the triple-valve piston, and the other (valve 22) opening, *independently* of the first, *only* by the *extreme* or "further" stroke of the triple-valve piston. The latter valve (*viz.*, valve 22) is so located and arranged, with reference to the rest of the structure, that, *by partitioning the air passages* (by inserting the partition 9), it is brought into such relation with those passages that, by the "further" movement of the triple-valve piston, it will admit *train-pipe* air directly to the brake cylinder.

The accompanying diagrams show clearly how *unlike* to an "old-fashioned triple", such as that of Patent No. 168,359 (which is typical of the prior art) or of Patent No. 220,556, is the Boyden *two-valve* structure.

Diagram I. shows the "release" position of all three valves. Brakes are "off."

Diagram II. contrasts the effect of a "preliminary" traverse of the piston for a graduated application, in all three cases.

In Patent 168,359, there is only one main valve, and it has opened its port to the brake cylinder, *partially*.

In 220,556, *both* valves have moved and the ports through *both* of them are opened; but *partially* only, as regards the slide-valve port.

In Boyden's, *only* the sliding-stem valve *i, j, k* has opened.

It has opened *partially*, and its action is precisely like that of the *single* valve in No. 168,359, and that of the *main slide valve* of No. 220,556.

The characteristic function of the main valve, by which, entirely regardless of the form or shape of the valve, it has always been distinguished in the art, is to open, partially or fully, and to again close the port controlling the flow of air from the auxiliary reservoir to the brake cylinder. It will be observed, in Diagram II., that the main slide valve of each patent, 168,359 and 220,556, has been moved for this purpose, and that the corresponding valve in the Boyden structure is the stem valve (*i, j, k*).*

There is nothing, in this operation of Boyden's valve, corresponding to the movement of the two valves of No. 220,556, for in No. 220,556 it is a necessity that *both* valves shall move (upon either "preliminary" or full traverse of the piston) to effect *any* opening of the "main-valve" port.

* The valve that performs the functions which distinguish it in the art as the *main* valve, is, in each structure (as in our former brief), colored *black*; and the supplementary valve, which performs the *port-closing* function of the main valve of Patent 220,556, is colored *yellow*.

In these diagrams, only the valves and their ports are shown, the other portions of the structures having been, for greater clearness, cut away and omitted.

Diagram II.—Showing Main Valve in a Position for making a “Graduated” Application of the Brakes.

Valve of Boyden Structure.

Diagram III.—Showing Main Valve in the Position for Stopping the Flow of Air to the Brake Cylinder, after making a Graduated Application of the Brakes.

Valve of Patent 168,359.

Valve of Patent 220,556.

Valve of Boyden Structure.

Diagram III. illustrates the function of the poppet valve of 220,556; viz., it can be made to *close* and shut off the flow of auxiliary-reservoir air without shifting the main slide valve. It can, therefore, shut off the flow of air, *even* though the slide valve may *stick* and *remain open*.

Nothing corresponding to this auxiliary method of closing the main-valve port in Patent 220,556 can be found in the Boyden structure.

The stem valve (*i, j, k*) of the Boyden structure, which *alone* [moved to open the port to the brake cylinder, has, in Diagram III., *alone* performed the main-valve function of closing the port, by moving back again from its position in Diagram II., just as the slide valve of Patent 168,359 has done, and just as does the main valve of every other form of triple valve, except one having the supplemented form of main valve shown in Patent 220,556, the main slide-valve part of which, having once been moved to open the port (as in Diagram II.), is not required to move back again to close it.

Diagram IV. illustrates the position of each valve for a full application. All three main valves—the slide valves of Patents 168,359 and 220,556,* and the stem slide valve (*i, j, k*) of the Boyden structure—have been moved far enough to *fully* uncover the port to the brake cylinder, and to thus permit the auxiliary-reservoir air to flow into the brake cylinder somewhat more rapidly than in graduated applications.

Diagrams I., II., III. and IV., collectively, illustrate *all* of the various functions of the main valve of the "old-fashioned" triple valve; viz., those of opening, partially or fully, and of closing that port which conducts the air from the auxiliary reservoir to the brake cylinder, both in graduated and in full applications of the brakes.

* It is to be understood, of course, that a full application of the brakes may also be obtained by causing the port *through* the slide-valve of Patent 220,556 to register *fully* with the port below it, instead of moving the slide-valve entirely off the port, as shown in the second figure of Diagram IV. But this mode of obtaining a full application does not differ from that illustrated, except that the latter affords a slightly greater access for the same air, through a longer movement of the *same* valve.

Diagram IV.—Showing Main Valve in the Position for a “Full” Application of the Brakes.

Valve of Patent 168,359.

Valve of Patent 220,556.

Valve of Boyden Structure.

Diagram V.—Showing a New Operation of the Boyden Structure, Unknown in the Old Art, by which an Added and Independent Valve (22) Opens an Added and Independent Port to the Brake Cylinder.

Diagram V. shows an additional operation of the Boyden structure, which has no counterpart, nor anything resembling it, in *any* form of the "old-fashioned" triple valve.

The stem valve (*i, j, k*) has here fully opened its port to the brake cylinder, in precisely the same way that it always does for a full application; *but, in addition thereto*, ANOTHER valve (valve 22), *not anywhere found in the "old-fashioned" art*, and which has been idle and inert in each of the previously described customary operations of the main valve, has *here* been moved, by the extreme, or "further," traverse of the piston, and, when so moved, has opened an *additional and independent port* (also *new* to the art) leading to the brake cylinder.

If this structure be used without any partition 9 and restricted aperture therein (as *experimented with in Court*), the opening of this *additional valve 22* will *then* (as presently to be shown) be useless and even injurious (by intensifying shocks—See p. 16 *infra*).

But if the structure be used *with* the partition 9 and its restricted aperture (as is *always* done in practice), *then*, when the *additional valve 22* is thus opened, such a *difference of pressure* ("differential pressures") is thereby produced on opposite sides of the check valve (which controls the admission of train-pipe air) that the check valve instantly opens, and *train-pipe* air pours directly under the check valve and under valve 22 into the brake cylinder, thereby producing both a "quick application" of the brakes on each individual car and a venting of the train pipe at each car, so as to produce quick serial application of the brakes from car to car.

Hence, the Boyden valve exhibited in Court was *not merely* an "old-fashioned triple" valve. On the contrary, it was an old form of triple valve *supplemented* by being provided with a *new valve*, which is opened *only* by the *extreme* traverse of the triple-valve piston, and which is *thus adapted*, upon the

insertion of the partition with its restricted port, to admit *train-pipe* air direct to the brake cylinder.

(c) The fact that the operation of the Boyden valve structure, exhibited in Court, can be changed, by the insertion of the non-moving ring or partition, from that of a valve admitting only auxiliary-reservoir air to that of a "quick-action" triple valve, which admits train-pipe air because of the production of differential pressures on opposite sides of the check valve, does not indicate that Boyden's structure differs substantially from that of Westinghouse. That suggestion is fully met by the fact, pointed out at the last argument and illustrated by a model, that the Westinghouse "quick-action" valve also operates as a "quick-action" valve *exclusively* by the production of differential pressures on opposite sides of the check valve (49), caused by the opening of the emergency valve (41); and that the whole character of the Westinghouse valve can also be changed from a "quick-action" valve to a valve which is substantially only an "old-fashioned triple" (because it admits only auxiliary-reservoir air) simply by the removal of a portion of the *partition* X, and thus enlarging, or doing away with, the *restricted* port, which, when present, holds back or chokes the flow of auxiliary-reservoir air, and causes a lower pressure to exist on the under side of the check-valve (49) than exists on the upper side (*i. e.*, a condition of "differential pressures.")

This is illustrated by the diagrams on the opposite page.

With the removal of portion X, of the partition between the passages for the flow of air from the auxiliary reservoir and from the train pipe, as shown in Fig. 1, the only possible *operation* of the structure is that of an *ordinary* "old-fashioned" triple, because the flow of auxiliary-reservoir air into the passage below the check valve will then be so rapid that the pressure on the lower side of the check valve will prevent its opening, notwithstanding the fact that the valve 41 has been fully

Diagram Illustrating the Necessity of a Partition with a Restricted Port, in the Triple Valve of Patent No. 360,070, to cause "Quick-Action".

Fig. 1.—Partition X Removed. Structure can operate only as an "Old-Fashioned" Triple Valve.

Fig. 2.—Partition X Inserted. Structure becomes a "Quick-Action" Triple Valve.

Diagram illustrating the Necessity of a
 Partition with a Restricted Port in the
 Triple Valve of Patent No. 360,070, to
 cause "Quick-Action"

 operate only as an "Old-Fashioned"
 Triple Valve.

Fig. 2-Partition X Inserted. Structure becomes
 a "Quick-Action" Triple Valve.

opened. The valve 41 and its port then become mere idle and useless parts.

But, with the portion X inserted (so as to provide only a *restricted* port for the flow of auxiliary reservoir air), as shown in Fig. 2, the structure becomes a "quick-action" structure, operating to produce "quick action" upon the extreme movement of the triple-valve piston, and the consequent opening of the emergency port, because pressure from the auxiliary reservoir is thereby choked or held back from the passage below the check valve, and the opening of the check valve (49) is then inevitable, because of the *differential pressures* on its opposite sides.

The experiment before the Court, therefore, when properly understood, does not prove that the Boyden valve differs in any substantial respect from the Westinghouse structure, nor that it operates in any substantially different mode. Nor does the fact that it operates by "differential pressures," and that its mode of operation can be changed from *auxiliary-reservoir air* admission (the "old-fashioned" method) to *train-pipe* air admission for quick action (the new method) by the insertion of the partition or ring 9, differentiate it from the Westinghouse structure, for that valve also operates through precisely the same causes, and it may also be changed from a "quick" action to an "old-fashioned triple" action by a similar simple removal of a restricted port in the partition between the air passages.

(d) These facts also refute another contention of the defense, that a partition containing a restricted port was *first invented* by Mr. Boyden. Such a partition, illustrated by the portion X, constitutes as vital a feature of the Westinghouse valve as it does of the Boyden valve. (See former Brief, p. 58.)

SECOND. A second proposition advanced by defendants' counsel, based upon the Court exhibition, was that a triple-

valve structure operates just as *quickly* and as *powerfully* when acting in the old-fashioned way, simply by admitting auxiliary-reservoir air, as does a Westinghouse "quick-action" valve, operating by the admission of train-pipe air.

The quicker *serial* application of the brakes, which results from the admission of train-pipe air, was *conceded*; but it was claimed that the Court could see for itself that the brakes were applied as quickly, on a single car, by the full application of auxiliary-reservoir air, as they were by the full application of auxiliary-reservoir air *plus* train-pipe air.

All such conclusions from the Court experiments would be very misleading.

The fact is that the application of the brakes by train-pipe air admission to the brake cylinder, in what is known as "quick action," by either the Westinghouse or Boyden valve, is not only *serially* more speedy, but is also *individually* both more speedy and more *powerful*.

This is, in substance, stated in the patent in suit (Patent, p. 787, fol. 1282). The patent states that the air discharged from the train pipe

"is utilized in the performance of preliminary work, it being found in practice that the air so taken from the pipe will exert a pressure of about twenty-five pounds in the brake cylinders."

From this statement, *greater quickness in reaching maximum pressure* and a *nearer approach to maximum pressure* are both necessarily deducible (as we shall next show), and this increased efficiency is proved, without contradiction, as an affirmative fact (*Westinghouse, Rec.*, p. 124, fol. 186).

While it is true that, under no circumstances, can the pressure in the brake cylinders (even in "quick action") be greater than the initial pressure in the main reservoir or in the auxiliary reservoirs (say 70 pounds to the square inch), yet this

statement does not touch the point now under consideration.* The problem was, and is, how *quickly* a *maximum* pressure can be reached by the filling of the brake cylinders with air under the *highest obtainable pressure*, and how near an approximation to the *maximum* pressure can be reached, notwithstanding the inevitable loss of *some* pressure in the act of *expanding into the brake cylinders*.

The Westinghouse quick-action valve of the patent in suit fills the brake cylinders with air under pressure (1) with *greater rapidity*, and (2) with a *nearer approximation* to the *maximum* pressure (70 pounds) than can be done from an auxiliary reservoir only, because,

FIRST. By its use, air under pressure is rushing in *both* from the train pipe and from the auxiliary reservoir, and the cylinders will, of course, fill faster with air under pressure when admitted *from two sources* than from one, other things being equal; and hence the brakes will apply quicker.

SECOND. The air in expanding into the brake cylinder necessarily loses a considerable proportion of its original pressure, because the same air has then to fill a much larger space, and necessarily loses pressure in expanding. It loses pressure in proportion to the expansion.

If, however, *train-pipe* air is rushing into the brake cylinder simultaneously with, or in advance of, the auxiliary reservoir air, and if it contributes *also* to fill the cylinder (exerting,

*The opinion of the Circuit Court of Appeals, at page 875, quotes a remark made in oral argument by one of complainant's counsel to the effect that "quick action" does not involve *greater* power. This remark is true in the sense that no greater power can be exerted *than that in the main reservoir or in the auxiliary reservoir*; but is inaccurate (for the reasons above given), if understood to mean that there is no greater pressure *at the brakes*, when *both* "train pipe" air *and* "auxiliary reservoir" air are utilized, than is the case when "auxiliary reservoir air" *only* is admitted. The contrary is proved and is the fact.

say, 25 pounds of pressure—Patent, p. 787), it is clear that it, to that extent, lessens the degree of expansion, and consequent loss of pressure by expansion, of the auxiliary reservoir air, which would otherwise occur. The *ultimate pressure* in the brake cylinder, and, consequently, upon the brake shoes, will be considerably greater if train-pipe air has been first injected, than if auxiliary reservoir air *alone* was employed.

This reduction of pressure, in expanding from the auxiliary reservoir, is incidentally adverted to several times in the proofs (Record, p. 317, fol. 488 ; 320, fol. 493), although the explanation above given is not found at length in the record. The fact of the existence of both *greater* and *more quickly-attained* pressure, due to train pipe "quick action," was never, however, disputed.

THIRD. As already noted in our previous brief (p. 15), it is not practical "for constructive reasons," to have the opening from auxiliary reservoir to brake cylinder a large one ; hence the brakes were never applied by the "old-fashioned" triple nearly so quickly, by auxiliary-reservoir pressure, as they can be, *and are*, in "quick action", by adding train-pipe pressure also, as utilized in the valve of the patent in suit.

FOURTH. Even though a large opening should be made from auxiliary reservoir to brake cylinder, in the case of a *single* individual triple valve (which was all that was shown in the Court experiments), yet no such large opening can be *thrown wide open* in actual practice, where a *number* of "old-fashioned" triple valves are arranged serially upon a long train. Each succeeding valve would open to a less extent than the one ahead of it in the train, and, while quick *individual* action might be had upon the *first* car, slow individual action only could be obtained upon the last cars. The making of a *large* aperture, which would open *fully* on the front cars, while only small apertures can be opened on the rear cars, would

intensify the disastrous shocks beyond anything which was ever found to exist where a small aperture from the auxiliary reservoir was used on all the cars. Hence, *small* apertures in the valves on *all* cars was the only practical construction.

This is fully explained by Mr. Westinghouse (Record, pp. 317-320), and is undenied.

The Court experiments, therefore, being with a single valve, only, and a single brake cylinder, necessarily failed to demonstrate that equally quick and equally powerful action could be practically obtained from auxiliary-reservoir air pressure alone as by the method of the patent in suit.

III.

The prior state of the art in emergency application of Brakes.

Mr. Hill's description of "development of the triple valve," pages 8-10 of his brief, seems to involve an effort to make it appear that "quick action", or "emergency" application, was not a new thing in air brakes at the date of the present invention.

Defendant's position herein is briefly replied to in our original brief, page 115. A word or two more may be admissible for greater clearness.

"Quick action", as we now understand the term, was absolutely unknown prior to 1886.

The only emergency action provided for or contemplated in the patents thus referred to by Mr. Hill, or to be found anywhere in the prior art, was that which resulted from the use in emergencies of a *slightly* larger port to the brake cylinder, for air from the *auxiliary reservoir*, than in graduating use.

As already explained, and for "structural reasons," in ordi-

nary service use, air was admitted *slowly* or in *limited quantities*, and could not be admitted otherwise from auxiliary reservoirs. When it was desired to stop the train in the presence of danger, the admission of air was *somewhat more rapid*; but—and this is the important point herein—the air thus admitted, for what is *alleged* to have been “quick action”, could not be admitted *in bulk*, and *was the same air* as was admitted in service use or in graduating; that is, it came, in both cases, from *the same auxiliary reservoir* and not from any other source. This obviously involved only a matter of *degree* and not a difference in *kind*.

This is admitted by Mr. Hill in his brief, in the middle paragraph of page 6. Speaking of the several valves of 220,556 (one of which, he says, in the previous paragraph, is “for an emergency”), he adds that they “perform the same kind of function and differ only in the *degree* or manner of performance.”

From this it will be obvious that, when Mr. Westinghouse provided for augmenting or supplementing auxiliary-reservoir air—the *only air previously used*—by taking air *from the train pipe* and charging it into the brake cylinder, by a *large and direct* port, he made an improvement which was different not merely in *degree* but also in *kind*.

How vitally important this change was, we have already shown.

Hence the “quick action” or “emergency” feature of the invention, now in question, is a radically different thing from the “quick action” or “emergency” previously known in the art, and on which so much stress seems to be laid in defendant’s brief.

Mr. Hill, in his brief, under the head “Triple Valve Defective on Long Trains” (pp. 12, 13), has very happily stated and explained the fact that, though a double-traverse piston had been previously used in the automatic brakes of short trains in passenger service, the second or further traverse was

wholly impracticable when the same apparatus was applied to long trains.

It necessarily follows, as a corollary, from this that when Mr. Westinghouse adapted the double traverse feature to the requirements of long trains, *he did something more than merely retain, without change of function, this old double traverse.* Combining it with the means which he devised for charging *train-pipe* air into the brake cylinder, he gave it a new function and a new operation. Hence, in this case, the merit of the invention does not rest solely on the devising of a system of apparatus for supplementing *auxiliary-reservoir* air by *train-pipe* air, but Mr. Westinghouse's merit as inventor is still further enhanced by his *ability* to utilize, and by his *success in utilizing* the "*farther traverse*" of the triple valve piston to do work which it never did before, and to do that work in a place where, as previously organized, it was incapable of being used.

Mr. Hill's brief deals, *also*, with the subject of quicker action by locally venting the train pipe, on pages 14 and 15. He cites a statement from Westinghouse Patent No. 217,838, dated July 22, 1879, as tending to show that the *mere* local venting of a train pipe at intervals along the train was not new.

Patent No. 217,838 is dealt with on pages 110-112 of our principal brief, and it is there shown :

FIRST. That Judge MORRIS distinctly held that this patent not only did not solve the problem of "quick action," but did not take the first really practical step in the direction of practically solving it.

This ruling was not questioned by the Boyden Company on the appeal, nor was any finding conflicting with it made by the Circuit Court of Appeals. On the contrary, that Court distinctly held (p. 880) that the invention of Westinghouse, although defectively claimed (in its opinion), "is one of the

highest value to the public, and *is a pioneer one in the art of quick-action brakes*," and the invention is "conspicuously one of those pioneer inventions which entitle the proprietor to a liberal protection from the Court in construing the claim."

SECOND. The mechanism of Patent No. 217,838 was absolutely inoperative and worthless for practical use.

See Evidence cited on p. 111 of our Principal Brief.

THIRD. Boyden himself admitted that such devices were not practically operative to be used in service (Former Brief, p. 111).

The primary and pioneer character of the present invention of Westinghouse is not impaired by an *unsuccessful attempt* of the same inventor, many years previously, to accomplish a *portion* of the same results.

In fact, the conclusion to be drawn from Westinghouse's unsuccessful attempt, seven or eight years earlier, is favorable, rather than unfavorable, to the pioneer character of his claims, when considered in connection with the present invention.

That Westinghouse himself had before attempted to solve the problem, and had failed to do it, is a high tribute to the importance of the present invention and to the difficulty of solving the problem which was solved by the invention of the patent in suit.

The greater individual efficiency of the brakes, combined with *greater rapidity in serial application*, and all under the control of the engineer, so that the apparatus was capable of the most delicate, as well as full, action in service work, and also the most energetic and powerful action in emergency work, was a problem which *had not even been attacked* until it was attacked by Westinghouse.

It has been said that nothing so strengthens the presumption in favor of a patent as an unsuccessful attempt to over-

throw it (*Sargent vs. Seagrave*, 2 Curt., 553); and it may also be said that nothing is more pertinent, upon the question of the essential novelty and utility of a patent, than earlier and unsuccessful efforts to accomplish similar results, which efforts have been abandoned or have never gone into practical use, and which even the defendant, who relies upon them, cannot assert are now practical.

IV.

The Scope of the Patent in Suit.

Mr. Hill, in his able brief, on page 23, discusses this question under the heading "*What is 360,070 entitled to cover?*" He states that the patent is not entitled to cover *merely* the prevention of shocks, nor *merely* local venting of the train pipe, nor *merely* the utilization of the extreme traverse of the triple-valve piston for another purpose (viz., the admission of reservoir air).

But none of these things, *in themselves*, are claimed in the patent in suit, nor has there been any effort to claim or cover them.

Mr. Hill then goes on to state what, in his opinion, the patent *is* entitled to cover. He says (p. 23):

"It was entitled, however, to cover a mechanical device; namely, the auxiliary valve 41 governing the special by-passage leading directly from the train pipe to the brake cylinder."

And, again (*Id.*):

"In other words, Patent 360,070, while not solving the problem of quick action, furnished for its subsequent solution by Mr. Westinghouse an important *factor*, consisting of the auxiliary valve and its by-passage, arranged to be put into action by the extreme traverse of the triple-valve piston. This Patent, 360,070, did not itself accomplish the desired result;

but it furnished an *element* for the subsequent combination by which Mr. Westinghouse finally achieved that result. *It should be construed, therefore, as a patent for that element or factor, broadly, and for nothing more.*"

(The italics are Mr. Hill's.)

Mr. Hill, in this and other passages throughout the brief, concedes what is undisputed ; that is, the pioneer character of Westinghouse's invention. Indeed, no contention has ever been made that the Westinghouse claims are not entirely valid, so far as novelty is concerned. The only question raised against any of them (in the line of validity) is the attack upon the second claim, due to its alleged defectiveness of form.

If Mr. Westinghouse was, as he is thus conceded to have been, the first person who ever constructed a brake apparatus in which a triple-valve device was provided with an auxiliary valve governing a passage leading directly from the train pipe to the brake cylinder, and if, as is also conceded, he accomplished thereby a perfectly novel and highly valuable result, why, in the name of common sense, and of the uniform rule of construction of patents of this character, should he be limited, as Mr. Hill claims, to "*the* auxiliary valve 41," or to "a special *by*-passage."

Is not Mr. Westinghouse entitled, also, to cover all combinations which are the equivalent of his, even though the forms of the individual parts may widely vary from his forms ? Is he not so entitled at least as much as any other inventor, and more so than most inventors ?

Did the essential novelty of his invention rest in "*the*" valve 41, or in its particular location in the structure, or in its particular shape ? On the contrary, was not the invention broader than that ; to wit, the combination, with a triple-valve structure, of an emergency valve which should open a direct passage from train pipe to brake cylinder when the valve structure is subjected to a rapid reduction of pressure, as described ?

Why is Mr. Westinghouse to be limited to a *particular passage* for the train-pipe air; or why must he be limited, still more closely, to a special *by*-passage for such air?

Did his invention lie in the special character or location of such passage?

We think not.

In *Western Electric Co., La Rue*, 139 U. S., 601, this Court took occasion to say, in overruling a narrow and limited construction of a patent for a useful invention:

"Since the case of *Winans vs. Denmead* (14 Howard, 330) it has been settled doctrine of this Court, as expressed in the opinion of Mr. Justice CURTIS, page 343, that, the patentee having described his invention, and shown its principle, and claimed it in that form which most perfectly embodies it, is, in contemplation of law, deemed to claim every form in which his invention may be copied, unless he manifests an intention to disclaim some of those forms."

The same case of *Winans vs. Denmead* contains the following statement:

"Where form and substance are inseparable, it is enough to look at the form only. Where they are separable—where the whole substance of the invention may be copied in a different form—it is the duty of courts and juries to look through the form for the substance of the invention: for that which entitled the inventor to his patent, and which the patent was designed to secure. Where that is found, there is an infringement; and it is not a defense that it is embodied in a form not described and in terms claimed by the patentee."

To the same effect is the opinion of this Court in *Machine Co. vs. Murphy*, 97 U. S., p. 120, cited on our previous brief (p. 52).

The pioneership of the patent in suit is expressly admitted by Mr. Hill in his brief, on page 52, as follows:

"Tested by this rule, the patent in suit, 360,070, was pioneer as to the auxiliary valve 41 and its *by*-passage, covering them and their mechanical equivalents, in whatever form they may be used."

As we have clearly shown, in our previous brief, that the de-

fendant's structure contains an "auxiliary valve" (22), and that the function of that valve is to admit *train-pipe air* direct to the brake cylinder, by being pulled off its seat by the extreme traverse of the triple-valve piston, and that the defendants' structure also contains the other prerequisite, viz., the preliminary traverse of the piston, which, through *another valve (i j k)*, admits air from the auxiliary reservoir to the brake cylinder, for service use, it is clear that this statement of Mr. Hill's is sufficient to cover the case of the defendants' structure, unless too much stress be laid upon his phrase "*by-passage*."

The defendants' passage from train pipe to brake cylinder is a *through* passage, instead of a *by-passage*, but, perhaps, on this account, it is all the more a *direct* passage, which is the only essential characteristic of the passage referred to in the Westinghouse claim.

V.

The Position of the Court of Appeals.

In discussing the question of infringement, the Court of Appeals in the present case (at foot of page 881) used the following argument, as negating infringement by the Boyden structure:

"But Boyden simply substituted in the original triple valve his poppet valve 22 for the slide valve which is the main valve of Patent 220,556. Boyden's is not an 'auxiliary' valve; it is mechanically the original main valve of the original triple valve, and it performs the service which is performed by the main valve of 220,556. It is not the mechanical equivalent of valve four in the attached apparatus of Westinghouse simply by reason of its taking part in an emergency service in admitting train-pipe air into the brake cylinder; in the original triple valve it performed no other service than admitting auxiliary reservoir air into the brake cylinder; in Boyden's device it

continues to perform that service, and is made incidentally instrumental in allowing the passage of train-pipe air. The performance incidentally of quick-action service does not make it an auxiliary valve. It is the same valve. The incidental service is auxiliary, but the valve itself is the same and unchanged."

Here is a singular misapprehension of fact, and, as we submit, of law also.

FIRST. *As to the fact.*

As already shown, valve 22, when the Boyden structure is complete, and the partition 9 in its place, does not admit auxiliary reservoir air to any practical extent, nor does it perform any function of a "main valve" (as that term has always been used in the art) to any appreciable extent, and especially on long trains.

This was, in substance, held by Judge MORRIS (Rec., p. 844, fol. 1365), it was admitted by Boyden (Rec., pp. 578-9, x-Qs. 214-216), and is a physical necessity from the construction of the apparatus.

Valve *i, j, k*, does all the "main-valve" work until main-valve work is no longer necessary to be done, because the brake-cylinder is practically full.

After that, it is possible that, by very careful manipulation, valve 22 may be opened to admit from three to five per cent. more air. But by that time the brakes are "on" with practically maximum force, and the train is so nearly stopped that so small a percentage of increase at that time cuts no appreciable figure in train control. That such increase, small as it is, ever takes place in *practice* is denied, and that it ever can take place at all, *except on short trains*, is not even asserted.

On the other hand, the recognized, admitted, prominent and *useful* function of valve 22 is to admit *train-pipe* air directly to the brake-cylinder, when pulled off its seat by the extreme traverse of the triple-valve piston, and it does that work as auxiliary to the valve, *i, j, k*, which is utilized for

"almost, if not all" admissions of auxiliary reservoir air, in service work.

How the Court of Appeals could then term this "quick-action" operation a mere "incidental" performance, it is difficult to understand.

It is the primary and only really useful service or performance for which the valve exists.

These points are elaborated on pages 38-48 of our former brief.

SECOND. As to the law :

Has it ever been heard that a party may infringe a patent by doing it "incidentally?"

If the combination of apparatus in the defendants' structure is substantially the same, as to its parts and its essential mode of operation, is it any answer to call the service which it performs, and by which it is identified as to its similarity to the patented apparatus, an "incidental" service."

We think not, and we think that no decision of this or any other Court will be found which will make this a governing consideration.

VI.

The contention as to the alleged invalidity of the second claim of Patent No. 360,070.

This has been discussed on pages 79 to 82 of our former brief, and we think it does not need much further consideration.

The able and ingenious brief of Mr. Church, filed on the former argument, is not sound in its comparison of the second

claim of the patent in suit with the eighth claim of the Morse Patent.

The Morse eighth claim (15 How., 112) was, baldly, obviously and expressly, a claim for the communication of intelligible signals at any distance by the use of the electric current, "however developed," absolutely irrespective of the use of any particular mechanism.

The second claim of Patent No. 360,070 bears no fair comparison with Morse's eighth claim. It reads as follows (with two obvious insertions):

"In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, and a triple valve having a piston whose preliminary traverse [*by opening a port*] admits air from the auxiliary reservoir to the brake cylinder, and which by a further traverse [*by opening a port*], admits air directly from the main air-pipe to the brake cylinder, substantially as set forth."

We have inserted in the phraseology of the claim the two parenthetical statements "*[by opening a port,]*" because they are necessarily and obviously implied in the language actually used.

Air under pressure cannot possibly be admitted from one chamber, or reservoir, to another, *except by opening a port*.

To insert the words, or to leave them out, therefore, neither adds to nor subtracts from the claim. If the claim is not open to objection with these words *inserted*, then it is not open to objection with the words *omitted*, because they are necessarily implied.

Of course, the claim is not limited to any particular special or *connecting* mechanism, by and through which the triple-valve piston acts to open, or "controls," the port which admits the air.

This is, in effect, conceded by the defendants themselves, when they concede (as they do in their brief) that the valve of the New York Air Brake Co. (see p. 34 of Mr. Hill's brief)

embodies the substance of this second claim, although the connection between, and control over, the emergency valve by the triple-valve piston is absolutely and entirely different from that illustrated in the patent in suit, and involves a separate and subordinate, although important, invention.

In admitting therefore—as the truth, of course, compels them to admit—that the valve of the New York Air Brake Company (illustrated opposite p. 34 of their brief) was correctly held to be an infringement of the second claim of the patent in suit, they impliedly admit that that claim was not, and is not, limited to any special mechanism by and through which the triple-valve piston controls or opens the emergency port.

Hence, on the defendant's own admission, the second claim is not fatally defective, through omitting to specify the special connecting means; and, as every other element is expressly or implicitly stated in the claim, there can be no sound contention that the second claim is invalid for lack of specifying the means.

Mr. Hill also attempts to make the same point, in the following extract (p. 29) from his brief:

“The expression ‘whose preliminary traverse admits air from the auxiliary reservoir to the brake cylinder, and which by a further traverse admits air from the main air pipe to the brake cylinder,’ is simply the expression of a *result*.”

And therefore, as he alleges, is obnoxious to the doctrine of *Morse vs. O'Reilly*.

This is hardly correct. The *result* is the stopping of the train. The passage thus quoted is a specification of the *operation* by which the *result* is secured.

VII.

The criticism upon Judge Morris' decision sustaining the charge of infringement.

We think the Court of Appeals erred in its interpretation of the language used by Judge MORRIS, in holding that the Boyden structure infringed the second claim of the Patent No. 360,070.

While the reasons for the conclusions of the learned Judge might, perhaps, have been more happily expressed, we think that the meaning thereof is clear, and that, when correctly understood, his position is not justly subject to the criticism made upon it.

The foundation of what Judge MORRIS said was this (p. 848) :

" If the Westinghouse Patent now in suit is for an invention of a primary character, and *if the gist of that invention is the use of the further traverse of the triple valve piston to open a valve which admits air directly from the train-pipe to the brake cylinder, with the result that the train-pipe is vented and the train-pipe air utilized*, then it appears to me that the defendant cannot exculpate itself from the charge of infringement by the fact that in its device the train-pipe air is admitted through the triple valve chamber and not through a by-passage, nor by the fact that, in its device, the further traverse of the piston opens the main valve in a special manner, which produces the same result, but does not make use of a separate auxiliary valve, provided Westinghouse has not, by the explicit terms of his claim 2, restricted himself to the use of an auxiliary valve.

" I do not think that Westinghouse has so restricted himself in claim 2, although he does appear to have done so in claims 1 and 4." (Italics ours.)

We submit that Judge MORRIS was misled by the ingenuity of the defendants into making the statement that the valve 22 of the defendants' structure was not a separate auxiliary valve.

We say that he was misled, because at another part of his

opinion (p. 844, fol. 1365) he admitted that it was the valve *i j k* that

"probably in most cases does do the work of ordinary braking," and

"the main valve 22 becomes non-essential, or, *if* lifted off its seat, is *moved very gently*."

This shows that valve 22 is not in reality the "*main valve*;" that it is in truth and in fact a separate auxiliary valve and does auxiliary work, and that it was primarily and substantially exclusively intended to do "*quick-action*" work by admitting train-pipe air, and that only occasionally, by very careful manipulation, could it be made to do auxiliary-reservoir work in connection with the true "*main*" valve *i j k*.

Such being the case, we submit that Judge MORRIS, to be correct, should have held that the first and fourth claims, also, were infringed.

But, as Judge MORRIS well remarked, the *second* claim does not contain such specific language as the first claim as to the exact character of the valve which is to admit train-pipe air.

In that *second* claim it is not strictly required that such valve should be "*independent of the main valve*."

Hence, if it is such a valve, at all, as to do the work required by the claim, upon the extreme movement of the piston, and if there be another valve which admits auxiliary reservoir air upon the preliminary movement of the piston, the substance of the invention is found and the language of the second claim is satisfied.

But after clearly and correctly, as we submit, defining the gist of the invention, Judge MORRIS went on, at a subsequent part of his opinion, to use the language criticised.

In this paragraph Judge MORRIS (Opinion, p. 846) states that, in examining

"mechanisms actuated by air under pressure", in which "the transmission of power is not visible to the senses as plainly as when it is done by cranks and levers," * * *

“ the functions of the instrumentalities by which it operates are more important than their forms, and in judging of an infringement we are to direct our minds rather to functional equivalents than mechanical equivalents.”

In this there was no *real* error, although the language has been read as implying a conflict with recognized principles.

What the Judge plainly intended to say was that, where the instrumentalities through which mechanisms act, as in the case of air pressures, are invisible, the *functions* which the parts perform are a truer *indication of the essential character* of those mechanisms than are the mere visible mechanical forms, because the *mere mechanisms* are not the actual operative agencies for producing results, while the invisible air pressures are the true agencies. Hence, in comparing mechanisms operating by invisible air pressures, and in comparing the action of air pressures with one another, as made operative in different mechanisms, and in therefrom determining the real character of the mechanical parts, it is entirely correct to say that what those parts *do* (*i. e.*, their *function*) is really more important than their forms, in determining *equivalency*.

Properly understood, therefore, Judge MORRIS' statements of the points to which attention should be directed, in any inquiry of this kind, is not open to fair criticism.

The Sum Total of Defendants' Case.

Defendants' entire case is summed up in one italicised line of Mr. Hill's brief (p. 35), thus :

“ *In this [Boyden] device, no auxiliary valve or by-passage is employed.*”

If this one statement is erroneous, then defendants have no case.

1. The Boyden valve 22 is either *the* main valve or it is *not*. So much is clear.

2. If the Court will turn back to page 5 of Mr. Hill's brief, and to the skeleton drawing facing that page, it will be seen that the main valve, colored black, is there represented to be the valve which admits air from *the auxiliary reservoir* to the brake cylinder.

3. The proofs show—and it is not denied—that, in the graduating and service use of the Boyden apparatus, this work of admitting air from *the auxiliary reservoir* to the brake cylinder is done by the stem valve *i, j, k*, and that valve 22 does not, in such use, open at all until *substantially all* the work of braking is thus performed.

4. This being so, *i, j, k* is the Boyden "main valve," and the Boyden valve 22 is *something else*.

5. Being *something else*, and, in its action for emergency purposes, being *auxiliary* to the main valve *i, j, k*, it becomes an *auxiliary valve*. It *can* be nothing else.

As to what "auxiliary" means, see the first three lines of page 4 of Mr. Hill's brief. Apply this definition of Mr. Hill's to the Boyden valve 22, and it is clear that it is an *auxiliary* valve.

6. We believe that we have already made it clear that the Boyden air conduit F through his piston 16, and through the valve 22, is a *by*-passage—as much so as the Westinghouse. It goes "*by*" or past the auxiliary reservoir without charging train-pipe air into such reservoir, but conveys it *direct* to the brake cylinder.

Hence, it is submitted that defendants' case, as thus summed up in a single line by defendants' leading counsel, is based wholly on errors of fact and a misuse of names.

What Complainant's Said in the Court of Appeals.

Mr. Hill, in his brief (p. 30), makes some citations from our briefs in the Court of Appeals, as involving a *supposed* more limited view of the invention than that now presented in this Court. Such was no part of our view of the case then or now. Everything we then said of the Westinghouse invention we also said and now say of the Boyden valve. It has a "quick-action attachment, consisting of an air conduit or passageway, directly from the train-pipe connection to the brake cylinder."

Such "an air conduit or passageway" will be found in the Boyden triple valve, through the piston at F, through the side ports uncovered by the valve 26, and through the port uncovered by the valve 22, as illustrated by blue lines in Fig. 22, facing page 40 of our original brief.

And that air conduit or passageway goes "directly from the train-pipe connection to the brake cylinder."

And it has "a valve [22] to control it."

And in the broad, general sense of the term, it is an "*attachment*," as much so in one case as in the other.

In Westinghouse this "air conduit or passageway" is bored through the triple-valve *casing*; in Boyden it is bored through the triple-valve *piston and casing*.

We also said, and say yet, that this new quick-action feature or element was, in substance and effect, "another brake mechanism." So it is in the Boyden valve. For ordinary service use, the Boyden triple piston opens the stem-valve ports *i, j, k*, by the preliminary traverse of the piston, and thereby substantially all the work of ordinary braking is done. The additional brake mechanism, represented by the further traverse of the piston, by the passageway through it, and by the valve 22, are then inoperative and inert.

But when "quick action" is required, then *they*, as an *additional* brake apparatus, and auxiliary to the *service* apparatus, are brought into operation.

Hence, what we then said, being as true of Boyden as it is of Westinghouse, cannot be used as an admission that the Westinghouse claims here in controversy are to be limited otherwise than in accordance with their terms.

And this same comment applies to what Mr. Hill says under "Fourth," page 50.

And, as the same quotations are made by Mr. Fenton in his brief (p. 9), we make the same reply to him.

Two Inaccuracies.

BOYDEN 1883 PATENT: Of this, Mr. Hill says (p. 16) that, by it,

"compressed air could be transmitted directly from the train pipe to said valve chamber and thence to the brake cylinder, *to augment the pressure of the brakes.*" (Italics are ours.)

The exact facts in this regard are presented in our original brief (pp. 106, 107) by extracts from the testimony of Mr. Boyden himself. By comparing what Mr. Boyden says with what Mr. Hill says, the misleading character of the latter will be obvious.

PATENT OFFICE ACTION: The idea, not merely suggested, but positively asserted by Mr. Hill (p. 55), that the *ex parte* statements made by Mr. Boyden in the descriptive part of his specification, are "officially endorsed as true" by the Commissioner of Patents, "by granting the patent which contains them," etc., hardly does justice to Mr. Hill's knowledge either of law or of Patent Office practice.

And, as this includes one of our assignments of error in our application for a *certiorari*, we summed up the facts and the law with some fullness in our original brief (pp. 83-91);

and, in so far as what Mr. Hill says differs therefrom, we submit with confidence that he is in error.

We submit that the decree of the Circuit Court of Appeals should be reversed, and the cause remitted to the Circuit Court with directions to enter a decree for complainants on the *first*, *second* and *fourth* claims.

Respectfully submitted,

GEORGE H. CHRISTY,

FREDERICK H. BETTS,

Counsel for Complainant.

Supreme Court of the United States.

GEORGE WESTINGHOUSE, JR., ET AL.,
Appellants,

vs.

BOYDEN POWER BRAKE COMPANY ET AL.,
Respondents.

No. 116, October
Term, 1896.

Brief on Behalf of Appellants in Connection With the Memorandum of this Court of January 24th, 1898.

The Court has directed the attention of counsel upon this argument—

“ particularly to the inquiry whether, in view of the state of the art, including the patents to Westinghouse, the proceedings in the Patent Office, and its own terms, the patent sued on can be sustained as a patent for a process or method.”

In this brief, we discuss these questions chiefly, referring to our former briefs for more detailed consideration of all the various issues which have arisen.

We understand the memorandum to, in substance, suggest the inquiry whether the patent in suit (Westinghouse Patent No. 360,070) is one to which the rule formulated by this Court in *Morley Sewing Machine Co. vs. Lancaster*, 129 U. S., p. 263, is applicable.

This Court then said (p. 284) :

“ But in a pioneer patent, such as that of Morley, with the four claims in question, such as they are, *the special devices set forth by Morley are not necessary constituents of the claim.* * * * ”

And again (p. 277) :

“ The doctrine thus applicable to a machine patent is of a kindred character with that applied, in this country and in England, to a *patent for a process.* ”

This rule has been applied even to the extent of ignoring the literalism of claims, when the justice of the case so requires.

Hoyt vs. Horne, 145 U. S., 302.

We proceed to show :

- 1st. That Westinghouse's Patent in suit is a pioneer one ;
- 2d. That nothing in the prior art impairs the scope of its claims ;
- 3d. That the proceedings in the Patent Office do not limit it so as to permit the escape of the defendant.
- 4th. That the claims are so worded as to make the form of the special devices for carrying out the method of operation unessential ; and hence that the liberal rules governing a patent for a process are applicable.

First Point. *The Westinghouse Patent is a pioneer one.*

(a) The "result" achieved by Westinghouse in the patent in suit was new.

What was the "new result?"

The "NEW RESULT" was a NEW BRAKE HAVING A NEW MODE OF OPERATION AND NEW USES AND CAPACITIES.

The patent says (Rec., p. 782) :

"The object of my invention is to enable the application of brake shoes to car wheels by fluid pressure to be effected with *greater rapidity and effectiveness* than heretofore, more particularly in trains of considerable length, as well as to *economize compressed air* in the operation of braking *by utilizing in the brake cylinders the greater portion of the volume of air which in former practice was directly discharged into the atmosphere.*"

Mr. Westinghouse says (Record, p. 116) :

"The construction of 'quick-action' automatic brakes is such as to provide for *all of the requirements of service stopping* equally as well as those functions have heretofore been performed by the 'automatic' brake system, and they are *additionally arranged* so that when 'emergency' stops are made there is *practically no delay* in the *full* application of the brakes, and there is also a *considerable augmentation of power* as compared with that available in service applications."

"The features of *substantially instantaneous action and augmented power* in *emergency* applications constitute the distinguishing features of the quick-action automatic brake as compared with the ordinary automatic brake."

Mr. Barnes says of the feature of augmented force (Record, p. 405) :

"The great increase in safety that resulted from the use of quick action triple valves is apparent, as it was found impossible to use a plain triple valve with a forcible action on long trains."

Mr. Boyden (defendant's expert) says (p. 657):

"In making an application of the brakes (nota 'quick action'), the reservoir pressure would exert about 50 pounds on the piston in the brake cylinder, but when making a *quick* application of the brakes, there would be about ten pounds more exerted on the piston over that exerted from the auxiliary reservoir pressure alone, making in all about 60 pounds pressure."

Mr. Westinghouse says (p. 124):

"The effect of this modification" (discharging train-pipe air into the brake-cylinder) "was to cause a considerable amount of the pressure in the train pipe to pass into the brake cylinder, where it contributed to that regularly supplied by the auxiliary reservoir, augmenting the brake force fully twenty per cent. in emergency or quick-action applications."*

See, also, Newbury (p. 258, x-Q. 346):

"A. As before stated, the brake-cylinder pressure, when making a quick-action or emergency application, with the Westinghouse quick-action triple valve, is about 60 pounds, when main air or train-pipe pressure before the sudden reduction is 70 pounds, while, with the same apparatus, in making a service-stop application, the brake-cylinder pressure is about 50 pounds, with a train-pipe pressure at 70 pounds, as before stated."

The essential characteristics of the "new result" were, therefore, a new brake having combined (1) more rapid and more powerful individual action in emergencies; (2) more rapid serial action; (3) unaltered capacity for "service" work; and (4) a capacity for use,

* It will be observed that Mr. Westinghouse and Mr. Boyden both agree as to the amount of augmented force availed of in "quick action."

Mr. Boyden placed it at an addition of ten pounds to a normal pressure of fifty pounds, which is the same as twenty per cent.

The opinion of the Court of Appeals, at page 875, quotes a remark apparently made in oral argument by one of complainant's counsel to the effect that "quick action" does not involve greater power than "service" action. This remark is only true in the sense that no greater power can be exerted than that which is stored in the main reservoir (70 lb.), but is admittedly inaccurate (as shown by the evidence above) if understood to mean that there is no greater pressure in the brake-cylinders when both train-pipe and auxiliary-reservoir air are utilized. The contrary is the fact, as was fully illustrated by a practical experiment in this Court at the last hearing. The Court of Appeals were, perhaps, misled by an inaccurate remark of counsel.

or exclusion from use, as the engineer may determine under the varying requirements of train-control.

We do not mean that no *part* of this result had been attempted before, nor that suggestions looking *partially* in the required direction had not been made.

As in the case of all other long-desired results, there had been previous attempts.

Westinghouse himself, eight years before, had *tried* to accomplish a *small portion* of the result (by his Patent No. 217,838 of 1879).

We shall deal with this aspect of the case later on.

What we now assert (and it is absolutely uncontradicted) is that as a *practical matter* a "quick-action" brake suitable for use on heavy and long trains (both for emergencies and ordinary use) had never prior to Westinghouse's invention of the patent in suit (in 1887) been in fact produced by any one.

More than that, no one had even contemplated what the *whole* problem was, and even Westinghouse had only attempted to solve a *part* of that problem (by his Patent No. 217,838), and had *failed* in the attempt.

The Court of Appeals decided this when they said (p. 872) of the prior Patents Nos. 217,838 and 220,556 :

"The mechanism of the patents just named did not provide effectively for sudden emergencies, and therefore failed to meet a *great necessity of the service.*"

And Judge MORRIS said (p. 847) :

"It is true that in searching for some device which would give quick action, Westinghouse had, before the date of the patent in suit, conceived the idea that it might be accomplished by venting the train pipe at intervals along the train. He had tried having two or three vents at intervals in the length of the train controlled by electrical apparatus, and also had tried relief valves placed in pipe coupling of each car which would open to the atmosphere and vent the train pipe quickly in case of accident or other sudden release of pressure in the forward part of the train. This was shown in the Westinghouse Patent No. 217,838, July 22, 1879, *but neither of these attempts were successfully applied, and they did not solve the problem of quick action.*"

(b) Westinghouse's invention of the "quick-action" brake was a pioneer or fundamental one, because, as an actual fact, it "lay at the bottom of" (to use the words of this Court in *Cochrane vs. Deener*, 94 U. S., p. 780) the application of power brakes to long freight trains; and, as freight trains are practically always long, it may be said to have lain at the base of modern freight train brake equipment.

Mr. Westinghouse's "quick-action" brake was immediately adopted (p. 132, fol. 198), and, at the time the evidence was given, 125,000 brakes embodying this invention (principally in the improved form of Westinghouse Patent No. 376,837) had been supplied by the complainant company (p. 135, fol. 202), and it is safe to say that, at the present time, more than five hundred thousand freight cars, in the United States alone, are equipped with brakes which use (in the combination of the 1st claim) "an auxiliary valve" controlled by the triple-valve piston, for admitting train-pipe air for "quick-action" (1st claim), or which use (in the combination of the 2d claim)

"a triple valve having a piston which, by a preliminary traverse, admits air from the auxiliary reservoir to the brake-cylinder, and which, by a further traverse, admits air from the train-pipe directly to the brake-cylinder."

At the trials of the Westinghouse brake in suit, the distance in which a 50-car freight train, running at 20 miles per hour could be stopped was reduced to 200 feet, from a previously required distance of 350 feet with the best-known type of brake (Westinghouse, p. 134, fol. 201).

The invention has produced, also, a complete change in passenger car equipment.

Mr. Westinghouse says (Record, p. 132):

"The increased efficiency in train stopping, resulting from the improvements from the invention of the quick-action air-brake, has also been realized in *passenger car brakes*, and a passenger-train can be stopped in a distance from 25 per cent. to 40 per cent. less with the quick-action brakes than when the prior 'automatic' system was used. This important improvement has been taken

advantage of by the principal railroads of the country, and *most of the equipment has been changed from the old to the new type.*" *

See, also, Mr. Barnes' very full statement of the new and great results achieved (Record, p. 404, fols. 628-9).

He concludes as follows (p. 405) :

"With the plain brake, on twelve passenger cars equipped as prior to 1887, at a speed of 40 miles an hour, it required 862 feet to make a stop, while with 20 freight cars, equipped with quick-action triple valves, a stop was made in 459 feet. These results are the average of many experiments.

"With a fifty-car train, such as shown on the drawing, running at 20 miles an hour, it required 1,800 feet to make a stop with hand brakes, while, with the same cars, using the quick-action triple valves, a stop was made in 100 feet. The great increase in safety that resulted from the use of quick-action triple valves is apparent, as it was found impossible to use a plain triple valve with a forcible action on long trains."

Surely, then, within the rule of decided cases, Westinghouse was a pioneer in this new departure.

Such vital and important changes in a great industry arising from the introduction of an invention are characteristic of a "pioneer patent."

If the specific result is essentially new, it is not necessary, to constitute pioneership, that the industry as a whole should be created by the invention.

In *Morley vs. Lancaster* (129 U. S., p. 264), the new point of the invention was the automatic machine for sewing buttons of a particular kind (with heavy heads) on fabric (see p. 273).

In *Consolidated Safety Valve Co. vs. Valve Co.* (113 U. S., 157), the Richardson valve was not the first safety valve, but it was a "pioneer" because it relieved pressure without unduly reducing it.

* The universal equipment of *passenger* cars with the Westinghouse invention proves the great practical value of the *augmented force* and quickened *individual* action of the mechanism of the patent in suit, quite apart from quick *serial* action. No passenger trains are long enough to require the quickened serial action, yet the invention of the patent in suit has been universally applied to them. The very first form of "quick action" apparatus (that of the patent in suit) in which serial action, although quickened, was not sufficiently quickened to avoid disastrous shocks on very long trains was, therefore, adequate of itself to produce a "revolution" in *passenger* service.

In *Clough vs. Barker* (105 U. S., 106), the gas burner of Clough was not the first regulatable gas burner, but it was a pioneer because "Clough was the first person who applied a valve regulation of any kind to the combination to which he applied it."

In *Tilghman vs. Proctor* (102 U. S., 707), Tilghman was not the first person to produce fat acids and glycerine from fatty bodies, but he was a pioneer because he was the first to do it by the action of water at high temperature and pressure.

In *Proctor vs. Beemis*, 36 Ch. Div., 740 (cited in *Lancaster vs. Morley*) the patentee was not the first to automatically supply fuel at intervals to a fire, but he was a pioneer because he was the first to do so "by an intermittent radial action" similiar to the action of a human arm.

In *Winona vs. Deering*, 155 U. S., 286, Steward was not the first to add an adjuster for the butts of grain, but he was a pioneer because he was the "first to invent a *piroated extension* to a butt adjuster."

(c) Westinghouse's invention here in suit is not only a pioneer invention, or one which caused a "new departure" or "revolution" in air brake practice, but it is one which in some respects was admittedly out of the line of previous thought upon the subject. Westinghouse—like all others skilled in the air-brake art—was called upon, in 1887, to devise a brake which would meet the modern conditions of freight train practice, viz., the control by fluid pressure of very heavy and long trains pulled by very heavy locomotives.

No known brake was at that time adequate to meet these conditions (Barnes, pp. 404 and 628).

A brake which was both quicker in serial action from car to car, and also more powerful and quicker in action on individual cars, was required.

Westinghouse solved this new problem by a most surprising expedient. He accomplished *both ends by the same means*. He made a more powerful and quicker acting brake by suddenly discharging ("venting") into each brake cylinder, for emergency stops, the air at *reduced pressure* contained in the train pipe.

Judge MORRIS, in the Circuit Court, well characterized this as a "paradoxical and startling" method of solving the problem. He said (Record, p. 845):

"Now, although quick-action emergency brakes were being sought for, no one before Westinghouse had accomplished this result, and the means by which he accomplished it were entirely novel. Indeed, upon first impression, it is paradoxical and startling to find that, when a *sudden, quick and powerful* application of brakes is needed in the face of impending danger, it is to be obtained by a *sudden large release of the pressure* in the train pipe, to the extent of 15 or 20 pounds below that in the auxiliary reservoir, and that *by using this low pressure air* to operate the brake cylinder, instead of the air under greater pressure stored in the auxiliary reservoir, this remarkably effective application of the brakes is obtained."

And not only was this "*means*" of obtaining quick and powerful action—*i. e.*, by utilizing "train-pipe air" to fill the brake-cylinder—absolutely novel, but even the mechanical instrumentality by which this was done, to wit, utilizing the "further traverse" of the triple valve piston for that purpose, was also a startling and novel expedient, because it was utilizing the very feature which (as admitted by Mr. Hill in his first and principal brief, p. 12) *was the very cause of the impracticability* of quick action on long trains, with the best form of automatic brake previously known.

Mr. Hill then said (p. 12) in his history of the development of air-brakes:

"The triple-valve thus slowly evolved from the original form of Patent No. 141,685, August 12, 1873, to the highly improved form of Patent No. 220,556, October 14, 1879, and in the latter form used by the complainant without further material improvement until the year 1888, was satisfactory for short trains consisting of eight or ten cars or less, but on long trains consisting of forty or fifty cars or more, *it was not only unsatisfactory but absolutely impracticable; and its impracticability resulted from the very fact that the piston had the two traverses* referred to by Mr. H. H. Westinghouse, at the bottom of p. 123, namely, a partial traverse for graduating purposes, and a full traverse for emergency stops."

What can more surely indicate and characterize a fundamental invention than the two features thus admitted to be surprisingly novel, *viz.*, the use of "*low pressure*" train-pipe air to produce *quicker and more powerful* brake action than the higher pressure auxiliary

reservoir air, and the use of the *double* traverse of the piston as the governing feature of the mechanism for producing quick serial action, which had been the very cause why quick serial action, in the best form of prior brakes, had been "absolutely impracticable."

(c) But the pioneer or fundamental character of the Westinghouse invention was *not* only demonstrated by the fundamental change in freight and passenger brake equipment, and by the wide adoption of the invention, and by the surprising conversion of the very means which were the cause of prior failures into an element of success for accomplishing the purpose, but all the adjudications upon this patent have been to the same effect.

Thus Judge MORRIS said in the Circuit Court, in the present case (Record, p. 845) :

"In the domain of quick-action brakes, this device would seem to belong to that class of pioneer inventions the patents for which are to be construed so as to be co-extensive with the real invention, if the language of the claim will permit it."

And, again (p. 847) :

"The problem was not solved ; indeed, the first step in the direction of solving it does not appear to have been taken until the experiments which led to the Westinghouse patent now in suit."

And the Court of Appeals in the present case said (Record, p. 880) :

"That this invention of Westinghouse, thus undefined, is one of the highest value to the public, and that it is a pioneer one in the art of quick-action air brakes is not denied and is conceded. It is conspicuously one of those pioneer inventions which entitle the proprietor to a liberal protection from the courts in construing the claim."

And in the Second Circuit in the suit of *Westinghouse Co. vs. New York Co.* (63 F. R., 962), Judge LACOMBE, referring both to the patent in suit (No. 360,070) and its successor (No. 376,837), said :

"Both of these inventions achieved great necessities and overcame great hindrances ; each is an indispensable part of the bridge which carried railroad car builders from failure to success ; both were products of the inventive genius of the same man ; nothing anticipating either is shown.

* * * * *

"Although No. 360,070 was not declared upon in the earlier suit, it was discussed at great length and its meritoriousness was clearly recognized. The statement of the problem to be solved as it stood prior to January, 1888, and of the contribution of No. 360,070 to that solution, as they are set forth in the opinion above cited, leave no doubt that both the Circuit Court and the Circuit Court of Appeals regarded it as a patent of wide breadth."

Surely, in a case like the present, unless there be some controlling fact or principle of law which has been overlooked by all of the tribunals before whom this question has been in controversy, this is one of those cases of a "machine patent" in which, if the essential elements of the claims be found, the "special devices" set forth by the patentee "are not necessary constituents of the claim," and the rule of construction applicable to it "*is of a kindred character to that applied in this country and in England to a patent for a process*" (*Morley Co. vs. Lancaster*, 129 U. S., p. 263).

The Barbed Wire Case, 143 U. S., 275.

McCormick Co. vs. Aultman (C. C. A.), 69 F. R., 371, 386.

Second Point. *Nothing in the prior art impairs the scope of the Westinghouse claims.*

Having now shown that, as a practical matter, the invention of Westinghouse here in suit was of a primary or pioneer character, because :

1st. The *result* achieved was new.

2d. It has been largely, if not universally, adopted.

3d. The *means* for producing the result, not only in detail but in general character, were new (viz., venting train-pipe air into the brake cylinder for emergencies, and for emergencies *only*).

4th. The novelty, both in the source of the air pressure and the mechanical means controlling its introduction (the *double* traverse of the piston), was not only novel, but was startlingly and paradoxically so.

We now proceed to consider more in detail the line of inquiry to which our attention has been directed by this Court.

Was there anything in the state of the art, or in what Westinghouse himself had previously done, which impairs the substantial novelty of the invention?

Two, and only two, references are cited in Mr. Hill's brief as having any bearing upon this branch of the case. These are :

(a) The Westinghouse Patent No. 217,838, and

(b) An alleged English patent of one Sanders of 1879 (see Mr. Hill's Reargument Brief, pp. 91, 92).

Neither of these have any importance in limiting Westinghouse's present invention.

A brief explanation will make this apparent.

What was the problem which had been so long before the constructors of railway brake apparatus, and which was solved by the Westinghouse Patent in 1887?

The object sought was to stop a heavy and long freight train *both* in a shorter distance *and* with a quicker serial action from car to car.

This was not a simple problem.

It must be borne in mind that it is not permissible to ordinarily use brakes of such power as to actually stop the rotation of the wheels and cause them to slide upon the track.

While that action may be allowed in great emergencies, where everything must be sacrificed to safety, yet no brake is a practical one which in ordinary use ("service" use) will be liable to produce a sliding of the wheels.

The great disadvantage of the use of brake pressure so great as to produce wheel-sliding has been referred to even in *hand-brake* litigations which have been before this and other courts for the last forty years.

Mr. Westinghouse says (p. 115) :

"To render the operation of brakes, in 'service' stopping, satisfactory and economical, the result of practice has determined that the *amount of braking power should be limited to a degree that will render it possible to operate the brakes without reasonable liability*

of locking the car wheels when in motion. Such a result is objectionable, as by means of it flat spots are worn in the periphery of the wheels, and they are rendered unfit for further service."

(See discussion of this subject by Judge DRUMMOND, in 1863, in *Emigh vs. C., B. & O. R. R.*, 1 Biss., 400, and by Judge MORRIS, in 1881, in *Emigh vs. B. & O. R. R. Co.*, 4 Hughes, 271; and, indirectly, *Railway Co. vs. Sayles*, 97 U. S., p. 554.)

In 1887, however, air brakes had long superseded hand brakes. They were introduced by Mr. Westinghouse twenty years ago or more, and the maximum permissible pressure in the auxiliary reservoir had long been established by practice at seventy pounds. That pressure, *when expanded* into the brake cylinders, produces an effective braking force, for service use, of fifty pounds to the square inch (Newbury, Rec., p. 24, and p. 258, x-Q. 34). Long practice has shown that no greater power than fifty pounds in the brake cylinder can be used in ordinary service operations with satisfactory results.

Now, when the problem of equipping long and heavy freight trains with air-brakes presented itself, and when the question arose as to how such trains were to be stopped, not only *more smoothly*, but in a *shorter distance*, when emergency application was required, the question presented itself of devising a brake which for "service" use *would not* and *could not* exert greater pressure than before, but which should have a capacity *in emergencies only* of acting quicker and with greater power.

As was said by this Court in *Consolidated Valve Co. vs. Crosby Co.*, 113 U. S., page 157:

"This was a problem of the reconciliation of antagonisms, which so often recurs in mechanics, and without which practically successful results are not attained."

The *ideal* brake system might have been understood to be one which should include two separate and distinct brakes; one, a brake of limited maximum power and gentle or moderate application, which would serve all the purposes of every-day operations without injury to the wheels and without jolt or discomfort to the passengers or lading; the other, a brake of materially greater maximum power and of sudden and violent application, held in reserve for use

only in cases of threatened disaster, whereby the train could be brought to a stop in the shortest possible distance. Mr. Westinghouse says on page 124 :

" In fact, theoretical considerations would suggest *two independent brakes of different degrees of power or force* ; one of them to be used *for service operations*, to be *limited in power* to a point that would render the locking of car wheels impossible ; the other to be used only *in emergency or quick stops*, and calculated *to exert a much greater force*, thereby overcoming the speed of the train *in the least possible time and distance*."

It was fully recognized by practical railroad men, however, that the difficulties and complications connected with the employment of *two different* brake systems upon the same train were practically insurmountable and prohibitory, and no attempt was therefore made to realize the advantages of such a double system.

It was suggested on the prior argument of this case, in this Court, that greater power might have been secured either by enlarging the auxiliary reservoir under each car, or by storing it with air under higher pressure, or by enlarging the brake cylinder, so as to apply pressure on a larger piston area.

These suggestions were made outside of the proofs, as there is nothing in the record to show that either of these expedients would meet the conditions which confronted the art.

As a matter of fact, consideration of each of these suggested solutions (and for this we must also go outside the record) will show that neither of them can possibly be practicable.

Increased auxiliary reservoir capacity and increased auxiliary reservoir pressure would necessarily increase the power applied at each full "service" application of the brakes, as well as in "quick action." Whatever the maximum brake cylinder pressure may be, *it is the fixed maximum for both service and emergency applications*. But increased pressure is not permissible in service use, without danger of wheel-sliding. If greater pressure were sought for and availed of in *emergency* application by enlargement of the auxiliary reservoir, such greater pressure would also be present in every full *service* application. This,

for the reasons above explained, is impracticable. The limit of pressure to be exerted in *service* applications had been fixed by probably more than twenty years of practice.

Nor would the expedient of enlarging the brake cylinder, so as to increase the area of pressure on the piston, be any more available. A large cylinder is one which, with a given inlet, fills more slowly, just in proportion to its size. A brake, therefore, which would be more powerful because of increased cylinder capacity, would be one which would be *too slow* in application.

Neither one, therefore, of the suggested expedients for solving the problem could, in the nature of things, have been possibly availed of, and there is no hint in the proofs that either of these suggested solutions was ever attempted, either before or since Westinghouse's invention of the patent in suit. In fact, for the reasons above given, they are wholly impracticable.

The problem was how to get quicker action and increased efficiency *with the same reservoir power*—the latter having already reached the maximum limit.

What was Westinghouse's solution?

As above noted, it was of a "startling and paradoxical nature." He did not produce two separate brake systems, but he made a *unitary contrivance with the functions and advantages of two*, and with *none of the complications* involved in the use of two.

He kept the automatic brake, so far as its "service" use was concerned (whether for full stopping or for graduating speed), absolutely intact in every function and mode of operation. It could be applied delicately or with full pressure at will, but it never exceeded the limit of practicable pressure (50 pounds to the square inch in the brake cylinder), without the distinct volition of the engineer in specially manipulating his valve at the engine.

But when an emergency arose, when the train was to be stopped at all hazards and in the shortest possible distance, and when wheel-sliding, with its attendant impairment of the rolling-stock, became of secondary importance, then the engineer possessed the power, and the apparatus which Westinghouse invented possessed

the new capacity of quicker and more powerful action, by the mere throwing wide and suddenly open the engineer's valve, and suddenly reducing the pressure in the train pipe by twenty pounds. By that means, a new port was opened and the air, at reduced pressure, was admitted through a larger aperture into the brake cylinder, thereby *rapidly* filling it, and thereby diminishing the space into which the auxiliary reservoir air, at its higher pressure, had to flow and expand, and thereby, by the use of *both* train pipe and auxiliary reservoir air, the brake cylinder was filled more quickly and with air at a higher pressure (because less reduced by expansion), and, by this same venting of the train-pipe air into the brake cylinder, he *also* simultaneously produced *quicken*ed serial action from car to car (*Newbury*, pp. 257-8, 9, 345 and 346; *Newbury*, p. 23; *Boyd*en, p. 657; *Westinghouse*, p. 124).

We submit that the invention which solved this great and complicated problem, produced this highly useful result, and produced it by such unexpected means, is entitled to every favorable construction which the rules of law permit.

Well did Judge MORRIS say of the prior art (*Record*, p. 847) :

"The problem was not solved; indeed, the first step in the direction of solving it does not appear to have been taken until the experiments which led to the Westinghouse Patent now in suit. The substance of the method then devised is the use of the sudden further traverse of the triple valve piston to open a valve in a manner different from the valve opening made by the preliminary traverse for service braking, thereby admitting train-pipe air to the brake cylinder without its passing through the auxiliary reservoir."

And again (p. 843) :

"The result which Westinghouse was seeking in the new device, described in Patent No. 360,070, was first and principally to vent the train-pipe air at each car so as to quicken the serial action of the brakes from car to car; and, secondarily, to utilize the vented air and not waste its power."

And the Court of Appeals described the object which Westinghouse (first) and the defendants (subsequently) attained in the following words (p. 875) :

"the *common object* being to produce a mechanism by which to secure instantaneously, whenever and *only* when a sudden emer-

gency arose, *such a quickened discharge of compressed air into the several brake-cylinders that each car would simultaneously, and the entire train as a whole, be brought to a sudden halt, but leaving the mechanism already existing for use in ordinary braking unmolested and unchanged.*"

Having thus explained the problem, let us now consider the references relied upon to impair the merit of Westinghouse's "quick-action" invention.

(a) *The Westinghouse Patent No. 217,838 (Record, p. 759).*

This patent undoubtedly suggests the desirability of quick serial action, and makes the statement that, to accomplish this, "it is only necessary to make provision for the simultaneous opening of one or more ports in the air-conduit passages at points not remote from each auxiliary reservoir."

The patent then says :

"For this purpose I arrange at such various parts of the air-conduit or communicating pipes as may be desired, but by preference at the couplings, relief valves of the kind shown in the drawings."

The trouble with this patent and its availability to the defense, in seeking to limit the scope of Westinghouse's claim, is that the patentee had only *half* conceived the problem, and did not provide a practical means for carrying out even that half which he had conceived.

He *thought* that it was "*only* necessary to make provision for the simultaneous opening of one or more ports in the air-conduit passages at points not remote from each auxiliary reservoir," and to do this by means of a "relief valve," such as he described and illustrated.

He was wholly in error even in this partial conception. "Only" doing what he described is valueless.

That way of dealing with the problem does not solve it.

Indeed, Mr. Boyden himself (the principal expert for the defendants) admitted this.

Boyden obtained permission from the Court to test certain valves (Rec., p. 663), and he thereupon tested, in presence of complainant's experts, certain valves which he *claimed* were like

those of Patent No. 217,838, but which he had to admit (Record, pp. 685-690) were *modified* in some particulars, not found in the patent nor apparent from the prior art (p. 685, x-Qs. 301-305).

And he then was compelled to admit (Rec., p. 692) as follows :

" 344 x-Q. Did the tests which you made with the device of Patent 217,838 demonstrate that said device was in any wise practically operative to admit air from the auxiliary reservoir to the brake cylinder by preliminary traverse of the triple-valve piston, and to admit air directly from the main air pipe to the brake cylinder by a further traverse of the triple-valve piston ?

" A. They did not.

" 345 x-Q. Did the tests which you made with the device of Patent 217,838 demonstrate that said device was practically operative to a degree sufficient to warrant you or any other capable air-brake constructor in advising its adoption in practical railway service ?

" A. The tests demonstrated that the device would quicken the action of the brakes ; and they demonstrated to my mind, as I think they would to any one who is skilled in air brakes, that the device of Patent 217,838 could be so arranged and modified to suit the automatic air brake as to make it just as efficient a brake as those now in general use, and one that could be recommended to railroad officials for practical use.

" 346 x-Q. (x-Q. 345 repeated.)

" A. The results produced by the devices of Patent 217,838, *as I tried them*, were not of an efficiency that would justify me in recommending the use of the devices to railroad officials.

" 347 x-Q. Did the tests which you made with the device of Patent 217,838 demonstrate that said device was practically operative to such a degree as to lead you to believe that it would be acceptable to, and accepted by, any competent railroad official for use in practical railroad air-brake service ?

" A. The tests I made with the device of Patent 217,838 demonstrates that the device, as I made them, was not practically operative to be used in service ; but they demonstrated that the device of Patent 217,838 *could be so modified* that it would practically be operative in railroad service. As to being able to get railroad officials to adopt it, that is something I cannot say, as I might be able, then again I might not."

And again (x-Q. 348) :

" A. My opinion is that the device, *as I used it*, would not be acceptable to railroad officials for practical use."

This Court, in *Topliff vs. Topliff*, 145 U. S., page 156, emphatically condemned any such method of endeavoring to anticipate a patent by "modifying" prior contrivances, saying :

"It is not sufficient to constitute anticipation that the device

relied upon might, by a modification, be made to accomplish the function performed by the patent in question, if it were not designed by its maker, nor adapted, nor actually used, for the performance of such functions."

Rebuttal to such evidence was hardly required, but, on the part of the complainant, Mr. Newbury testified on the subject of the operativeness of valve of No. 217,838, as follows (p. 189, Q. 223) :

"A. So far as I can see, the device of the said patent 217,838 is not adapted at all for practical operation in an automatic air-brake system, or, in other words, an attempt to incorporate such mechanism in an automatic air-brake system would simply destroy it and render it utterly worthless as such a system.

"Furthermore, the device shown and described in said patent 217,838 is wholly incapable for any practical use, unless it can be said that the destroying of an automatic air-brake system was practical use, as that is the only purpose which I can see that it would serve."

He then proceeds to give the reasons for this statement, which are wholly uncontradicted.

And Mr. Barnes (p. 405, Q. 699) said :

"A. It is not at all applicable, for the plain reason that it could not be used practically. Such a device so obstructs the feeding or charging process as to prevent its practical application to practical trains.

"It would be impossible to graduate the brakes in a service application, so as to make the necessary difference in the force of applying the brakes."

He then proceeds to give the reasons for these statements.

Mr. Westinghouse says (p. 830) :

"I did not find the devices made by Mr. Boyden to be in strict accordance with the instructions of patent 217,838, but, on the contrary, there were important and wide variations in those structures."

And again (p. 830) :

"A. I have been unable to find anything in the specification or drawings of the patent in question that would justify any departure from the usual practice of a skilled mechanic, in making a structure from the said drawings and specification."

And again (p. 834, Q. 904) :

"904 Q. Taking the valve device as you saw it experimented with, as changed and modified by Mr. Boyden in the particulars you have stated, and in view of the results produced by Mr. Boyden, what is your opinion as to the practical merit or value of said valve device for actual use in controlling freight trains on railroads?

"A. I agree with the opinion expressed by Mr. Boyden in answer to x-Q. 348, that the device, as he used it, would not be acceptable to railroad officials for practical use.

"905 Q. To what extent, if at all, would your opinion be modified if the valve device was constructed in strict accordance with Patent No. 217,838, instead of deviating therefrom, as used by Mr. Boyden, in the particulars you have specified?

"A. Not in any respect.

"906 Q. Mr. Boyden admits, in answer to x-Q. 305, that it is the fact that, long prior to the institution of this suit, he himself recognized the obvious practical inoperativeness of the device of Patent 217,838. To what extent do you concur on Mr. Boyden's recognition of the obvious practical inoperativeness of this device?

"A. I fully concur with him."

As to Patent No. 217,838, at least, therefore, the Court of Appeals and Judge MORRIS were entirely correct in their finding, viz., that it did not in any way solve the problem involved in "quick action"—*i. e.*, "quick action" serially and individually for emergency use, and unimpaired "service" action—and the more so because the proofs on both sides are to that effect.

(b) *The alleged English Patent of one Sanders, of 1879.*

Mr. Hill's brief of reargument contains the assertion (p. 91, foot of page):

"The fundamental law shown in the 1879 patent to Mr. Westinghouse was not first disclosed by him, as it was patented in England (R., p. 68, line 7), March 12, 1879, No. 980, by Sanders."

This is a somewhat unusual statement, for no patent to Sanders is in the record, either of March 12, 1879, or of any other date. Mr. Hill's reference to the record, at page 68, contains no mention of any patent to Sanders.* All that appears at the place in the record referred to is a statement by Mr. Newbury that a certain combination of devices, *not* organized to produce "quick action," but for some other different purpose, is found in "British Letters Patent of about the year 1879."

* Although there is no patent of Sanders in the record, we have no objection to saying that a Sanders Patent exists, although we should expect to show, if opportunity offered, that it is not like Westinghouse's, and that it has been fully considered and overruled in other litigations.

Of course it should not have been referred to (*Preston vs. Prather*, 137 U. S., 604).

There is in the record a British Patent of 1879 to Barker (Record, p. 473), and to this, doubtless, Mr. Newbury referred. This patent shows an automatic air-brake mechanism, with the elements named in the questions to Mr. Newbury, but *not so* organized and arranged as by any possibility to produce "quick action," and no one pretends that that apparatus has, or could have, any such effect. No one on behalf of the defendants so contends. The purpose and operation of the Barker apparatus is fully explained on page 476 of the record, and is an entirely different one.

We may conclude, then, in answer to the first branch of the inquiry suggested by this Court, that there is nothing in the state of the art, including the patents to Westinghouse, which impairs the scope of the patent in suit.

Third Point. *We next inquire whether the proceedings in the Patent Office have any effect in limiting the scope of the patent in suit.*

What were the proceedings in the Patent Office?

They appear by the file wrapper of his original application (Record, p. 714).

The patentee presented as the form of his first claim the following :

" 1. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake cylinder and a triple valve provided with a device for admitting air directly from the main air pipe to the brake cylinder, substantially as set forth."

The second claim was originally presented in the precise form in which it was finally patented as follows :

" 2. In a brake mechanism, the combination of a main air pipe, an auxiliary reservoir, a brake cylinder, and a triple valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake cylinder, and which, by a further traverse, admits air directly from the main air pipe to the brake cylinder, substantially as set forth."

The Patent Office, on January 14, 1887 (Record, p. 717), alleged that claims 1 and 2 were anticipated by the Boyden Patent No. 280,285, of 1883.

The patentee thereupon, under date of January 19, 1887 (Rec-

ord, pp. 717, 719), amended his first claim to the form in which it was patented, retaining the second claim unaltered, and filed an argument showing that the Boyden invention had nothing whatever to do with the problem of "quick-action."

The claims were subsequently allowed.

When it is remembered, as Judge MORRIS said (Rec., p. 849), "*what was the real invention*," it will be apparent that the amended first claim, which Westinghouse filed as substitute for that first presented, had no limiting effect upon the scope of the patent, and certainly had none upon the second claim, *which was not altered at all*.

The gist of the invention lay in the combination by which the triple valve, *with all of its functions for service use retained*, was supplemented by a port, controlled by the triple-valve piston which in emergency use (and *only* then) was opened for the admission of train-pipe air to the brake cylinder to produce "quick action."

The first claim of the patent, *as originally presented*, did not "particularly point out," as the statute required (R. S., Sec. 4888), this fundamental feature of the invention. It was so phrased as *seemingly* to include an apparatus which was "provided with a (*i. e.*, any) device for admitting air directly from the main air pipe to the brake cylinder," irrespective of the purposes and conditions by and under which said admission was effected.

Hence the Boyden Patent of 1883 was cited by the Patent Office, not because that patent describes a "quick action" brake, nor one which has the remotest effect in limiting the *real* invention of Westinghouse, but solely because it happened to have a passage from train pipe to cylinder in a *different* combination and for an entirely *different purpose*, to wit (p. 776): "for replenishing, *while the brake is on*, the air reservoir on each car, or the brake cylinder when the pressure therein has been *lessened by leakage*."

Now, nothing could be more unlike Westinghouse's "quick action" apparatus in operation, purpose and result than this device of Boyden's.

Hence the attorney, when the inaccuracy of the original wording had been pointed out, amended the first claim so as to clearly distinguish Westinghouse's apparatus from that of Boyden's of 1883, and satisfied the Patent Office that the Boyden apparatus of 1883 had no pertinency whatever in connection with the second claim, which was thereupon allowed.

That the Boyden Patent of 1883 had no relation to "quick action" is admitted by Boyden himself. He said (Record, p. 497, Q. 8) :

"I wish to state here that my 1883 patent was not for a 'quick-action' valve (as that term is now understood)."

And, again (Record, p. 574, x-Q. 195) :

"In the triple valve of Patent 280,285 *no application whatever* of the brakes is effected by the passage of main air pipe air to the brake cylinder, and no main air pipe air is admitted to the brake cylinder until *after* the brakes have been applied, with the maximum rapidity and force within the capacity of the device, *by auxiliary reservoir air alone.*"

And again, on cross-examination, he says :

"I did not wish to imply, nor do I now, that my 1883 patent was for a quick-action valve such as you have stated."

Judge MORRIS found, as a matter of fact, that, as between the Boyden Patent of 1883 and the patent in suit,

"There seems to be no analogy or comparison that can be made between them."

And this ruling was not disturbed by the Court of Appeals.

In the matter of amending the *claims*, there was, therefore, no limitation of the scope of the real invention, but only a more clearly defined statement of that invention as compared with one which had no real relation to it.

The terms of a patent claim are in the nature of the metes and bounds of a deed for land, in that they define the limits of the grant. If the metes and bounds of an original deed, or of an application for a land grant, include more than the grantor could give, and more than the grantee intended to ask for, the metes and bounds must be corrected and limited, but—and this is the rule the benefit of which we invoke—*everything within the corrected metes and bounds belongs to the grantee.*

In formulating the amended first claim all the metes and bounds remained as before, unaltered and unchanged, except one. For "a device," of any kind—which gave a boundary line of too large an extent because it included something which was not "Quick Action"—there was substituted, as respects *that* claim, a new boundary line, which is thus defined:

"an auxiliary valve device, actuated by the piston of the triple valve, and independent of the main valve thereof."

We have shown, as we believe, in our original brief (pp. 38-79), that defendants' quick-action apparatus comes inside or within the correctly stated boundary line thus delineated.

Its "auxiliary valve device" is the valve 22. It is "actuated by the piston (29) of the triple valve," and is "independent of the main valve"—a "*service*" valve, *i j k*.

(For further discussion of this point see our original brief, pp. 91, 92.)

Another amendment to the specification was that embodied in the amendment of January 19, 1887 (Record, p. 720). In that amendment applicant stated as follows:

"I am aware that a construction in which 'an always open one-way passage' from the main air pipe to the brake cylinder is uncovered by the piston of the triple valve simultaneously with the opening of the passage from the auxiliary reservoir to the brake cylinder has been heretofore proposed."

He thereupon disclaimed that construction as one which involved an operation different from that of his invention.

This "disclaimer" was rather in the nature of an *explanation* than a true disclaimer. It pointed out that the use of an "always open one-way" passage was an entirely different thing from the patentee's construction, in which the passage or port from the train pipe to brake cylinder is *not* "always open one way," but is never open operatively except when it is forcibly opened for an emergency application of the brakes.

Surely here was no limitation of the real invention, nor any impairment of the proper scope of the claims.

The defendants' port under valve 22 is *not* "always open," but is open (at least for effective purposes) *only* in emergencies.

Nor was the argument of the applicant's attorney (Record, pp. 718, 819) one which can be used in the interest of an infringer to narrow the scope of the claims. The whole purpose of that argument was a simple and a single one. It was intended to point out that the Boyden Patent of 1883 had no relevancy whatever to the real invention of Westinghouse, and such was the fact, as it is now conceded by Mr. Boyden.

This Court will not, we believe, impair the just scope and control of the claims for a valuable invention, on any strained construction of the phraseology of the attorney for the applicant, used in the course of showing how totally different Westinghouse's invention was to that of the prior Boyden Patent, which, it is admitted, taught nothing on the subject of "quick action."

In *Societe Anonyme, &c., vs. Rehfus*, 75 F. R., p. 657, Judge ACHESON said :

"That the patent office imposed, and the applicant accepted, the limitation upon which the defendants insist, would be a strained conclusion. *An estoppel is not to be implied from circumstances of doubtful import.* This is a fundamental invention, and, upon well-considered principles, the patentee and his assignees would have the benefit of the doctrine of equivalents in large measure. Looking at the entire proceedings upon Cleret's application, it cannot, I think, fairly be said that either the patent office, on the one side, or the applicant, on the other side, contemplated a limitation which would render the claims practically valueless, and make the grant of the patent a vain thing. Let a decree in favor of the plaintiff in each case be drawn."

In *McCormick vs. Aultman*, 69 F. R., p. 371, the Circuit Court of Appeals (Judge TAFT, delivering the opinion) said (p. 393) of the facts which should limit a pioneer patent, as follows :

"*Nothing* will restrict the pioneer patentee's rights in this regard save the use of language in his specifications and claims which permits *no other reasonable construction* than one attributing to the patentee a positive intention to limit the scope of his invention in some particular to the exact form of the device he shows, and a consequent willingness to abandon to the public any other form should it be adopted and prove useful."

Only one other change in the original application was made. Mr. Westinghouse in his original specifications stated the *fact* that

the valve, which, on being opened, gave *emergency* action, instead of being made *separate* from the main valve of the triple, might be made "integral" herewith, and be "formed by an extension thereof." This is so obviously a mechanical equivalent that the statement of the fact would seem to have been useless and superfluous. But as he did not illustrate this particular modification in his drawing, the Patent Office told him that he must either illustrate it or erase this brief reference to it—such being the Patent Office rule at that time (Hogan, Rec., p. 277). He erased it. This is the whole story. But by no rule of law ever yet enunciated can it be held that the erasure of a description of a mechanical equivalent operates as a disclaimer of such mechanical equivalent. The patentee is always entitled to the full benefit of the doctrine of mechanical equivalents, so far as it may apply, whether he describes them or not. The law gives them to him anyhow.

Winans vs. Demead, 15 How., 330, 342.

Goodyear Co. vs. Davis, 102 U. S., 222, 230.

Clough vs. Barker, 106 U. S., 166, 177, 178.

[See cases cited in our original brief, p. 98, and those above quoted.]

But again, this erasure, no matter whether it had the effect of a disclaimer or not, is irrelevant to the present case, for the reason that the defendants' *emergency* valve 22 is *not* made "integral" with the *service* or "main" valve *i, j, k* of its triple valve. Hence, in any view of the case, defendants' apparatus comes within the metes and bounds of the grant made to Westinghouse in and by the patent in suit.

As to the Patent Office action in granting patents to Boyden, *pending the suit*, such action amounts merely to a Patent Office decision that Boyden had made some patentable improvements on Westinghouse, but the Patent Office has under Act of Congress no jurisdiction of the question as to whether these additional improvements *actually contained* the prior Westinghouse invention. That question, under Act of Congress, belongs to the courts. In fact, the

Patent Office has never even presumed to adjudicate questions of that kind, and even if it had, its action would be *ultra vires* and void.

What is said in the Boyden specifications on this point are nothing more than the voluntary *ex parte* statements of Boyden or his counsel, put in writing and printed at the expense of the United States. The Patent Office had no authority under the law to determine whether such statements were true or not, and therefore no presumption arises from the issue of the Boyden Patents as to whether they are true or not.

[For the law here applicable see cases cited in original brief, pp. 98-100.]

Fourth Point. The final point suggested by the Court now presents itself.

We have shown that nothing in the prior art, nor in the proceedings in the Patent Office, tend to limit the scope of the Westinghouse invention, and the claims which purport to cover it, so as to make inapplicable to them the beneficial rule announced by this Court—that, in the case of pioneer patents, rules of construction are to be adopted analogous to those which prevail in the case of process patents.

We now inquire, are the terms of the Westinghouse claims themselves of a character to admit of the application of this rule?

We respectfully submit that they are.

Westinghouse's first claim calls for the combination with the train-pipe, auxiliary reservoir, brake cylinder, and a triple valve of any of the forms of the old automatic brake apparatus (*Westinghouse says in the patent in suit (Rec., p. 788, line 18) that there were "numerous examples in the art of constructions varying materially in appearance"*), of an "auxiliary valve device" actuated by the piston of the triple valve, and independent of the main valve, for admitting air to apply the brakes, directly from the train pipe to the brake cylinder.

The second claim (specifying the invention, as it correctly may, from another point of view) particularly points out as the invention of the patentee the use (in combination with *any* of the numerous forms of automatic triple-valve brake mechanism) of the "preliminary traverse" of a triple-valve piston to admit air from the auxiliary reservoir to the brake cylinder, and of the "further traverse" of the triple-valve piston *to admit air from the train pipe to the brake cylinder*.

Whether the described intermediate connecting parts are or are not the same is of course immaterial (*Winona Co. vs. Deering*, 155 U. S., 285).

The first claim differs from the second in that it does not *require* a piston with a *double* traverse to be used (the specification suggests a "series of pistons" (Rec., p. 788, l. 17) instead of one), but defines the invention as residing in the use of a valve ["auxiliary" to the main (or "service") valve] for opening the port from the *train pipe* to the brake cylinder.

The second claim defines the invention by another of its important characteristics, to wit, that the triple valve piston is one which has a *double traverse*, and that the preliminary traverse is operative to control the admission of air from the auxiliary reservoir to the brake cylinder, and the further traverse is operative to control the admission of air from the train pipe to the brake cylinder.

The second claim, although literally a claim for a mechanical combination, is yet so phrased as to clearly entitle it to the liberality of scope accorded in analogy to the rule applied to process patents.

In a process patent the claim describes a certain action as taking place and producing a stated result, and the claim is valid to that extent and "irrespective of the particular form of the instrumentalities used" by which the action is effected and the result is produced (*Cochrane vs. Decner*, 95 U. S., 780).

In Westinghouse's second claim the gist of the invention is stated in the sentence which describes the triple-valve piston as acting by its preliminary traverse to open a passage from auxiliary reservoir to brake cylinder, and by its further traverse to open a

passage from train-pipe to brake cylinder. Now, such actions can only take place *by the opening of ports and passages* from the respective sources of air pressure to the brake cylinder, and hence (as pointed out in our supplemental brief, p. 27) such claim is equivalent to the following, viz.:

2. In a brake mechanism the combination of a main air pipe (train pipe), an auxiliary reservoir, a brake-cylinder and a triple valve having a piston whose preliminary traverse (*by opening a port*) admits air from the auxiliary reservoir to the brake-cylinder, and which, by a further traverse (*by opening a port*), admits air directly from the main air pipe (train pipe) to the brake-cylinder, substantially as set forth.

But under *such* a claim, relating to *such* an invention, the *particular valves* and the *particular passageways* are "not necessary constituents of the claim" (*Lancaster Co. vs. Morley, supra*) any more than the particular mechanism for effecting a specified step of a new process is essential to the infringement of that process.

The Telephone Case, 126 U. S., 1.

New Process Co. vs. Maus, 122 U. S., 413.

We submit, then, that the phraseology of the claims themselves, and particularly of the second claim, is such as to entitle the complainant to invoke the rule and breadth of construction analogous to that prevailing in the case of process patents; and this is also true, although the claim be construed strictly as a mechanical combination.

In *McCormick Harvesting Machine Co. vs. Aultman*, 69 F. R., 371, the Circuit Court of Appeals for the Sixth Circuit said (p. 387) (following the Court in *Lancaster vs. Morley*):

"With respect to such a patent, the well-established rule is that the patentee who has, by the success of his patent, pointed out the combination of functions needed to reach the new result, and has claimed the combination of mechanical parts performing those functions, may enjoin the use of another machine producing the same result where the second machine differs from the first only in a substitution, for parts or elements of the patented device, of parts or elements which, though different in form and kind, perform the same functions in substantially the same way. It may be that the substituted parts are well-known equivalents of those shown in the patent for the performance of the functions to which they are respectively applied, in which case there is manifestly no inventive

faculty shown in the change, or it may be that, being shown by the successful operation of the patent the exact nature of the functions to be performed by a part of the patented device, the infringer, by the use of his inventive faculty, hits upon something as a substitute which will perform the same functions more completely and satisfactorily. In the latter case, he is a tributary inventor, but he is none the less an infringer if he uses the whole machine, with his substituted part to accomplish the same new result. The rule as to infringements of pioneer inventions which point the way to new products or results is analogous to that applied in cases of infringements of process patents, in which the discoverer is only required to point out one practical method of using his process, and is permitted to claim tribute from all who thereafter use the process, whether with his apparatus or with a different or improved means."

Westinghouse's first and second claims, because the general purpose and function of the structure as a whole was new, are entitled to such a construction, that if the defendants' general purpose be the same as his, and the separate purposes and operations of the separate parts of their combination be also the same, then infringement is established.

This is the rule laid down by this Court in *Cochrane vs. Deener*, 94 U. S., 780, in connection with Cochrane's Patents, not only for his process, but also for his *apparatus*, for purifying middlings of flour (Reissue No. 6594).

That case has some features of marked similarity to the present one in the fact that the apparatus was one whose method of operation "underlay" a revolution in the art of making purified flour "middlings," and in the fact that the form of apparatus described by the patentee had been greatly improved upon (and in *that* case by the defendants themselves, while in this case by Westinghouse himself); and in the fact that the generic claim for the apparatus first advanced by the patentee (and in *that* case granted) had been subsequently amended and restricted to the actual invention (in *that* case by reissue).

Yet, notwithstanding all this, this Court said :

"The first claim of Reissue No. 6594 is for the collecting air chamber (used for the purpose aforesaid), in combination with the bolter, air pipes and valves for feeding and delivering the meal without allowing the air to pass therewith. Now, although the

defendants use a flat bolter instead of a reel, and use different kind of valves for feeding and delivering the meal without allowing the air to pass, yet they employ the combination of devices described in this claim. They use the collecting chamber *for the same purpose* as that pointed out in the patent, and use it in connection with bolter, air pipes and valves for feeding and delivering the meal without allowing the air to pass therewith, *each effecting the same separate purpose, and all combined effecting the same general purpose*, which the like parts are intended to accomplish in Cochrane's bolting apparatus. Though some of the corresponding parts of the machinery designated in this combination are not the same in point of form in the two bolting apparatuses, and, *separately considered, could not be regarded as identical or conflicting*, yet, having the same purpose in the combination, and effecting that purpose in substantially the same manner, they are the equivalents of each other in that regard. The claim of the patent is *not confined to any particular form of apparatus*, but (in regard to the valves, for example) embraces generally any valves for feeding and delivering the meal without allowing the air to pass through. We are of opinion, therefore, that the combination here claimed is infringed by the apparatus used by the defendants.

"It is unnecessary to make a separate examination of the other claims embraced in the two patents under consideration. They are all susceptible of the same observations which we have made with regard to the first claim. In our opinion, the defendants do infringe them."

Such is the case here.

The defendants manufacture and sell a brake mechanism (shown in its three positions in Drawing 14 opposite), which combines a train pipe, auxiliary reservoir, brake cylinder and a triple valve. The piston of this triple valve controls two valves (and their ports) for admitting air to the brake cylinder, one (the slide valve, with its port *i j k*) for admitting air from the auxiliary reservoir for most (if not *all*) "service" uses, and the other (valve 22), or "auxiliary" valve for admitting train-pipe air for emergency use. The purpose and object of their structure is admittedly identical with that of Westinghouse's patent. Also the separate purposes and functions and operations of the corresponding parts of defendants' device are the same as those of Westinghouse.

The preliminary traverse of the defendants' piston controls and opens the first-mentioned or "service" valve (slide valve *i j k*), and the "further traverse" of the piston controls and opens the second or "emergency" valve (valve 22).

To Auxiliary
Reservoir.

14—Release (Brakes Off).

To Auxiliary
Reservoir.

14—Service Application.

To Auxiliary
Reservoir.

14—Quick Action.

10—Release (Brakes Off).

To Auxiliary

To Train Pipe.

10—Service Application.

To Auxiliary
Reservoir.

To Brake
Cylinder.

To Train Pipe.

10—Quick Action.

To Auxiliary
Reservoir.

To Brake
Cylinder.

To Train Pipe.

This is the identical action of Westinghouse.

Thus we have a clear case of infringement within the rule laid down in *Cochrane vs. Deener*, in that the "general purpose" of the whole combination of devices is the same as that of the patentee's, and the "separate purpose" of the separate parts is the same as the like parts of the patentee's device, and the purpose in each is effected "in substantially the same manner;" and this constitutes infringement in the case of a pioneer patent, although some of the corresponding parts of the machinery "are not the same in point of form," and, "separately considered, would not be regarded as identical or conflicting."

We have shown, in our prior briefs (Principal Brief, pp. 60-69; Supplemental Brief, pp. 6-14), by a careful analysis of the separate features of the defendants' valves, that even upon a narrower construction of Westinghouse's claims, the defendants' devices are clearly equivalents to his.

They have built (as we have there shown) upon one old form of Westinghouse triple valve (Patent No. 141,685) instead of upon his other form of triple valve (Patent No. 220,556) and have reversed the position of some parts, and altered the form of others. Defendants' piston, by its further traverse, *pulls* the emergency valve (valve 22) off its seat, while Westinghouse *pushes* a valve off, by a like motion. But, under clever disguises, all of Westinghouse's parts are to be seen, and every function and mode of operation is accomplished.

This will be clearly apparent from a careful comparison of the Drawing 14 of defendants' valve with drawing of Westinghouse 10 on the opposite page (see analysis in Principal Brief, pp. 64, 65).

No matter, then, how the separate parts may differ in form from those of Westinghouse, and no matter whether the valves, as valves, may be "poppet" valves instead of "slide" valves, or *vice versa*; and no matter whether the passage for train-pipe air be *through* the piston and case of the triple-valve, instead of *at the side of it*. The general purpose of the mechanism, as a whole, is the same, and is effected in substantially the same manner, and the separate

purpose of each separate part with reference to the others is also the same (even although they may have some additional functions also); and infringement of such a patent as that of Westinghouse is, therefore, clearly demonstrated.

As was said by the Circuit Court of Appeals (9th Circuit) in *Von Schindt vs. Bowers* (80 F. R., 121, 148):

"The record shows that the complainant was the first to combine these elements at all, and that the functions performed by his machine so constructed were entirely new. Hence, he had the right to make the broad and generic claim [embodied in Claim 10] without any limitation as to the form of construction of the particular elements, and all subsequent machines which employ substantially the same means to accomplish the same result are infringements, notwithstanding the subsequent machine may contain improvements in separate mechanism which go to make up the machine."

In the foregoing discussion we have endeavored to follow the lines indicated in the memorandum of this Court of January 24, but we also submit that, even upon much more rigid principles of construction of the patent in suit, infringement is clearly established.

In our former briefs we have dealt, we believe, with each and all of the positions advanced by the defendants, and we hope that we have successfully controverted them; and we have shown, by a series of illustrative drawings, that each and every change of position or shape of parts which has been adopted by the defendants is a mere equivalent, and a known equivalent, for the corresponding part of the Westinghouse device.

In our view "the purpose, principle and operation of the machines are the same" (*Consolidated Cable Co. vs. Pacific Cable Co.*, 53 F. R., p. 385), and the patent in suit is entitled, by virtue of the revolution which it has wrought, and the benefits which it has conferred, to such a "comprehensive construction" (*Norton vs. Wheaton*, 57 F. R., 927) as will fully and adequately protect the inventor and his assignees.

Respectfully submitted,

GEORGE H. CHRISTY.

FREDERIC H. BETTS,

Counsel for Respondents.

Errors in Appellee's Brief on Second Argument.

Outside of errors of argument, the Boyden brief, on reargument, contains numerous errors of incidental statement or recital, a few of which may be briefly noted.

1st. Page 8, line 4, from bottom, denial is made that in defendants' triple valve, *train-pipe* air goes to the brake cylinder "through any separate and independent passageway."

This is erroneous. Defendants' quick-action triple valve has a "separate and independent passageway," F, *through the triple valve piston*, which is opened when and only when *train-pipe* air is to be admitted to the brake cylinder for purposes of quick action (see lower drawing, facing p. 40 of first Westinghouse brief).

2d. Page 10, lines 2-7, do not correctly state the Commissioner's duty in the case in hand. When Boyden's later application was properly filed, all the Commissioner had to do was to determine whether the *particular combinations* of the claims so submitted were to be found in the prior art. Whether those *particular combinations* were based on or included the subject matter of inventions previously patented to somebody else is a question which belongs to the Courts and not to the Commissioner, under Act of Congress. The Commissioner could not pass on that question, and if he did his action would be nugatory, as *ultra vires*.

3d. Page 18: It is represented that the apparatus of the patent in suit, "although it is an operative device," "did not meet the public demand," etc.

This is erroneous. It *did* meet the public demand, although, like all primary forms of invention, it was subsequently improved upon. Two thousand of them were made and sold and went into public use.

Westinghouse Rec., pp. 305, 306, x-Qs. 485, 486.

This charge has been repeatedly disposed of in every litigation, and the proofs on this subject and the decisions of the Courts thereon are fully dealt with in our principal brief (pp. 33-38). A

similar contention was advanced in the Circuit Court of Appeals for the Ninth Circuit in *Von Schmilt vs. Bowers*, 80 F. R., pp. 121-150.

In that case the Court said:

"The contention on the part of counsel for the appellant that no successful machine can be built and operated in accordance with the complainant's patents is not at all supported by the record, which contains abundant evidence to the effect that machines have been so built and have ever since been operated with very great success. The fact, if fact it be, that the first machine built by the complainant (called in the record the 'Davis machine') was not successful in its operation, is unimportant. As was well said by the Court, in answer to a similar objection in the case of *Mergenthaler Linotype Co. vs. Press Publishing Co.*, 57 F. R., 506:

"It would certainly be a novel doctrine to deny to an inventor the fruits of a broad invention because the machine which first embodied it was rudimentary in character and failed to do as good work as improved machines made subsequently. None of the great inventions could survive such a test."

To the same effect see *Cochrane vs. Deener*, 94 U. S., 780, 786-7.

4th. Page 21, line 5, by the words "*not because of any change in them*"—that is, in the old automatic triples—implies the assertion that Boyden in his present construction has adopted an old automatic triple *without any change therein*.

A valve 22, loose on its stem, so that it will *stay* on its seat during the *preliminary* movement of the triple-valve piston, as in service use, and will be unseated by the *further traverse* of the same piston, to admit air from a different source of pressure, as in quick-action use, is not found in any of the old automatic valves referred to. Making the stem itself into one valve, for one purpose, and a loose valve on the stem, for the other purpose, and operating it by the "further traverse" of the piston, was a "change" in matter of substance.

5th. The same error appears in the same page, lines 5 and 4 from the bottom, "without any material change therein."

6th. The entire argument of page 22 is misleading. Defendants' quick-action triple valve contains "*two [mechanically] separate and*

distinct machines" (just as much as Westinghouse's). The one consists of the triple piston, *in re* its preliminary traverse, opening the main-stem valve *i j k*, for "service" use; and the other consists of the piston, *in re* its further traverse, opening a separate and independent passageway F through the piston, and unseating an "additional" or an "auxiliary" valve 22, for venting train-pipe air directly to the brake cylinder in "quick action." The valve 22 and the passageway F are "additional members," and, in effect, constitute "another machine" as much as do the corresponding parts of Westinghouse.

7th. On page 24 an erroneous meaning is attributed to the word "*directly*." As this word is used by Westinghouse, it draws a distinction between the air which is *previously stored* in the auxiliary reservoir, and there held for use, and the air which is *not* so stored and held, but travels at once, or "*directly*," from train pipe to brake cylinder. Observing this distinction the word "*directly*" applies equally to the Westinghouse patented apparatus and to the Boyden infringing apparatus.

8th. "Reasoning by exclusion" (p. 25) is a method of reasoning which the Courts have never yet adopted in dealing with novel meritorious inventions.

9th. Lower on the same page (25) the allusion to "*mechanism integral therewith*" involves *apparently* an effort to get this Court to pass on an issue which does not arise in this case. Defendants' valve 22 is not "integral" with valve *i, j, k*. It is a different, and an "auxiliary" valve."

10th. The assumption that an erasure is always a disclaimer (p. 26) is not well founded in law. We have discussed this elsewhere.

11th. The "integral" issue, which, as already stated, is not involved in this case, is again made the basis of an effort at argument on page 27.

12th. We have never contended, and do not now contend, that "*remaining claims or any substituted claim*" shall receive "a construction or interpretation which shall be tantamount in scope and comprehensiveness to the original and erased statement and first claim" (B. brief, p. 28).

The original and erased first claim *in terms* covered the valve of the 1883 Boyden Patent. The present claims do not. And right there lies the distinction in respect of the proper legal construction of the claims as they now stand.

13th. The Circuit Judge did not assume that "such 'further' traverse was *per se* new" (p. 31). He found what was true, that it was new *in re* its work of *admitting train pipe air* to the brake cylinder.

14th. The "integral" issue is again worked in as the basis of the argument (p. 34).

15th. Assertion is again made (p. 35) that "defendants' device has no additional passageway at all," and no "auxiliary or other valve," etc.

We have already pointed out the passageway F through the triple piston is an "additional passageway," and that 22 is an "auxiliary" valve.

This error, repeated over and over again, runs through the entire Boyden brief, and it would unduly lengthen these notes to point it out wherever it occurs.

16th. It may be noted that the alleged analogies between *Gill vs. Wells* (pp. 43-54) and the case at bar are wholly suppositions. Infringement was denied in *Gill vs. Wells*, because (1st) the patent was not of a pioneer nature; (2d) the defendant "entirely omitted" an express element (guiding devices) of the patentee's claim *and used no equivalent*. Analogies are of but little force at best, and when *wholly imaginary* it is difficult to see how they can have any force at all.

17th. What is said of the lower drawings facing pages 64, 65, and entitled, "The Old Poppet Form of Triple Valve," *seems* to assert that a valve 22, *loosely* mounted on the stem (also made into a valve) of a triple-valve piston was old in the air brake art. *This is not true, nor is there any evidence in the case showing or tending to show that it is true.* Hence, the argument based thereon, and running through several following pages, is fallacious.

A poppet valve *fixedly secured* to the piston stem, so that the valve would open or close with *every* movement of the piston, was old, and constituted the main valve. When defendants made that valve *loose* on its stem, and so that it would be opened only by the "further traverse" of the piston, and made it "auxiliary" to the main valve *i, j, k* (or 40), it became an "auxiliary" quick-action valve, "additional" to the main valve, and, as such, it became mechanically and operatively "an additional member," operated by the "further traverse" of the piston, so as to open an additional passage F, directly from the train pipe to the brake cylinder—the passageway F thus being the other "additional member."

18th. The facts as to the presence in Westinghouse of what is in substance the partition 9, is presented in both of our prior briefs (Original, pp. 100-106 ; Supplemental, p. 12). Boyden is not the inventor of a *choke* for auxiliary reservoir pressure. That is in every quick-action valve ever made.

19th. The assertion (p. 79) that the Boyden piston "performs *only one* function" is not well founded. It performs *one* function during its preliminary traverse in that it opens the main valve *i, j, k* (40), the valve 22 then remaining on its seat. It performs *another* function when, in its "further traverse," it unseats the valve 22, which latter thereby acts as an "auxiliary" valve. The passageway F then opens, and the "new function" of the Westinghouse Patent is then performed.

20th. The effort (pp. 84, 85) to ally defendants' present appa-

ratus with that of the Boyden 1883 Patent ignores an important difference.

The passageway F in the present valve of defendants is not "*always open one way*." In "*service*" use it is *always closed*. Westinghouse disclaimed the former, but not the latter. Defendants' present valve contains the latter and not the former. The Boyden brief carefully ignores this important difference.

21st. "Differential pressures" between piston chamber and main valve chamber (pp. 85, 86) are of no importance. Both are small. The forces which *do the work* are *auxiliary reservoir* air and *train pipe* air. As between *these forces*, Westinghouse has the same differential pressures which Boyden has, and for the same purposes, and secured in the same way—by admitting *auxiliary reservoir* pressure through a *small* port, and *train-pipe* pressure through a *large* port. The Boyden brief admits as much when it says (p. 85, near bottom): "Of course, all triple valves in operating must have differential pressure."

No. 116.

GEORGE WESTINGHOUSE, JR., ET AL., APPELLANTS,

vs.

BOYDEN POWER BRAKE COMPANY ET AL.,
RESPONDENTS.

**Memorandum in Reply to New Boyden Brief on
Third Argument.**

There are two points made in the new brief on behalf of the Boyden Company which are so different from any position heretofore advanced, and, as we trust to show, so erroneous, that we may be pardoned, we think, for requesting permission to file this brief reply.

These two positions are as follows:

First. That no brake is to be classed as a "quick-action" brake which has not the capacity of producing "full application of the last brake on a train of 50 cars within $3\frac{1}{2}$ seconds from the operation of the engineer's controlling cock." This position is advanced on page 5 of the Boyden

brief, and is attempted to be supported by a citation in a note at the foot of that page from the proceedings of the Master Car Builders' Association of 1895 nothing of which appears in the record.

This proposition is repeated all through the argument, and, basing the definition of a "quick-action" brake upon this asserted formula, enunciated in 1895, seven years after the issue of the patent in suit, the brief proceeds to argue that the "quick-action" brake of the patent in suit, No. 360,070, is really not a "quick-action" brake at all, because, upon its first trial, in Burlington, in 1886, it only attained (owing to mechanical imperfections and disproportions) a serial rapidity of six seconds on a 50-car train.

We cannot assent to the correctness of a position which asserts that a standard of efficiency, formulated years after the date of the invention, and based upon its most improved and carefully made forms, is to be taken as a controlling factor in determining the position and value of the mechanism of the patent in suit.

This suit must be determined upon the *record* herein; and the value and position of Mr. Westinghouse's invention must be determined as of the date when it was made.

We have already shown that Westinghouse's invention has features of utility of controlling importance quite different from and independent of any *particular* rate of rapidity in serial action; and this fact will, we think, become still more evident in connection with our answer to the second erroneous position in the Boyden Company's brief.

Second. The second of the two positions in the Boyden Company's brief, which is both novel and erroneous, is this:

On pages 13 to 21 the brief proceeds to point out that between the time when the old automatic brakes used at the Burlington trials of 1886 failed to do satisfactory work, and

the time when Mr. Westinghouse made the invention in suit, which was patented in No. 360,070, March 29, 1887, certain intermediate valves were made, which are described in the testimony of Mr. H. H. Westinghouse, on pages 123 and 124 of the Record, and one of which purports to be illustrated opposite page 16 of the new Boyden Brief. These intermediate valves, it is contended, are to be considered as part of the state of the art prior to the patent in suit, and it is claimed that they tend to limit its scope and impair its position as a pioneer.

In connection with this part of the argument, we desire to call attention to the following facts:

1st. That, on page 16, the brief asserts that "The 'cut' opposite this page illustrates the arrangement described by Mr. Westinghouse."

We can only say that this "cut" is wholly imaginary. No such "cut" is found in the Record, and no structure is described of which the cut can be *fairly* treated as a proper illustration.

The "cut" is *not* the thing which Mr. Westinghouse describes. It adds, among other things, a piston K *to close the discharge port at the proper time*, which Mr. Westinghouse does *not* say was provided, and the presence of which is in conflict with the express statement of Mr. Westinghouse that the use of this experimental discharge resulted in "*a complete exhaustion of the train pipe.*" The significance of this gratuitous addition of piston K will appear later.

2d. The brief asserts on the same page (16) that the arrangement of the intermediate form of valve which operated to discharge air from the train pipe to the atmosphere "does not appear by any evidence in the case to have been the invention of Mr. George Westinghouse, Jr." As to this

last remark, we submit that the record shows exactly the contrary.

Mr. H. H. Westinghouse, in prefacing his description of the supplemental tests which were made, and which led up to the making of the invention of the patent in suit as a result of the failure of the automatic valves at Burlington in 1886, said (p. 122):

"An examination of the results obtained led George Westinghouse, Jr., to make investigations with a view to so changing the form of brake apparatus as to have the effect of operating with a *less interval of time* between the apparatus of the several cars, and also, if possible, provide for a *greater available force*, so as to arrest the motion of the train in a less distance than had been done in the 1886 Burlington trials."

He then proceeds to describe the two preliminary experiments relied upon by the Boyden counsel, viz., 1st (p. 123), the placing in the train pipe at regular intervals of "a form of delicately adjusted exhaust valve," which he says caused a nearly uniform application of all the brakes in "service" applications, but which were of such an "extremely delicate nature" as to render their practical use "extremely doubtful," and which merely "served to demonstrate *the direction of further experiment*;" and, 2d (p. 124), *some apparatus* arranged with an auxiliary valve controlling communication between the brake pipe and the atmosphere and operated by the final travel of a triple-valve piston, which while also quickening serial application resulted in "*a complete exhaustion* of the air from the train pipe at each triple valve."

Mr. H. H. Westinghouse then adds that these suggestive but imperfect experiments finally culminated in the device of the patent in suit, which embraced a *combination*, in one unitary structure, of mechanism for securing *for emergencies*

only, a greatly augmented brake force ("fully 20 per cent.") and a *controlled* quicker serial application of brakes. By *controlled* "quick action" we mean such action as can be caused to operate or remain inoperative at the will of the engineer, and can be applied and re-applied at will, without sacrificing the other necessary functions of a "service" use and graduating use and prompt release after application.

Mr. H. H. Westinghouse concludes his narration of the history of the experiments which led up to and culminated in the invention of the patent in suit by saying of them all (p. 125).

"The experiments and improvements and changes above described were carried on by the suggestion and under the direction of George Westinghouse, Jr."

It is difficult, therefore, for us to understand how the Boyden brief can assert so positively that the record does not show that the alleged intermediate forms were the work of Mr. George Westinghouse, Jr.

But whether they were or were not the work of Mr. George Westinghouse, Jr., is of no real importance, for they resulted, at the time, in nothing practical, and, as mere tentative experiments, they cannot be used to detract from the novelty or merit of Mr. Westinghouse's great invention embodied in the patent in suit. Nor can that invention be minimized by the erroneous assertion that nothing is a "quick-action" brake which does not apply the last brake on a 50-car train in three and one-half seconds.

Mr. Westinghouse's pioneership stands upon a foundation quite different from any mere *rate* of serial quickness of application.

Quickened serial application had been proposed by him in

his patent No. 217,838 seven years before. But *mere* capacity for quickened serial application is not enough. If it had been, it would have been practically utilized long before 1887. The long and heavy freight trains of the modern art, and which modern railway practice had rendered essential, required a brake of *augmented force held under control* for *emergency use* and also one possessing *controlled* quicker serial application.

Greater efficiency of the brake in the rare instances of emergency application, when life and property were in imminent peril, could not, however, be provided for at the sacrifice of the every-day capacity of the brake for "service" use. A brake which is more powerful and quicker in serial application would be a *useless* thing if those qualities were attained only at the sacrifice of the capacity for either delicate graduation or full "service" application at will, or of the power to instantly release the brake after it had been once applied.

A "quick action," which was *always* "quick action," would be an utterly useless brake; a more powerful brake, which must *always* be more powerful, would be an impractical thing.

Hence, neither the suggestion of patent No. 217,838, nor the tentative experiments made by Westinghouse, in his shop, in 1886, in his endeavor to devise *the successful* freight brake of the future, have any relation to the present invention, except to indicate how complicated and difficult the problem was which was solved by it.

A brake of augmented force in emergencies, and in emergencies *only*, and of quickened serial application, but which was not "quick action" *always*, but was under control, was the *desideratum*. A "quick action" which was not destructive of the most important functions of the brake for

ordinary "service" use and which did not depend upon mechanism too delicate to be practical, and which was so organized as not to prevent the brake being released after it had been once applied, was the thing which was required.

All these features are embodied in the invention and apparatus of the patent in suit. None of them are found in the prior patent, No. 217,838, nor practically embodied in the tentative experiments of Westinghouse himself which led up to the patent in suit.

An auxiliary discharge valve of such an "extremely delicate nature," as to make its practical use "extremely doubtful," did not solve the problem, nor did it add anything to the art.

The mere discharge of train-pipe air by a valve controlled by the triple-valve piston, but which, when once opened, resulted in "a complete exhaustion of the air from the train pipe at each triple valve," would be likely to be a valve which could not be released until the brake apparatus of the whole train was manipulated by the few train hands. Hence it added nothing to the art.

The "cut" opposite page 816 of the Boyden brief, and which purports to illustrate the experiment which Mr. H. H. Westinghouse described, *supplements* that description, by illustration of a complicated piston-operated aperture-closing valve (marked "K"), no suggestion of which is made in the record, nor is any description found of how it could be utilized to stop the discharge of air.

By discharging the vented air from the train pipe into the brake cylinder, as the result of the final movement of the piston of a triple valve, Westinghouse solved the complicated problem of "quick action," placed it under immediate control by the engineer, and accompanied it by aug-

mented train-stopping force combined with an *unimpaired* capacity of the apparatus for every function of ordinary use.

Until *all* these things were done, "quick action" was, for practical railroad purposes, unaccomplished.

George Westinghouse, Jr., did them all. He was absolutely the first to accomplish each one of three fundamental features of practical "quick action," viz:

1. Augmented power in emergencies, and in emergencies *only*.
2. *Controlled* quickened serial action, which could be had, or *not* had, at will.
3. "Quick action" with unimpaired capacity for all the necessities of "service" action.

The fact that, in his first apparatus, *one*, and *one only*, of his novel features—that of *controlled* quick serial action—was not *as rapid* as he himself afterwards made it, is a matter of no controlling importance.

BOYDEN POWER BRAKE COMPANY

ET AL.,

Appellees.

Petition for Rehearing.

Your petitioners George Westinghouse, Jr., and the Westinghouse Air Brake Company, complainants and appellees, hereby respectfully represent to this Court as follows:

FIRST. That, as they are advised and believe, this Court has been led into error in its opinion filed May 9th, 1898, in finding that the "auxiliary valve" of Boyden (valve 22) is *located and arranged* in combination with the other parts of the triple-valve structure, in a substantially different manner from that of the auxiliary valve of the Westinghouse Patent in suit (valve 41), and so as to be productive of different results from those produced by the Westinghouse auxiliary

valve; and in finding that a passage for train-pipe air (admitted by said valve) *through* the valve chamber, is substantially different from a by-passage for train-pipe air *around* said valve chamber.

Whereas, as your petitioners believe, this difference in location of the auxiliary valves, and passages opened thereby, is *not* material, and has been so proved in the record, and is in substance so admitted on the part of the defendants in one of the Boyden Patents No. 481,136 (Record, pp. 817, 823).

SECOND. That, as they are advised and believe, this Court has been led into error in its finding that there is "*no partition in the proper sense of the word,*" in the valve structure of the Westinghouse Patent in suit, "*or, at least, none located as in the Boyden device,*" and "*no aperture in such partition open for the express purpose of maintaining differential pressures on opposite sides of a check-valve which opens in emergencies to admit train-pipe air to the brake cylinder.*"

Whereas, as a matter of fact, there has always existed in the said Westinghouse "quick-action" structure, and is described in the Westinghouse Patent in suit a restricted port 35, in an extension of the main valve, which constitutes a partition substantially of the character of that in the Boyden structure, and is located in substantially the same relation to the other parts of the structure, and said restricted aperture necessarily operates to produce "differential pressures" on opposite sides of the Westinghouse check-valve, and is productive of substantially the same results as those produced by the said restricted aperture in the Boyden structure, and this is substantially admitted in the record, and is clearly to be inferred from the said Boyden Patent No. 481,136 (Rec., pp. 823-4).

THIRD. That this Court has been led into error in supposing that the device of the defendants' is substantially different from that of Westinghouse, and "*is a novel one and a manifest departure from the Westinghouse Patent,*" because, as was supposed by the Court, Boyden "*made a more perfect brake than the one described in the Westinghouse Patent.*"

Whereas, there is no proof in the record that the defendants' device is, in any way, or to any degree, better, simpler or

more efficient in producing "quick action" or quickened "serial action" or "quick action without shocks," at the rear end of a long train, than the exact form of apparatus described and illustrated in the patent in suit, but, on the contrary, the proof is that the said Boyden valve is, if anything, inferior to that of the patent in suit.

In support of the first paragraph or section of this petition your petitioners respectfully represent as follows :

The location of the Boyden auxiliary valve 22 upon one side—viz., on the auxiliary reservoir side—of the triple valve piston (and hence *in* the valve chamber), instead of upon the other, or the train pipe side, of the triple valve piston (and hence *outside* of the valve chamber), and the consequent difference of flow of train-pipe air admitted by said valve *through* the valve chamber (as described by Boyden), instead of *around* the valve chamber (as described by Westinghouse) is admitted in the patent of Mr. Boyden himself to be a difference which does not affect either *essential* features of the structure, or the mode of operation or the result.

The Boyden Patent No. 481,136 (August 16, 1892, Record, pp. 817-828) describes a form of quick-action valve operating by the same "momentary differential pressures" (see Rec., p. 821, 5th line from foot of page) as the form involved in this suit, but differs therefrom by using a *slide* valve, instead of a *poppet* valve. Said patent contains several illustrations of *essentially* the same structure.

In one form (Figs. 2 and 11) train pipe air is admitted by a *by-passage* (containing a check valve) *around* the triple valve chamber, and, in another form (Fig. 12) train pipe air is admitted to produce quick action *through* the triple valve chamber.

Also in one form (Fig. 2) the "partition 9," with the "restricted port B" therein, is *movable* (substantially as illustrated in the Westinghouse Patent in suit), and in other forms (Figs. 11 and 12) the "partition" and "restricted port" therein (B¹ in Fig. 11, B² in Fig. 12) is *stationary*.

This Boyden Patent expressly admits that the two organizations of the structure *are substantially alike*. It says (p. 823, 8th line from bottom of page):

"The restricted passage B for the supply of auxiliary reservoir air when applying the brakes for emergency stops is shown in Figs. 2 and 10, for the purpose of clear illustration, as a small hole through the partition 9; but a special hole or passage is not necessary, as the partition 9 may fit the bushing *b* loosely enough to leave a small space between the rim 9^a of the partition and the wall of the bushing. Such looseness of fit, or the space formed thereby, may constitute the restricted passage, and I have used valves constructed in this manner. The restricted passage may also be formed as a distinct channel in the case, as at B¹ in Fig. 11 or as at B² in 12. *The partition may be located differently from what is shown in Figs. 2 and 11. It is obvious that it may be anywhere on the stem q², so that it is not withdrawn from the bushing when the piston completes its stroke to the left. It may also be stated that the piston may, under certain conditions, be made to serve as a partition. This is illustrated in Fig. 12.*

Fig. 12 illustrates a modification in the construction and arrangement of the parts of a valve embodying my invention. This form of valve, *although differently organized from that shown in Figs. 2 to 11, inclusive, has the same parts, or their equivalents, and has the same mode of operation and produces the same result. The valve shown in Fig. 12 differs from that shown in the other figures chiefly in that the slide valve of Fig. 12 is located on the train-pipe side of the actuating piston, whereas in the other figures it is located on the auxiliary-reservoir side of said piston.* (*Italics ours.*)

In further support of your petitioner's contention that the location of the partition, with its restricted aperture, and the location of the "auxiliary" valve, are not substantially different in the Boyden structure from those illustrated in the Westinghouse structure, your petitioner respectfully represents as follows:

In the Boyden structure in suit the "partition 9" is a fixed partition, located between the auxiliary reservoir and the triple valve chamber, and the "restricted aperture" of said partition restricts the free flow of air from the auxiliary reservoir to the brake cylinder for three purposes:

(a) To hold the high pressure at the back of the triple valve piston, so as to cause the piston to move when train pipe pressure on the opposite side is reduced.

(b) To prevent high pressure from existing under the check valve (in the passage from the train pipe), and thus permit said check valve to open.

(c) To supplement train pipe air with reservoir air (*slowly admitted*).

In the Westinghouse structure the part which acts as a "partition," and "restricted aperture" therein, is a *moving* part instead of a *fixed* part. It is the extended end of the main valve with the restricted port 35.

The operation and effect of that partition, and restricted aperture therein, is precisely the same as the corresponding parts of the Boyden structure, viz. :

(a) To hold the high pressure at the back of the triple valve piston, to cause it to move when train pipe pressure on the opposite side is reduced.

(b) To prevent high pressure from existing under the check valve (in the passage from train pipe) and thus permit said check valve to open.

(c) To supplement train pipe air with reservoir air (*slowly admitted*).

The fact that the partition in one case is a moving one, and in the other case a fixed one; and that in one case it restricts the flow of auxiliary reservoir air *into* the valve chamber, and in the other case *out of* the valve chamber (in *both cases on its way to the brake cylinder*), are shown to be immaterial differences by the express admissions already quoted from the patent to Boyden, No. 481,136.

In support of the second section or paragraph of this petition, your petitioners respectfully represent that, while it is true that the Westinghouse Patent in suit does not describe the restriction of size of the "Port 35" as being

"*for the express purpose of maintaining differential pressures on opposite sides of a check valve which opens in emergencies to admit train-pipe air to the brake-cylinder,*"

and although it is true that the Westinghouse Patent does not, in itself, state such "express purpose," yet the evidence shows that the Westinghouse valves made under said patent were always so constructed, and that the structure could not possibly have been operated to produce "quick action" unless so constructed as to contain a restricted passage through a separating partition (which prevents the *free* flow of auxiliary reservoir air at the time quick action is to be effected), and that this was well understood long prior to Boyden's alleged invention of the "partition" and "restricted port B."

Hence, as your petitioners respectfully represent, the use of a partition, and a restricted passage therein, cannot be claimed as a *novelty* by Mr. Boyden or those acting under him.

In support of the third section or paragraph of this petition, your petitioners respectfully represent that there is no proof in the record that the defendants' device is better, simpler or more efficient than that of Westinghouse, or has ever been introduced into public use on railroads to any considerable extent. But, on the contrary, the proof is that the said Boyden apparatus has never gone into extensive practical use, and is not to be distinguished from that of Westinghouse by reason of any greater efficiency, as will fully appear by reference to the citations from the record (and from public documents) in the brief accompanying this petition.

Your petitioners further represent, as a reason for a rehearing of this cause, upon the points specified in this petition, that the aspect in which this case has heretofore been presented upon the question of infringement has been principally, if not wholly, such as not to call the proofs relating to the specific contentions here presented, to the attention of the Court.

The contentions of the respective parties, as heretofore presented, have been chiefly upon the question whether the Boyden "valve 22" was or was not an "auxiliary valve" which performed the function of the auxiliary valve 41 of the Westinghouse Patent in suit in admitting train-pipe air to the brake cylinder in "quick action."

The contention on behalf of the defendants has been that the said Boyden structure contained only and solely a "main valve" and a "graduating valve," but *no* "auxiliary valve" for "quick-action."

The contention on behalf of the complainant has been that the valve 22 of the Boyden structure was essentially a "quick-action" "auxiliary valve," and not the "main valve" of a triple valve structure.

The question has not been, as your petitioners believe, thoroughly, if at all, argued, whether, *if* it should be held (*as this Court has now held*) that the valve 22 is *in fact* an "auxiliary valve" for "quick-action," the mere location of the same inside of the valve-chamber (on the auxiliary-

reservoir side of the triple valve piston) instead of outside the valve-chamber (or on the train-pipe side of the triple-valve piston), and the consequent incident of a passage for train-pipe air *through* the valve-chamber, instead of *around* it, and the further consequent incident of the location of the part which acts as a "partition" and "restricted port," to prevent free flow of auxiliary reservoir air, at the place where it *enters* the valve chamber, instead of at the place where it *leaves* said valve chamber, constitute material differences of structure or are productive of any materially different results.

Wherefore, your petitioners respectfully ask that this cause be reheard upon the specific question, whether the difference in location of the auxiliary valve 22 of the Boyden structure from that of the auxiliary valve 41 of the Westinghouse structure, and the consequent incident of a passage for train-pipe air through the valve chamber, instead of around it, constitutes a material and substantial difference between the two structures, and whether the difference in location and form of the restricted aperture to prevent the free flow of air from the auxiliary reservoir in "quick action," by locating the same in one case at the point where the air enters the valve chamber on its way to the brake cylinder (as in the Boyden structure), instead of locating the same at the point where the air leaves the valve chamber on its way to the brake cylinder (as in the Westinghouse structure), is a material and substantial difference; or whether either of said differences are sufficient to avoid the charge of infringement.

And your petitioners will ever pray, etc.

(Sd.) WESTINGHOUSE AIR BRAKE CO.,
 By GEORGE WESTINGHOUSE,
 President.
 (Sd.) GEORGE WESTINGHOUSE, JR.

We hereby certify that in our opinion the foregoing petition is well founded in point of law and in point of fact, and is not presented for delay.

Brief on Petition for Rehearing.

The decision of the majority of the Court rests largely upon a question which does not seem to have been fully, if at all, discussed.

The validity of the claims of the Westinghouse Patent in suit, so far as the question of novelty is concerned, has never been seriously disputed.

The only question has been in regard to the scope of the invention and of the claims.

On the part of the complainant infringement has been presented in two aspects :

FIRST. On the ground that the complainants were entitled to claim broadly, under their second claim, any quick-action triple-

valve apparatus in which the triple-valve piston, by a short or "preliminary" traverse, opened a port from the auxiliary reservoir to the brake cylinder, and which, by a longer or "further" stroke, opened a port from the train pipe to the brake cylinder.

If this position could be maintained, it became unnecessary, under the second claim, to discuss the question whether the valve which opened the train-pipe port was an "auxiliary" valve or not.

The majority of the Court has ruled against this construction of the second claim, and has held that an "auxiliary valve" is an implied element of the second claim.

SECOND: The second contention of the complainants was that the defendants' valve 22 was, in fact, an "auxiliary valve," and that, having all the other elements recited in the combinations of the 1st, 2d and 4th claims, this structure was an infringement of each of those claims.

The contention throughout the case on behalf of the defendants has been a denial that their valve 22 was, in fact, an "auxiliary" valve at all. Their contention has been that the valve 22 was the "main valve" of the triple valve, and that the valve *i, j, k* was a mere graduating valve.

This Court has ruled against the defendants on this contention; but, in the opinion of the majority of the Court, as we read the opinion, the difference in *location* of the defendants' auxiliary valve 22 is believed to be so different from that of auxiliary valve 41 of the Westinghouse Patent, and its arrangement in connection with an air passage *through* the valve chamber, instead of in connection with an air passage *around* the valve chamber, productive of such different results, and involving such a different mode of operation, that infringement has not been made out.

In connection with this issue the Court has held that, although in the Westinghouse Patent the *restricted port 35* is present, and necessarily produces that difference of pressure on opposite sides of the check valve which is essential to the opening of the check valve to admit train-pipe air for "quick action," yet this particular func-

tion of the restricted aperture, being not in terms adverted to by Mr. Westinghouse, is to be regarded as an incident to the form of the structure rather than as expressly in the mind of the designer. Hence it has not been recognized as the equivalent of the Boyden port B, in his partition.

If we are able to show that the *location* of the auxiliary valve inside of the triple-valve chamber, instead of outside of it, is an immaterial difference, then, as we respectfully submit, the two other differences above referred to must necessarily be held to be immaterial also, because they will then be seen to be mere incidents to the change of location of the auxiliary valve.

Thus, if the auxiliary valve be really an "auxiliary" valve, acting as such, but located in the valve chamber, instead of outside of it, then it follows of necessity, and as a mere incident, that the flow of air which it admits, when opened, *must be through* the valve chamber instead of *around or by* it.

One feature follows of necessity from the other.

Again, it also follows of necessity, from the location of the auxiliary valve *in* the valve chamber, that the point of *restriction* of free flow of air from the auxiliary reservoir must be situated to accord with such changed location of the auxiliary valve.

Train-pipe air at reduced pressure is to be allowed to flow past the auxiliary valve when opened. That is the sole purpose of such valve. When the auxiliary valve is open the reduced train-pipe pressure must also be sufficient to open a check valve in the line of flow thus opened. Hence, auxiliary-reservoir air *at higher pressure* must not be allowed to be present in the line of flow opened by the auxiliary valve; the flow of such air *at high pressure* must accordingly be restricted.

If the auxiliary valve is located *in* the triple-valve chamber, of course the free flow of high pressure auxiliary-reservoir air must be restricted *before* that air *enters* the valve chamber, on its way to brake cylinder.

If the auxiliary valve is located *outside* of the valve chamber,

then the free flow of high pressure air need not be restricted until it is *leaves* the valve chamber, on its way to brake cylinder.

Hence, the *place* of restriction of free flow of reservoir air (or location of the restricted port) is merely an incident to the location of the auxiliary valve.

In the Westinghouse structure the restriction is at the point where the reservoir air *leaves* the valve chamber, because the *auxiliary* "quick-action" valve is *outside* of that chamber, and the line of flow of train-pipe air is *around* the chamber—to brake cylinder.

In the Boyden valve, simply because the auxiliary valve is *in* the triple-valve chamber, the restriction of flow of high pressure air must take place *before* it enters the valve chamber, in the line of flow through that chamber to brake cylinder.

There is no other difference between the two structures, and, as we shall now proceed to show, change of location of the valve and of the restricted passage for the flow of train-pipe air is a mere change of location, not production of any new mode of operation, nor of any better or different result.

First Point. On the record, as it stands, defendants can not successfully argue that *in re quick action*, either the *location* of their partition 9, or the presence of a *central passage*, was a material or substantial difference.

As a part of their defense they offered in evidence three Boyden Patents, all of the same date (August 16th, 1892), and consecutively numbered. All of these three patents were asserted to be addressed to a common object, viz.: the production of "quick action" by the admission of train-pipe air, by a valve which, in each case, is *said* to be only the "main valve," whereby, as is said, "an auxiliary valve is dispensed with and 'quick action' by the admission of *train-pipe* air effected by 'momentary differential pressure'" (Rec., p. 821, foot of page).

The first patent of the three, No. 481,134 (Rec., p. 797), related to the first form of defendant's infringing apparatus, about which very little was said at the argument or in the briefs, since it had been superseded by the second form, and the differences between the two were not regarded as very material.

The second patent of the three, No. 481,135 (Rec., p. 809), related to defendants' second form of valve. This is the one which was chiefly discussed at the hearing and is illustrated with substantial correctness in the drawings, and skeleton diagrams next following pages 15 and 16 of the opinion.

The Court has held that the valve 22 of the patent is *really* an "auxiliary" valve.

The third patent, No. 481,136 (Rec., p. 817) relates to another form or construction of quick-action triple valves in which the *alleged* "main" valve is a *slide* valve instead of a poppet valve. Whether it, like valve 22 of Patent 481,135, is not really an "auxiliary valve" need not now be discussed, as such valve is not in issue in this case, but (as will be seen at p. 821, line 5, from bottom of page) it so far resembles the other two as to involve a like exploitation of Boyden's theory of "momentary differential pressures," and (pp. 827-8) of the value of a "partition," and of "a restricted port" therein.

Now a reference to this patent will show that the *location* of the partition 9, with its restricted port B "between the chambers C and D," is *clearly not a matter of importance at all* in respect to producing "*quick-action*" by admitting *train-pipe* air.

In the specification (Rec., p. 819), a little below the middle of the page, Boyden says:

"A restricted or small passage B through the partition 9 serves as an air communication between opposite sides thereof."

Referring now to Fig. 2 of these Boyden drawings (Sheet 2), it will be seen that the partition 9, with its restricted passage B, is *not* "between the chambers D and C," but is located in an extension of the piston stem at the right-hand end of the valve cham-

ber C, and connects with a *by*-passage to brake cylinder (*as in the Westinghouse Patent in suit*). In Fig. 12 (Sheet 5) the partition 9 is a *movable partition*, being the main piston itself (Rec., p. 824, lines 7 and 8), and the restricted port or passage B² is there located in the valve casing.

Mr. Boyden and his company, who introduced this patent, are not in position to argue that *in re quick action* the particular *location* of the partition 9 with its restricted port B, between the chambers D and C, involves any matter of substance, because in one figure (2) they show it located as in the Westinghouse valve, and in another figure located substantially as in the particular Boyden valve in suit (*i. e.*, between chambers C and D).

This patent of Boyden's, No. 481,136, therefore, supports our contention that the *location* of the partition and restricted port is not material in respect of quick-action, and that they may be located at any suitable point, either *between the valve chamber and passage to brake cylinder*, where Westinghouse shows them, or *at the end of the valve chamber next the piston*, as in the particular structure before the Court, or *at the end of the valve chamber furthest away from the piston chamber*, as in the Boyden Patent No. 481,136.

But Boyden, in this patent, goes still further, and specifically admits, what we have always contended for, that the *location of the partition is not material*. Thus (Rec., p. 824, lines 3-5), he says :

"The partition may be located differently from what is shown in Figs. 2 and 11. It is obvious that it may be anywhere on the stem g²," etc.

And again (Rec., p. 824) :

"Fig. 12 illustrates a modification in the construction and arrangement of the parts of a valve embodying my invention. This form of valve, *although differently organized* from that shown in Figs. 2 to 11, inclusive, *has the same parts or their equivalents and has the same mode of operation and produces the same result*. The valve shown in Fig. 12 differs from that shown in the other figures chiefly in that the slide valve of Fig. 12 is located *on the train-pipe side of the actuating piston*, whereas in the other figures it is located *on the auxiliary reservoir side of said piston*" (*italics ours*).

Hence, while we submit that the Court is in error in believing that *the particular location* of the partition 9 is a matter of substance, we can readily see that the error probably arose, as above stated, from a misapprehension of defendants' contention, and a misapprehension which was very liable to arise on account of the exceedingly complicated character of the mechanics of the case.

It will also be seen that in this same Boyden Patent No. 481,136, Boyden has shown that a *central passage*, through the triple-valve piston) and through the valve chamber, is not essential to his theory of "momentary differential pressures," for here will be found in Figs. 2, 5 and 11, a *by*-passage F¹, and a check-valve 26, controlling the flow of train-pipe air through such *by*-passage. And from this fact the inference is fairly obvious that *in re quick-action* there is no substantial or material difference between a "by-passage around the triple-valve chamber and a *through passage*."

Second Point. In respect to the Westinghouse Patent in suit, 360,070, the Court finds :

"The fact, however, that no suggestion is made in the patent of such a function of the restricted port 35, indicates either that none such had been discovered, or that it was not considered of sufficient importance to mention it. Indeed, it seems to have been an after-thought, suggested by the necessity of an answer to defendant's argument, based upon their partition 9. That when an auxiliary valve is opened there must be a difference in pressure above and below the check valve 49, in order to open it, is manifest ; yet, this is rather an incident to the Westinghouse device than the controlling feature that it is made in the Boyden patent " (Opinion, pp. 21, 22.

As to this your petitioners respectfully submit :

1. Differential pressures as a means of brake control had been a known and recognized branch of this art in the automatic system, and such fact abundantly appears from the testimony in the case.

Barnes, Rec., p. 373, fol. 578.

2. The main valve H of the Westinghouse automatic Patent 220,556 (Rec., p. 762) contained a service port s¹ for admitting *aux-*

iliary-reservoir air to the brake cylinder in the ordinary service applications of the brake, such port then being brought to register with the brake-cylinder port C. But when the brake was to be applied with *full force* the further traverse of the piston brought the extreme end of the valve H clear past the brake-cylinder port C, so that the latter was *wide open* for the *abundant* discharge of auxiliary-reservoir air into the brake cylinder.

And this is the feature on account of which the "further traverse" of this valve, as thus constructed, was rendered unsuitable for use for *quick-action* purposes (as was admitted in Mr. Hill's second brief, p. 12).

If this construction had been followed in Patent No. 360,070, *auxiliary reservoir* air would enter the brake cylinder *as freely and as fast as train-pipe* air could pass through the emergency port 42 of 360,070, and the latter, being of *less* pressure, "*quick-action*" would be impossible.

Hence, Mr. Westinghouse, in devising the apparatus of 360,070, made an extension of the extreme end of the main valve (called H in 220,556), and in that extension he made a small or restricted port 35; and this fact is specifically referred to by him in his specification (p. 3, lines 4-19), where he first enumerates the leading operative parts of the triple valve of 220,556, and then says (lines 9-12):

"But *under my present invention these are supplemented by a port 35, leading from the end of the valve adjacent to the opening of the chamber 24.*"

The port 35 is, therefore, a new feature introduced for some purpose in devising the quick "action" invention.

Next, what does the Patent 360,070 say about the relative sizes of the ports 35 and 42?

Of the port or passage 42, it says (p. 4, lines 34-42):

"Not only is there a passage of *considerable size* opened from the brake pipe on each car, whereby the pressure is more quickly reduced, but the air so discharged is utilized in the performance of preliminary work, it being found in practice that the air so taken from the pipe will exert a pressure of about twenty-five pounds in the brake cylinder" (*italics ours*).

Next, we have the following directions as respects the port 35 (p. 4, lines 43-67):

"When the piston 12 arrives at the extremity of its stroke, as above specified, *the supplemental port 35 of the slide valve 14 is brought into communication with the port 33 and passages 22 and 16, which serves to discharge the reservoir pressure into the brake cylinder, thereby augmenting the pressure already exerted in the brake cylinder by the air admitted from the main air pipe.* * * * The feed-opening for the admission of air from the *auxiliary reservoir* to the brake cylinder *is purposely made of comparatively small diameter*, it having been determined by experiment that the initial application of the brakes should not be made with maximum force, and this opening may be made of such size as to apply the brakes exactly in accord with the requirements of the most efficient work." (*Italics ours*).

Hence it is submitted that the Patent 360,070 clearly sets forth in substance the following facts:

(1) That the port 35, with the extension in which it is made, was added to the automatic main valve of 220,556, with reference to and for the express purposes of quick action.

(2) That the port 35 (for reservoir air) is "purposely made of comparatively small diameter."

(3) That the port 42 (for train-pipe air) is to be made of "considerable size."

And these ports being so made, it fully appears from the testimony that "differential pressures" *will certainly be attained*, and that *such fact was well known in the art* (*Barnes, Rec.*, p. 362, fol. 560 (*b*); p. 367, Q. 670; p. 373, p. 371, par. 1; p. 386, fol. 599; p. 406, Q. 701; p. 445, x-Q. 827; p. 453, x-Q. 852. *Newbury, Rec.*, p. 157, Qs. 199, 200; p. 160, Q. 202; p. 163, Q. 205; p. 212, x-Qs. 248-252. *Westinghouse, Rec.*, p. 276, fol. 424; pp. 285, 286, fol. 439; p. 287, Q. 417; p. 289, Q. 422).

Hence, it is submitted that the construction and operation referred to had been "discovered" by Westinghouse; that in respect thereof, sufficient "mention" was made to enable others skilled in the art to make and use it; that it should not be regarded as an "afterthought" nor a mere "incident to the Westinghouse device," and that as to these matters the Court was inadvertently in error.

Defendants did not deny the actual existence of this relation of the ports in the Westinghouse quick-action triple of 360,070. Nor did they deny that the flow of air from train pipe and auxiliary reservoir into the brake cylinder would, as a matter of fact, take place accordingly. Their leading expert, Mr. Church, says unhesitatingly in his direct examination, that the Westinghouse valve of 360,070 contains provisions for a *larger flow of train-pipe air* to the brake cylinder, in emergency use, than from the *auxiliary reservoir* to the brake cylinder.

This is merely the converse of the proposition that Westinghouse restricts the flow of auxiliary air.

Thus, Church says of 360,070 (Rec., p. 605, fol. 980) :

"The passages and ports through which *train-pipe* air is conducted, are *relatively larger* than those through which *auxiliary* air is conducted to the brake cylinder ; consequently, the flow of *train pipe* to the brake cylinder *would precede auxiliary reservoir air, and a relatively larger volume would pass in a given time*" (Italics ours).

Mr. Church tries to belittle the effect of this rapid admission of train-pipe air, but the *fact* is clearly admitted.

(See, also, the further testimony of the same witness in Re-d. Q. 239, Rec., pp. 656, 657, fols. 1059, 1060.)

It is undoubtedly true, however, that in the specification of 360,070—and this is perhaps what the Court had more prominently in mind—the particular operative or co-operative relationship between the restricted port 35 and the check valve 49, whereby, in consequence of the holding back of auxiliary reservoir pressure at the port 35 (except in small amount), train-pipe air at a *less* pressure will lift the check valve 49 and pass freely to the brake cylinder, is not specifically stated as a matter of importance.

But the *fact* remains—and by the facts, as we respectfully submit, we should be judged—that the relationship thus referred to *does actually exist* in the Westinghouse apparatus as shown and described, and also exists as a mechanically co-operative relationship, for the useful purposes for which the apparatus was designed. And it is still further a fact, as clearly appears from the citations made from the patent as above, that the devices thus referred to came

into this co-operative relationship, not *by accident*, but *were made so by design*, to the end that the hitherto unattained purposes and functions of quick action, in a *new kind* of train control, might be accomplished.

Indeed, as we understand, the Court has found the fact to be as we have thus represented. For it is admitted in the above extract from the opinion of the Court:

"That, when the auxiliary valve is opened, there *must be* a difference of pressure above and below the check valve 49 in order to open it, is manifest" (italics ours).

This being true, does it not necessarily follow that suitable means for securing "differential pressures" *actually existed* in Westinghouse's apparatus?

And, if it existed, it must, to the extent and for the purposes of its existence, be a "controlling feature" in the use of the Westinghouse valve, and as much so as in the Boyden.

Hence, if it actually existed, as the Court has found, in operative form in Westinghouse, any failure on the part of Westinghouse to fully appreciate or even to state its importance *cannot*, as we submit, *by any rule of law, inure to the credit of Boyden*.

Boyden is not entitled to high rank as an independent inventor, merely because he has *set forth* in his patent something as a "controlling feature," which, in substance and effect, was already present, and was, in fact, a "controlling feature" in Westinghouse's previously-existing valves, no matter who invented them, nor how defectively or imperfectly their functions were *described*, provided only their construction and operation were previously known.

Third Point. Your petitioners also submit that error of inadvertence also appears in the following finding of the Court:

"There is no partition [in Westinghouse] in the proper sense of the word—certainly none located, as in the Boyden device, between the chambers D and C, and no aperture in such partition opened for the express purpose of maintaining this differential pressure" (Opinion, p. 22).

If "partition" means something which mechanically affects

separation—and the mechanical test is the usual standard of judgment in patent cases—then it is believed that the finding that Westinghouse has no partition “in the proper sense of the word” is erroneous.

The extension on the end of the main valve, above referred to, with its restricted port 35, (which the Westinghouse Patent in suit expressly says is a “supplement” to the older construction of Patent No. 220,556), is *mechanically* as much a “partition” to effect separation between the auxiliary reservoir and the brake cylinder as is the Boyden partition 9, with its restricted port B; Nor in this regard does it make any substantial difference *in respect of separation that at the time when separation becomes important* the Westinghouse partition is *movable* and the Boyden partition is *fixed*.

Both devices equally and in substantially the same way—that is, by blocking, restricting or impeding the flow from auxiliary reservoir to brake cylinder, except through the restricted port 35 of the one or B of the other—secure the same results, and in the same way. We have shown, also, that the fact that a “partition” with a restricted port therein is *movable* rather than *fixed* is admitted by Mr. Boyden himself, in Patent No. 481,136, *to be an unsubstantial difference*, because he illustrates the invention of that patent in one form (Figs. 11 and 12) with a movable partition (9) substantially like Westinghouse’s.

Fourth Point. Your petitioners, therefore, respectfully submit that the Court inadvertently erred in supposing, as it did, that *the location* of the Boyden partition 9 “*between the chambers D and C*” is a material difference, or a difference of substance—that is, as respects “*quick-action*.” No such contention was made in the oral arguments of defendant’s counsel.

Defendants’ position was this: That their valve 22 was *not* an “*auxiliary*” valve, but was *the main* valve; and, in support of *this* contention, they emphasized the location of their partition 9—that it was *so* located that it provided for the admission of *auxiliary*

reservoir air along with *train-pipe* air to the brake cylinder, and that as the admission of *auxiliary reservoir* air was in the old automatic brake a function of the *main valve*, therefore, this particular location of the partition 9 tended to make their valve 22 the "*main*" valve, and not an "*auxiliary*" valve. This, as we recall the argument, was the substance of their contention.

But the Court has found, in substance, as we read the opinion, that defendant's valve 22 is, in fact, an "*auxiliary*" valve, and a "quick-action" valve, notwithstanding the fact that, when it is opened in emergency use for the admission of *train-pipe* air, some auxiliary reservoir air—i. e., as much as can pass through the restricted port B—also passes through with it.

Hence, the Court having found, against the contention of defendants, that the location of the partition 9 does not have the effect of converting the valve 22 into a "*main*" valve, but leaves it still an "*auxiliary*" valve, it would seem to follow that the mere location of the partition 9 ceases to be a material fact in the case, especially in respect of quick action. Putting the partition 9 with its restricted port B between the chambers D and C, or putting it at any other point in the line of flow from auxiliary reservoir to brake cylinder, while to a limited, but insignificant, extent it may affect valve 22, does not in any manner, nor to any extent, affect the essential features of the structure, as they are combined to produce "quick action."

A similar argument holds also in reference to the "central passage" which defendants have provided through their triple-valve piston, as compared with the Westinghouse by-passage. Defendants relied on their central passage in support of their contention that their valve 22 was a "*main*" valve, and not an "*auxiliary*" valve.

The Court has found this fact against them.

Hence, it would seem to follow that, in *re quick action*, the difference between a *central* passage and a *by-passage* is not a difference of substance.

Careful attention to the purpose and mode of operation of the

separating partition and its small port will, we submit, show that the *location* of such "restricted port" is not substantial, provided only it be located somewhere in the line of flow of air from the auxiliary reservoir to brake cylinder, and at *any* point in such line of flow, where it accomplishes the following objects, viz. :

(a) Restricts the flow, so that the reservoir air will be at *high* pressure behind the triple-valve piston, to move it when train-pipe pressure is reduced ;

(b) Restricts the flows, so that such auxiliary reservoir air will *not* be at high pressure behind or under the check valve in the passage from train pipe.

(c) Admits reservoir air *slowly* as a supplement to train-pipe air.

These are the only purposes of the "restricted port," and they can all be as well accomplished in Westinghouse's location as in Boyden's, and *vice versa*.

Fifth Point. We submit, also, that the Court inadvertently erred in finding that Mr. Boyden,

"has made a more perfect brake than the one described in the Westinghouse Patent" (Opinion, p. 22).

This error was doubtless made through reliance on the statements of counsel at the argument ; for with a good knowledge of the contents of the record, and after a careful re-examination thereof, we are unable to recall or to find any testimony which can support such a finding. And so far as the proofs go, they are to the opposite effect.

Mr. Boyden is the only witness for the defense whose testimony even approaches the subject (Rec., pp. 515, 516, fol. 844) ; and he does not allege, nor even intimate, that his brake is any *better* than the Westinghouse. It is as certain as anything can be, that he would have said so, if he could. His silence certainly fails to support the finding of the Court.

Elsewhere in defendants' proofs, this matter is never referred to at all.

Nowhere does it appear that any considerable number of the Boyden brakes were ever actually sold, and still less does it appear that they were ever used, either successfully or otherwise.

Two of complainants' witnesses, Kidder and Nellis (Rec., pp. 425, 433), got together three cars (fol. 678) equipped with the Boyden brake, and tried them experimentally to see whether the Boyden valve 22, in actual use, had the operation of a *main* valve, or an *auxiliary* valve. They found it to be the latter.

Aside from this, the record contained no proof whatever as to the actual operativeness of the Boyden brake.

True, it worked on a short three-car train, but this proves nothing as to its efficiency *in emergencies on a long fifty-car train*. The old "automatic" without "quick-action," met all the requirements of use on short trains. It was only when *long* trains are to be handled that "quick-action" becomes an element of commanding importance.

The record is entirely silent as to the efficiency of the Boyden brake on a *long train in an emergency*. There is no proof whatever that it was ever so used or even tried. For aught that appears, if it had been subjected to the rigid tests and high requirements of the Burlington trials, its operation would have been found to be quite as defective for the practical requirements of quick action as that of the Westinghouse.

But as against any inferences favorable to the Boyden brake which may be drawn from the record we show by our testimony that the Boyden device is seriously defective in the proportioning of its ports and passages, and this testimony is not replied to.

Westinghouse, Rec., pages 296, 297, Q. 447.

If it is ever admissible to supply a paucity of record proof by reference to official reports of a governmental department, the present would seem to be such a case.

The Government of the United States publishes each year in its official reports of the Interstate Commerce Commission the number of railway cars then furnished with power brakes, as

reported to them by the railway companies, and the designating name of each.

We suppose that this Court may (at least in a matter not specifically contested on proofs) take notice of such "Public Documents" (*New York Indians vs. United States*, decided at this Term, April 11, 1898).

We collate from these reports the following tabular statement (with references to pages):

Report.	Boyden.	Westinghouse.
1890, page 36.....	86	144,085
1891, " 46.....	184	178,492
1892, " 28.....	282	245,276
1893, " 26.....	796	287,703
1894, " 26.....	1,690	315,729
1895, " 28.....	1,491	345,836
1896, " 28.....	439	428,805

The report for 1897 is not yet published.

These figures would seem to indicate that the Boyden brake has not recommended itself in practice, in view of the showing that the number of cars equipped with it has decreased from the maximum of 1,690 in 1894 to 439 in 1896—a falling off of over 70 per cent. in two years.

But, if the Court based its conclusion on the defective action of the apparatus of 360,070, when first tried at Burlington in 1887, then we may suggest in reply:

1. That such defective action arose largely from an improper proportioning of ports and passages, not of the valve itself, but of the "accessory parts" used in connection therewith, which defects, however, were corrected long before Boyden took up the subject at all, and thereafter this brake of 360,070 worked well.

Westinghouse, Rec., pp. 151, 152, fol. 228.

Westinghouse, Rec., p. 155, Qs. 190, 191.

2. Newly-invented apparatus, especially of a complicated character, rarely works perfectly on its first trial.

3. If the number of valves in use be adopted as a test of comparative merit between the Westinghouse and Boyden, then the Westinghouse valve of 360,070 is the "more perfect" valve.

Between *two and three thousand* of these very valves were sold to three leading Western roads and were still in use when the testimony was taken.

Westinghouse, Rec., pp. 305, 306, x-Q. 485, 486.

Also, about three or four hundred of these same valves of 360,070 were sold to the Baltimore and Ohio R. R. Co., and were used in passenger-train service for about two years, when the Westinghouse Company replaced them with their standard form of valve, No. 376,837.

Westinghouse, Rec., 304, 305, x-Q. 477-479.

Sixth Point. We respectfully submit, therefore, that an opportunity should be given for a rehearing upon the particular question whether the changed location of defendant's "auxiliary valve" and "partition" and "restricted port" is sufficient to avoid the charge of infringement.

<i>et al.</i>	}

Sur Petition of the Westinghouse Air Brake Company, *et al*, for Writ of Certiorari to United States Court of Appeals for Fourth Circuit.

This is a petition for a Writ of Certiorari to bring Nos. 131 and 134, decided in the United States Court of Appeals for the Fourth Judicial Circuit, before the Supreme Court for its review and determination.

BRIEF IN OPPOSITION TO THE PETITION.

In this petition are twelve assignments of variance and error. An analysis of these assignments shows that they may be grouped into three classes.

1. Variances between the decision of the Court of Appeals for the Fourth Circuit and the decision of the Court of Appeals for the Second Circuit on the same subject matter. These are stated in assignment 1.

2. Variance between a ruling by the Court of Appeals for the Fourth Circuit and the decisions of the Supreme Court on the effect of the phrase "substantially as set forth." And variance with the Circuit Court of Appeals of the First Circuit on the effect of erasure from the original specifica-

tion. These variances are alleged in the fourth and fifth assignments. They really could be grouped with simple assignments of error, as the assignments *are more properly assignments of error* than assignments of variance.

3. Assignments of error. These are described in the third assignment, wherein error is alleged in the ruling of the Circuit Court of Appeals for the Fourth Circuit on the *weight of evidence* as connected with the practice of the Patent Office, and in the second, sixth, seventh, eighth, ninth, tenth, eleventh and twelfth assignments, wherein error is alleged in the rulings of the Court on matters of law and fact concerning the construction and validity of the patent in suit, and its infringement.

We have grouped the assignments into these three classes, because it seems manifest from the uniform decisions of this Court, as hereinafter pointed out, that the second and third classes just mentioned, furnish no ground for the application of the Writ of Certiorari, **AND THAT THE ONLY QUESTIONS TO BE REALLY CONSIDERED UPON THIS APPLICATION ARE THOSE ARISING UNDER THE FIRST CLASS OF ASSIGNMENTS, e. g.,** wherein variances are claimed to exist, as to subject-matter of the litigation, between the rulings of two appellate Courts whose decisions in patent cases are ordinarily final.

The brief for the petition discusses only the first five assignments.

GROUNDS FOR CERTIORARI UNDER THE ACT OF 1891.

This Court has described at length the class of cases which it will review by Writ of Certiorari, in several cases, to wit:

American Construction Co. vs. Jacksonville Railway Co., 148 U. S., 382.

Lau. Ow. Bew's Case, 141 U. S., 583 ; 144 U. S., 55.

In re Woods, 143 U. S., 202.

Columbus Watch Co. vs. Robbins, 148 U. S., 270.

From an examination of these cases the following principles may be deduced as governing all applications for certiorari of this character.

1. The object of the act was to relieve the Supreme Court of the overburden of cases, and to accomplish this to transfer a large part of its appellate jurisdiction to the Circuit Courts of Appeals.

2. The act is to be uniformly construed so as to promote this purpose, and especially in those classes of cases wherein, as in patent cases, the judgment of the Circuit Court of Appeals is, by this act, *made final*.

3. The power to bring up cases by certiorari is a branch of the jurisdiction of the Supreme Court "which should be exercised sparingly and with great caution, and only in cases of peculiar gravity and general importance, or in order to secure uniformity of decision."

Am. Construction Co. vs. Jacksonville Ry. Co.,
148 U. S. 382.

From this analysis it is apparent that a certiorari writ will not be granted unless the cause "is of peculiar gravity and general importance," or unless there is a substantial variance of decision on the *same* subject matter and under the same conditions. We will discuss this case under these headings.

(A.)—CASES OF PECULIAR GRAVITY AND GENERAL IMPORTANCE.

Independently of the questions of variance which we will discuss hereafter, there are no questions in this case different in any respect from those which usually arise in patent cases. There is no unusual, extraordinary or fundamental question, even on patent law, involved in any of the assignments of error. None of these can, by any possibility, be brought within the meaning and scope of the phrase, "cases of peculiar gravity and general importance."

What did this Court mean when they declared that in "cases of peculiar gravity and general importance" they would review a case by certiorari, even though otherwise made final by the Act of 1891?

Evidently the gravity and importance of the case is to be found in the *nature* of the question, and not in the mere

sum of money involved, or in the extensive use of the invention. If it had been the intention of the Act to give a hearing in the Supreme Court to such patent causes as involved large sums of money, such intention would have been expressed and the amount fixed. But by the Act all patent causes are finally decided in the Circuit Courts of Appeal. Nor can a patent which is used in every State in the Union have any right to a hearing in the Supreme Court which is denied to a patent with less extensive use. No such discrimination would be practicable. A patent of limited use to-day might be in universal use next year.

An examination of all the cases shows that in the entire history of this Court since the Act of 1891 was passed, *not a single application for a certiorari in a patent case has been granted*, when the only questions involved were such as usually arise in patent cases, and such as arise in this case.

In the following cases the writ was denied:

Sawyer Man Co. vs. Edison Electric Co., 11 U. S. A., 712; 149 U. S., 785.

This case involved the Edison incandescent electric lamp, which is in extensive use.

Stewart vs. Smith, 17 U. S. A., 217; 154 U. S., 519.
Case of design patent.

Singer Sewing Machine Co., vs. Brill, 7 U. S. A., 601.
Sewing machine patent.

The David Bradley Mfg. Co. vs. The Eagle Mfg. Co., 18 U. S. A., 349; 154 U. S., 500.

Improvement in cultivators.

These were cases of valuable patents, several of them of *very extensive use through all judicial circuits*, involving the investment of large sums of money. But the application was denied in each case because no questions of "peculiar gravity or general importance" were involved.

It appears that in two patent cases only, since the Act of 1891, has this Court granted the writ of certiorari, and in these the special reasons for the Court's action are apparent.

In the case of Grosvenor vs. Dashiell, the patent involved was No. 425,584, granted to Samuel Seabury for improvement in breech-loading cannon. The bill stated an ordinary case involving questions of the validity and infringement of a patent, but alleged also that Dashiell, who was an officer of the United States Navy, was connected with the Bureau of Ordnance of the Navy Department, and that he conspired with Commodore Folger, who was in charge of the department, to use the complainant's invention and deprive the patentee and his assignees of the benefits and royalties secured by the patent.

This case in the Circuit Court of Appeals for the Fourth Circuit did not turn on any question of patent law, but upon the very grave and important question as to the right of the government in its sovereign capacity to use a patented device in the manufacture of implements of warfare indispensable to the armament of its vessels of war, without being liable to be stopped by the patentee by injunction. As Circuit Court Judge Goff decided :

"We do not think that contending patentees, striving between themselves and those interested with them, as to the validity of their respective letters patent, should be permitted to close the arsenals, ordnance shops and navy-yards of the United States by injunctions issuing out of their litigation, thereby frustrating the designs of the government, rendering inoperative the legislation of Congress germane thereto, and causing great loss of the public funds appropriated by Congress in execution of the same."

Hence, it will be perceived that though this question arose in a patent case, it was not a question of patent law at all, but was an important governmental question, in which the United States was vitally interested.

The only other case in which a patent was involved, and in which a certiorari was granted, is the case of Vulcan Iron Works vs. Samuel R. Smith et al.

In this case the question involved was the *jurisdiction* of the Circuit Court of Appeals. On the question of juris-

diction, the decisions of the Circuit Court of Appeals of various circuits were at variance; and this variance was vital to the rights of the petitioners, for it appeared that if the case had been decided in one circuit the decree would have been affirmed; but as it was decided in the other, the decree was reversed.

This case presented two vital and important questions: First, the jurisdiction of the Circuit Court of Appeals; and second, an absolute variance between the circuits on this jurisdictional question; and upon the decision of these questions the rights of the petitioners in the case depended. Neither of these questions are mere questions involving patent law.

What extraordinary or unusual question "of peculiar gravity and general importance" is presented by the record in the *present* case? There is no governmental question; no question of jurisdiction; no issue in which any one is especially interested except the parties litigant. If the writ of certiorari should be granted in this case, on the ground we are now discussing—peculiar gravity—it would be an innovation upon the established practice of this Court, and no good reason can be perceived why like writs should not issue in any subsequent cause at the instance of any litigant who felt that his patent had not been properly construed by the Circuit Court of Appeals.

If the shoe were on the other foot, and we had secured an injunction against the Westinghouse Company, and this injunction had the practical result of obstructing interstate traffic, or the carrying of the mails with safety, then, indeed, an unusual question would arise which might call the discretionary power of this Court into action.

But the only practical question in dispute in this case was whether the Westinghouse Company should have the sole monopoly in supplying the railroad companies with "quick-action automatic air-brakes," or whether the Boyden Company should have the right to supply their own special contrivance in competition. This is, therefore, a mere *private litigation* embracing no question of "peculiar

gravity or general importance ;" and on this ground, unless there is something in the question of variance, the application for the writ of certiorari should be denied.

(B).—VARIANCE.

The petitioners, however, rest their case mainly on the ground of an alleged variance between the decisions of the Circuit Court of Appeals for the Fourth Circuit and the Circuit Court of Appeals for the Second Circuit on the same subject matter—to wit, Claim 2 of Patent 360,070.

In their petition they cite four decisions in the Circuit Court and the Circuit Court of Appeals of the Second Circuit, as follows :

Circuit Court, Judge Townsend, 59 Fed. Rep., 581.

Circuit Court of Appeals, Judge Shipman, 63 Fed. Rep., 962.

Circuit Court, Judge Lacombe, 65 Fed. Rep., 99.

Circuit Court of Appeals, per curiam, 69 Fed. Rep., 615.

Petition, pp. 3-4, par. 8-12.

The patent here in controversy, 360,070, was not in issue in the first two decisions.

The variance alleged in the petition and relied upon in the brief of complainants, is between the decision of Judge Lacombe, as affirmed, per curiam, in the Second Circuit and a decision of the Circuit Court of Appeals for the Fourth Circuit.

In their brief the petitioners argue that a certiorari should be granted under the Act of 1891 :

(1). In cases of variance between decisions of the Circuit Court of Appeal of different circuits in adjudications upon the same patent.

(2). When the patent involves rights of sufficient importance to justify the intervention of the Supreme Court.

The importance of the invention embraced in patent 360,070 is described in their brief, pages 2-7; here it is made to appear that the patent in suit is one of great

importance and "value in promoting the public interest," and in answer to the averment in the petition on page 6, to the effect that the *device of the patent in suit is in use on 400,000 freight cars*; it should be stated that the testimony shows the device of this Patent No. 360,070 is not in use and has not been made since 1887. On this point the testimony of H. H. Westinghouse the General Manager of the Westinghouse Air-Brake Company is conclusive; see Transcript of Record, page 224.

"165 X-Q. Does the Westinghouse Catalogue 1890, "the one now in use, contain any plates or illustrations of 'quick action triple valves' like that shown in the drawings of the Letters Patent No. 360,070?"

"A. It does not.

"166 X-Q. Please state whether or not the type or form of 'quick action triple valve,' which is shown in the drawings of the Patent No. 360,070 was ever illustrated in any catalogue issued by the Westinghouse Air-Brake Company?"

"A. I believe it was not.

"167 X-Q. Is the Westinghouse Air-Brake Company now making and selling 'quick action triple valves' of the type or form shown in the drawings of the Letters Patent No. 360,070?"

"A. They are not."

This device is not in use now, and was abandoned after the trials at Burlington, Iowa, in 1887, because it was *practically unsuccessful*.

The device which *is* in extensive use is the one covered by *another* Patent, No. 376,837, not here in suit. We submit this disposes of the pretension that the patent in controversy is one of great importance and used on 400,000 cars.

The statement of petitioners as to the character of the variance which is ground for a certiorari, is found in the brief, pages 1, 2.

On page 1 of their brief they say:

"When Congress passed the Act of March 3, 1891, establishing Circuit Courts of Appeals, and

in patent cases, made their decisions final, it was anticipated that sooner or later conflicting and irreconcilable decisions would or might be rendered. And obviously, as the effect of such conflicts, a patent valid in one circuit might be invalid in another circuit; and an act of infringement, if committed in one circuit, would be enjoined as wrong, and if persisted in, would be punished as a contempt of court; while in another circuit the same act would be held to be perfectly careful, proper and innocent."

And the petitioners state the alleged variance in their brief, pages 7, 8, as follows:

"The Circuit Court of Appeals for the Fourth Circuit, in the opinion rendered by his Honor, Judge Hughes, says that this Claim 2 is invalid, or, to use the exact language employed, that it is 'fatally defective.'"

Petitioners brief, p. 7.

"This ruling is directly in conflict with a holding of the Circuit Court of Appeals for the Second Circuit. It was there held that this claim 2 of patent 360,070 was valid, and the action of the Court below in awarding an injunction under this claim was affirmed. And this injunction is still in force in the Second Circuit."

Petitioners' brief, p. 8.

From this statement of the alleged variance, the petitioners attempt to impress this Court with the idea that the adjudications of the Courts of the Second and Fourth Circuits on claim 2 of patent 360,070 are so conflicting that if a suit were brought against the Boyden Brake Company, et al, in the Second Circuit the defendants would be enjoined as infringers, whilst if the suit were brought against them in the Fourth Circuit, the bill would be dismissed. This is their contention, stated practically, though they do not use this precise language; *and they are obliged to make out a variance of this kind in order to have even a possible chance for procuring a certiorari.*

Because, if the variance is only formal and trivial and of such a character that no matter which decision is taken, the *result as to the defendants would be the same*, manifestly no such difference of adjudication would exist as would call for the intervention of this Court.

We respectfully insist that the petitioners' brief, in so far as it alleges a variance materially affecting the petitioners' rights against the defendants', is not candid, but is directly misleading.

This Court will find on examination that there is no real variance at all between the two Courts of Appeal, and that the *apparent* variance has nothing in the world to do with the petitioners' rights as involved in this suit.

This alleged variance, even if it exists, is purely formal and immaterial, and the absolute immateriality and triviality of the alleged variance can be demonstrated by an examination of the claims of the patent and a comparison of the decisions which are alleged to be at variance.

In order to better understand the subject matter to which the claims relate, the air-brake will be briefly explained.

MECHANISM OF THE AIR-BRAKE.

The automatic air-brake consists of a train-pipe extending along under the cars, an auxiliary reservoir, a brake-cylinder and a triple valve on each car; the triple valve governing the flow of air between the other devices. The patents on the foregoing devices expired several years ago, and they were public property at the time of filing the bill in this case. The "triple valve," which was old, is *colored blue* in the cuts at the end of this brief. In the year 1887, Westinghouse added to the old triple valve "*an auxiliary valve device*," and procured this patent, 360,070, for the same. This auxiliary valve device of 360,070 is *colored red* in the cut representing this patent at the end of this brief.

Claims 1, 2 and 4, of Patent 360,070, issued to George Westinghouse, Jr., were the special subjects of the suit.

Claim 1 reads:

"In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, a triple valve, and **AN AUXILIARY VALVE** device actuated by the piston of the triple valve and independent of the main valve thereof, for admitting air in the application of the brakes directly from the main pipe to the brake-cylinder, substantially as set forth."

In this claim only the part in bold type was new (colored *red* in cut); the triple valve parts of the combination were old (colored *blue* in cut).

It will be observed that the "*auxiliary valve device*" is the only new element, and that it admits the air from the main pipe to the brake-cylinder. The piston is old and merely actuates the "*auxiliary valve*," and is not the element that does the "*admitting*."

The Circuit Court (Judge Morris) and the Circuit Court of Appeals for the Fourth Circuit both decided this claim to be valid, but they also both decided that there was no infringement, as the defendant's mechanism did not contain an "*auxiliary valve device*," but that Boyden accomplished the same result by giving the *old* main valve of the old triple-valve a *double* function without using any "*auxiliary valve device*" whatever.

Claim 4 is substantially the same as Claim 1. As to these two claims the Circuit Court (Judge Morris) decided, and its decision was affirmed on appeal—

"As by the explicit terms of Claims 1 and 4, Westinghouse has restricted himself as to those claims to an *auxiliary valve* independent of the main valve, I hold that the defendant does not infringe those claims."

Both claims contained as part of the combination "*an auxiliary valve*," and this auxiliary valve was the new thing which made the combinations patentable. The complainant received, therefore, full protection from the Circuit Court of Appeals against any one using such brake

mechanism with an "*auxiliary valve*," but the Court decided, *as matter of fact*, that the device of the Boyden Company did *not* contain any "*auxiliary valve*," and therefore did not infringe the claims Nos. 1 and 4 of the Westinghouse Patent. No variance is alleged as to this part of the decision.

The alleged variance appertains to Claim 2, which reads :

"2. In a brake mechanism the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which, by a further traverse, *admits air directly from the main air-pipe to the brake-cylinder*, substantially as set forth."

All the parts or mechanism named in this claim, including the "further traverse," are old and are shown in blue in the illustrations; the part of the claim in *italics* is a mere *functional* recital or result, and is all that is new in the claim.

It will also be observed that the element, an "auxiliary valve," which is described in the specification as *necessary* to admit the air from the "main air-pipe to the brake-cylinder," is not included in terms in Claim 2 as it is in Claims 1 and 4.

Now, how did the Appellate Courts for the Fourth and Second Circuits respectively treat this claim?

The Court for the Fourth Circuit held this claim *in the form it has*, to be defective. They said:

"We think that when Claim 2 of 360,070, in its language describing the action of that device, fails to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston, '*by a further traverse, admits air directly from the main air-pipe to the brake-cylinder*,' it was fatally defective, claiming only a result which was public property and not identifying the specific means (his own property) by which the result is achieved."

The Court for the Second Circuit affirmed Judge Lacombe's opinion, *per curiam*.

Judge Lacombe construed this claim valid, not in the form in which the claim is expressed, but by reading into it the mechanical means, to wit: *the auxiliary valve device*.

In order to clearly understand Judge Lacombe on Claim 2, it is necessary to advert to his treatment of Claim 1. In regard to Claim 1 Judge Lacombe says:

"The means for actuating the auxiliary valve device is stated in the claim to be 'the piston of the triple-valve,' and the way in which it acts, as shown in the patent, is by direct impingement upon the stem of the auxiliary valve device."

A little further on in his opinion Judge Lacombe says as to Claim 2:

"The discussion of the first claim applies equally to this one. In the first claim actuation by the piston of the triple valve was made an element. In this claim (2) the inventor more *closely limits the mode of such actuation*. It is to be by a 'further traverse' of that piston."

The Court will remember that the first claim contained an "*auxiliary valve*" as an essential part of the patented combination—an auxiliary valve *actuated by the piston*. Judge Lacombe, it will be seen, construes the second claim to be narrower than the first, in this, that whereas, Claim 1 contains an auxiliary valve actuated by the piston, Claim 2 contains an auxiliary valve actuated by "*the further traverse of that piston*." The decree in the New York case was for the complainant because the defendant in that case did use the "*auxiliary valve*."

Now we are in a position to see the *precise effect* of the alleged variance. What possible difference can it make *in the determination of this case* to the petitioners, whether, on the one hand, Claim 2 is declared "*fatally defective*" because it *fails to describe any means* and describes only the result, and thereby the patent fails to hold the defend-

ants, or, on the other hand, is declared valid by reason of *reading into* the claim an element these defendants do not use, an "auxiliary valve actuated by the further traverse of the piston," and thereby also fail to hold the defendants? Whichever view of this *alleged* variance is taken, the defendants, the Boyden Company, are not infringers. As the determination of *this case* would be the *same* under either ruling of Claim 2, there can be no *real* variance, and as the case stands justice has been done.

If Claim 2 is declared "fatally defective," Claim 1 still stands, and if it is declared valid by reading in "an auxiliary valve actuated by the further traverse of the piston," the claim "is more limited" than Claim 1, as held by Judge Lacombe. In Claim 1 the petitioners have more than in Claim 2, even as construed by the Circuit Court of Appeals for the Second Circuit. How are the petitioners hurt by the alleged variance?

By the construction held in the Second Circuit Claim 2 contains an "auxiliary valve." There was not the slightest contention in that case that Claim 2 did not contain an auxiliary valve. On the contrary, since defendants' infringing device (the New York Company) *in that case* did contain an auxiliary valve, there was every reason to *read* an auxiliary valve into the complainant's claim, as was done by that Court.

Counsel for the Boyden Company were perfectly willing to have, and indeed asked, the Circuit Court of Appeals for the Fourth Circuit to adopt the construction of this Claim 2 that was put upon it by the Circuit Court of Appeals for the Second Circuit. (Judge Lacombe's opinion.) We quote from the stenographic report of the oral argument of Mr. Hector T. Fenton, counsel for the Boyden Company, addressed to the Circuit Court of Appeals of the Fourth Circuit, as follows:

"Before discussing the law applicable to functional claims, I shall precede that by a reference to that part of Judge Lacombe's decision in which he discusses this second claim, to see how he treats

its peculiar language, and what mechanism, if any, he reads into it by implication, to make it a claim for a mechanism and not a claim for a mere function. *If your Honors will now apply to this same patent and to this same claim No. 2 precisely the same construction and interpretation that Judge Lacombe gave to it in that case, we shall be perfectly satisfied."*

Surely a "variance" cannot be material to the issue of infringement where counsel for the defendant, the Boyden Company, is willing for the Court to adopt either view!

Now, since it has been decided that as matter of fact the Boyden Company's device did *not* contain an auxiliary valve it was perfectly immaterial for them and to the decision of the case, whether Claim 2 was declared invalid, as the petitioners contend was done by Circuit Court of Appeals for the Fourth Circuit, or valid where an "*auxiliary valve*" is included, as defined by the Circuit Court of Appeals for the Second Circuit. **In either case the decision must be for the defendant.** And yet the petitioners seriously press this alleged "variance" as a ground for invoking the extraordinary and unusual jurisdiction of the Supreme Court of the United States.

In truth, the attempt of the petitioners is simply to get before the Supreme Court by this transparent device, so as to have this Court put on Claim 2 a broad, general construction, to aid them in their future litigation. This Court does not, however, decide *moot* cases, and would not decide on any proposition which does not substantially affect the rights of the parties to the controversy. *Bartemeyer vs. State of Iowa*, 18 Wall., 129.

To show more fully that there is no variance, it must be added that these cases from the Second Circuit were pressed upon the Court for the Fourth Circuit, but that Court decided that this case did not involve the same question.

On this very point at the last part of the opinion the Court for the Fourth Circuit says:

"Here it is contended that the mere use of the extreme traverse of the triple-valve piston to effect the same *functional* result, which was effected by Westinghouse in 360,070 constitutes an infringement, irrespective of the additional means employed. There it was ruled that the use of the extreme traverse *and* of an additional machine the auxiliary valve attached to the original 220,556, which was structurally and *mechanically* equivalent to 360,070 was an infringement of the letters patent. The cases are different and not on all fours with each other, and do not control or affect our own ruling."

As to the other cases in the Second Circuit, e. g., 59 Fed. Rep., 581, and 63 Fed. Rep., 962, *the Patent 360,070 was not in suit*. It is incidentally referred to in construing the subsequent patents of Westinghouse, which were in litigation. In these cases no construction is given to Claim 2 of this patent, nor is any construction given to any of the other claims at all at variance with the rulings of the Court in the Fourth Circuit.

The petitioners, in their brief, do not give the Court the real reason why the device of one defendant, in the Second Circuit, was adjudged to infringe, while the device of the other defendant, in the Fourth Circuit, was held not to infringe.

This result was not due to any conflict or contrariety of decision between the two Courts as to the proper interpretation of the claim, but was due solely to the fact *that the respective devices of the two defendants were totally different from each other*. The Boyden Brake Co.'s device does not contain the invention of the second or any other claim of the Westinghouse patent, as the said claims were defined by either the Court of Appeals of the Second or the Fourth

Circuit, as it does not contain an *auxiliary valve device*. This may be seen at a glance by looking at the illustrations at the end of this brief, in which the *auxiliary valve device* is colored *red* wherever it appears.

The device of the New York Air Brake Co., the Defendant in the Second Circuit, *did contain* the invention as so *defined in all the claims*, as it did have an auxiliary valve device. This may be seen at a glance by examining the illustration of this device, the auxiliary valve device being colored red. (See the cuts at end of brief.)

Hence, the alleged variance is *not* a conflict of decision as to a question of law or the construction of the claim, but a difference of finding of fact on the issue of infringement. In the Second Circuit the Westinghouse invention was compared with a device substantially identical with it, while in the Fourth Circuit it was compared with a device which was totally different from it.

This is not a case of the Circuit Court of Appeals for one circuit rendering a different judgment from that of the Circuit Court of another, *under the same conditions*, which is the test of a variance fixed by this Court.

Columbus Watch Co. vs. Robbins, 148 U. S., 270.

Besides all this, an attentive reading of the whole opinion of the Circuit Court of Appeals for the Fourth Circuit will show that it did not *adjudicate* that Claim 2 was invalid, but only that if *literally* construed it would be "fatally defective" as claiming only a result without specifying the means for attaining that result. This was said in answer to the general and extended construction put upon these literal terms by the lower Court.

In another part of the opinion, however, Judge Hughes is careful to state, speaking of all the claims:

"The phrase substantially set forth" is technical and is equivalent to saying, "by the means

described in the text of the inventor's application for letters patent, as illustrated by the drawings, diagrams and models which accompany the application. These words limit the general terms of the specification which set out the *function* performed by the invention and confine the inventor's rights to his own *means* or their mechanical equivalent of performing the function."

Therefore, the last vestige of this allegation even of a formal variance disappears.

The petitioners state in their brief:

"And the urgency of the case becomes the stronger in view of the fact stated in the "thirteenth" paragraph (p. 5) of the petition herein, that there are other causes involving this claim, unheard and undecided, and more particularly one in the Eastern District of Missouri."

Brief pp 8 and 9.

This statement of "urgency" is conclusive of the weakness of the petitioner's case, for it is perfectly manifest that in the pending Missouri case, if the defendant there has an "auxiliary valve device," he will be enjoined; if he has *no* "auxiliary valve device," the bill will be dismissed; and these results will be reached equally by the citation of the decision in the Fourth Circuit or that of the Second Circuit.

(C.) SECOND ASSIGNMENT OF ERROR.

The second assignment of error is discussed by the petitioners in their brief, pp. 10-14.

The error alleged is that the Circuit Court of Appeals for the Fourth Circuit decided that claim 2 of patent 360,970 was "fatally defective," whereas the decision of the Court for the Second Circuit was manifestly correct.

Brief, p. 10, p. 12.

Without further arguing the matter we simply suggest the following conclusive answers to this assignment:

1. The Circuit Court for the Fourth Circuit did not so adjudicate.

2. Even if they did so adjudicate and such decision is error, the errors would not be ground for reversal, for by such alleged error the complainants could not have been prejudiced, as we have already fully argued. The petitioners concede that the decision in the Second Circuit is right, (brief-6-12) and we have shown that there is no material difference between this decision and that rendered in the Fourth Circuit, so far as the Complainants rights against these Defendants are concerned.

Lancaster vs. Collins, 115 U. S. 222.

3. *A fortiori*, this error, even if it exists, would not, in the absence of the *right* of appeal be any ground for certiorari.

This question is fully discussed in the first part of this brief. We call the Court's attention in passing to the inconsistency of the petitioner's own argument. On page 12 of the brief the petitioners concede that the decision of the Court in the Second Circuit was correct. That Court declared claim 2 of 360,970 to be valid, by reading into its general terms "*an auxiliary valve*." And yet on page 11 of this brief the petitioners endeavor to read into this claim 2, not "*an auxiliary valve*" as did the Court for the Second Circuit, but a "*suitable valve*," which is directly at variance with the decision in the Second Circuit.

It is interesting to note in this connection that the patent office "File Wrapper" of the patent in suit contains an explanatory letter written by the Attorney when asking for the allowance of claim 2, after it had been rejected by the official Examiner of the Patent Office. In this letter urging that the claim be allowed the Attorney interprets the meaning of claim 2 as follows:

"When, however, the triple-valve is provided with an '*auxiliary valve*' operated by its piston, which performs a new function additional to that of the triple-valve as previously employed, it is believed that *such* combination is wholly novel."

Record, p. 1175, top of page.

(D) THIRD ASSIGNMENT OF ERROR.

This assignment is discussed in petitioner's brief from page 14 to page 22.

In substance, the alleged error consists in this—that the Court in considering the fact that the Patent Office, after full examination, awarded a patent to Boyden on August 16, 1892, decided "that action by the Patent Office was, in effect, a ruling that the Boyden device did not infringe patent 360,070," and takes rank as the testimony of experts of the highest experience, skill and knowledge of mechanics.

Without following the Complainants through the long argument by which they endeavor to show that this ruling was erroneous, we suggest the following answers to this assignment:

1. The petitioners seem to forget that they are discussing a case of application for Certiorari, and argue the matter as if they were before this Court on appeal as a matter of right. Even if we should concede that this alleged ruling of the Court was an error, which we do not, it would not furnish any *ground* for Certiorari, as we have fully argued in the first part of this brief.

2. Suppose the petitioners were before this Court on appeal *as of right*, this alleged error would not be even a ground for reversal. It forms simply a part of the *reasoning* of the Court of a corroborative character, and the *reasonings* of a Court are no part of its rulings and are not the subject of appeal.

Bell vs. State, 57 Maryland, 116.

The ruling of the Court for the Fourth Circuit on this question is found in the following language of its decision:

"Comparing the two devices apart from the triple-valve piston in extreme traverse, we are unable to entertain a doubt that the ruling of the Patent Office was correct to the effect that Boyden's device was *not the mechanical equivalent* of that of Westinghouse. They seem to us to differ as widely from each other as two devices for accomplishing the same result can well differ."

The Court will observe that this ruling that Boyden's device was *not* the mechanical equivalent of the device of Westinghouse is reached by the Circuit Court of Appeals from a *comparison* of the two devices. That is their conclusion from the comparison. The ruling of the Patent Office is referred to simply as corroborating their opinion. It is evident that such would have been their opinion entirely independent of what the Patent Office did. Whether their reference, *arguendo*, to the effect of the Patent Office ruling, in this case, be right or wrong, the question, so far as the rights of the Complainants and the Defendants are concerned, becomes a mere *abstract* question. It may be important to decide these abstract questions of practice, in the workings of the Patent Office; but they cannot be made the ground for an appeal, and a *fortiori* not a ground for *certiorari* in an actual litigation, when the rights of the parties are not essentially involved in the proper decision of the question.

3. But the decision of the Court was right, though its language might have been a little more explicit. Ordinarily, in a proceeding for infringement, a later patent issued to the Defendant for the machine in question, is not admissible in evidence, on the ground that it is irrelevant to the issue made up in the pleadings, which is merely that of the validity of the patent in suit, and the similarity or dissimilarity of the Defendants' machine with that of the patent alleged to have been infringed thereby. The reason

is that a posterior patent could not justify an infringement of a prior one for the *same machine*. In this case the later patent and the ruling of the Patent Office were simply set up as corroboratory evidence that the Defendants' device, described and claimed in it, "*differs essentially*" quoad the part or improvement claimed in the prior patent from the machine of such prior patent. The Boyden patents and the quasi judicial finding of the Patent Office were used in corroboration to show that the device described and claimed in the later patents to the Defendants is *not the mechanical equivalent* for, or an improvement on, the device described and claimed in the earlier patent of Complainants, and that the devices of the two patents are distinct and different inventions, constructed and operating on different principles, though producing the same result.

This is the only use made by the Court of the Patent Office ruling, and in making this use of it the Court was undoubtedly right.

Miller vs. Eagle Co., 151 U. S., 186.

Corning vs. Burden, 15 How., 252.

Robinson on Patents, vol. 3, s. 1016:

(E) FOURTH AND FIFTH ASSIGNMENT.

These assignments require no special argument, as the reasons urged in this brief against the prior assignments apply with equal force to these assignments.

The Defendants, having fully answered all the various assignments and reasons given by the petitioners for the writ of Certiorari, respectfully insist that the petition should be dismissed, with costs and the application for the writ denied.

CROSS-APPEAL.

BRIEF FOR DEFENDANTS.

STATEMENT OF THE CASE.

This suit, for an injunction and account, was commenced December 12, 1889, in the Circuit Court for the District of Maryland, by George Westinghouse, Jr., and the Westinghouse Air-Brake Company, Complainants, against the Boyden Power Brake Company, George A. Boyden, President, Charles B. Mann, Secretary, William Whitridge, Treasurer, and the Boyden Brake Company, (the original company having been reorganized under

the latter name), Defendants, charging the Defendants with infringing the *first*, *second* and *fourth* claims of the patent issued to George Westinghouse, Jr., March 29, 1887, No. 360,070, for Improvements in Fluid-Pressure Automatic Brake Mechanism. Several years were spent in getting the case ready for trial, and finally it was argued before his Honor Judge Morris, at Baltimore, in November, 1894, and decided by him March 11, 1895 (66 Fed. Rep., 997.)

Judge Morris held, in substance, that the Boyden brake, the alleged infringing device, does not employ the "auxiliary" or "emergency" valve of the Westinghouse patent or any mechanical equivalent thereof, and, therefore, does not infringe the *first* and *fourth* claims, in which that element is expressly mentioned; but that the *second* claim of said patent, which is silent as to that element, is entitled to cover *functional equivalents*, or, in other words, *results*, and, in that view of the case that this claim was infringed.

The Defendants appealed from so much of the decree as held them to have infringed the *second* claim; and the Complainants appealed from so much of the decree as held that the Defendants had not infringed the *first* and *fourth* claims.

On November 11, 1895, the United States Circuit Court of Appeals for the Fourth Circuit, sitting at Richmond, Va., rendered a decision (17 C. C. A., 430) affirming Judge Morris' decision on the *first* and *fourth* claims, but reversing it on the *second* claim, and directed the bill of complaint to be dismissed, which was done in obedience to its mandate. The Complainants then applied to this Court for a writ of *certiorari*, which was issued on January 30, 1896. Subsequently, on the petition of the Defendants, the case was advanced.

The only question to be determined is the question of infringement.

The invention in controversy consists in *mechanical means for producing a certain result which, in the air-brake art, is technically called "quick action."* The subject-matter of the patent in suit is comparatively simple, provided an intelligent understanding be first acquired of the air-brake mechanism as it existed prior to the date of said patent, March 29, 1887. We therefore, at this point, give a brief explanation of the development of the air-brake.

FOLDOUTS TOO LARGE TO
BE FILMED

STATE OF THE ART.

DIRECT OR STRAIGHT AIR-BRAKES.

(See illustration.)

In the early forms of air-brakes the locomotive was provided with an air-pump, a reservoir, an engineer's brake-valve and pipe connections, and the cars were each provided with a pipe extending lengthwise (commonly called the "train-pipe,") which at each end of the car has flexible hose and couplings, and a brake-cylinder containing a piston and rod. The operation of the above elements was as follows:

The air-pump compressed the air, which was stored in the reservoir ready for use, the engineer's brake valve preventing it from passing to the train-pipe and brake-cylinder on the cars.

To apply the brakes the handle of the engineer's brake-valve was turned to permit the stored air in the reservoir to pass to the train-pipe and direct to the brake-cylinders on the cars, and exert its force on the pistons therein, which in turn transmit the power to the brake-shoes and press them against the wheels by suitable intervening levers and rods, and thereby apply the brakes.

To release the brakes the handle of the engineer's brake-valve was shifted to its former position, permitting the air in train-pipe and brake-cylinders to be discharged to the atmosphere, thus releasing the brake-shoes from the wheels.

The "straight air" brakes were seriously defective in practical operation, because, if the train-pipe or connecting hose became ruptured, or uncoupled, the brakes could not be applied, for the reason that, under these conditions, when compressed air from the reservoir was admitted to the train-pipe the said air would escape to the atmosphere, and would not therefore operate the brakes, or, if the brakes were already applied, they would instantly be released when such rupture occurred.

AUTOMATIC AIR-BRAKES.

(See illustration.)

To remedy the inherent defect referred to of the "straight air-brakes," a new system known as the "automatic air-brake" superseded the "straight air." In the automatic air-brake system the locomotive is provided with the same devices as

were used with the "straight air-brake," and in addition each car is provided with a storage reservoir (called the "auxiliary reservoir," because it is auxiliary or additional to the main reservoir on the locomotive) and with a *valve device* termed a "triple valve," arranged at the juncture of the train-pipe, the auxiliary-reservoir and brake-cylinder, its functions being to transmit the air-pressure to and from the above devices in applying and releasing the brakes.

The essential elements of an automatic air-brake are :

- | | | |
|---|---|--|
| 1. Air-pump, | } | These made up the
"straight" air-brake. |
| 2. <i>Main</i> reservoir on locomotive, | | |
| 3. Engineer's brake-valve, | | |
| 4. Train-pipe, | | |
| 5. Brake-cylinder, | } | These were added to
make the "automatic." |
| 6. Auxiliary-reservoir on car, | | |
| 7. Triple valve. | | |

The Mode of Operating the engineer's brake-valve to apply and release the automatic brakes is the reverse of that employed with the "straight air-brake," that is to say, when the "automatic brakes" are to be released, the engineer's brake-valve admits air to the train-pipe, which passes to and effects the triple-valve on the car so that the air from the train-pipe passes into the auxiliary-reservoir, and at the same time discharges the air in the brake-cylinder to the atmosphere to release the brakes, and when they are to be applied said brake-valve discharges the air from the train-pipe, which again effects the triple-valve, so that the air stored in the auxiliary-reservoir passes to the brake-cylinder.

By the Invention of the "Automatic" the serious objection of the straight air-brake was overcome, because, if the train-pipe of the automatic should rupture, or the hose-coupling become disconnected, and thus accidentally allow the air therein to escape, the compressed air in the auxiliary-reservoir would at once be *automatically* admitted to the brake-cylinder and apply the brakes in the same manner as though the air were intentionally discharged at the engineer's brake-valve—hence the term "automatic" was applied to this form of air-brake.

BLEED, THROUGH POOR COPY

Simple Form of Triple Valve.

The diagrams below show the Train Pipe, the Auxiliary Reservoir, the Brake Cylinder and the Triple Valve of the "Automatic Brake" in a *simple* form in order to graphically define the philosophy involved.

Fig. 1.

This cut shows the Triple Valve in the position to charge the Auxiliary Reservoir ready for use. The course of the air from the train pipe to the auxiliary reservoir is shown by the red line passing through the port of the feeding-in valve colored blue.

Fig. 2.

This cut shows the Triple Valve in the position to apply the brakes. The course of the air from the auxiliary reservoir to the brake cylinder is shown by the red line passing through the port of the main valve in solid black.

Fig. 3.

This cut shows the Triple Valve in the position to release the brakes. The course of the air from the brake cylinder to the atmosphere is shown by the red line passing through the port uncovered by the release valve colored green.

PHILOSOPHY OF THE TRIPLE-VALVE.

The functions of the triple-valve are, first, to charge the auxiliary-reservoir with compressed air from the train-pipe, and thus put the brakes in condition for use; second, to admit auxiliary-reservoir air to the brake-cylinder when it is desired to apply the brakes; and third, to discharge the compressed air from the brake-cylinder to the atmosphere when it is desired to release the brakes.

On the opposite page are inserted diagrams showing the train-pipe, auxiliary-reservoir, brake-cylinder and the triple-valve in a *simple* form in order to graphically define the philosophy involved, which is as follows:

To charge the brakes with air ready for use, the air from the train-pipe passes through the feeding-in-valve (colored *blue*) and thence to the auxiliary-reservoir where it is stored ready for use. The course of the air is shown by red line, Fig. 1.

To apply the brakes, the air is discharged from the train-pipe, and the expansion of air in the auxiliary-reservoir, causes the feeding-in-valve (colored *blue*) to close, and the main-valve (colored *solid black*) to open, which permits the air stored in the auxiliary-reservoir to pass through the main valve port to the brake-cylinder, and force out the piston rod, *A*, and thereby apply the brakes. The course of the air is shown by red line, Fig. 2.

To release the brakes, the air is again admitted from the train-pipe which causes the release-valve (colored *green*) to open and discharge the air from the brake-cylinder to the atmosphere, thereby releasing the brakes. The course of the air is shown by the red line, Fig. 3.

It will be seen that there are three functions involved in the operation of the triple-valve, hence the term "triple-valve," as used in connection with the automatic air-brake.

TRIPLE-VALVE OF PATENT 220,556.

"The triple-valve," as exemplified in the Westinghouse patent No. 220,556, October 14, 1879, and, in that form extensively used since, should be thoroughly understood before entering upon a discussion of the matters in controversy in the present suit.

The casing of the triple-valve (see cuts opposite the following page) is provided with a connection to the train-pipe, one to the auxiliary-reservoir and one to the brake-cylinder. The valves of this device are as follows:

First. The feeding-in valve, formed by part of the piston *G* (colored blue), whose *function* is to open a port *a* to admit compressed air from the train-pipe to charge the auxiliary-reservoir ready for use.

Second. The sensitive graduating-valve *e*¹ (colored yellow), whose *function* is to govern a port in the main valve *H* to admit auxiliary-reservoir air to the brake-cylinder in graduated amounts to partially or slowly apply the brakes.

Third. The release-valve *s* (colored green), whose *function* is to open a port to discharge the compressed air from the brake-cylinder to the atmosphere to release the brakes.

Fourth. The main valve *H* (colored solid black), whose *function* is to fully open a port *C* to admit auxiliary-reservoir air to the brake-cylinder quickly, in case it is desired to apply the brakes quick and stop the train *for an emergency*.

While four valves are embodied in this triple-valve 220,556, there are only three *functions*, because the *second* valve (yellow) and the *fourth* valve (black) perform the same *kind* of function, and differ only in the *degree* or manner of performance.

The piston *G* reciprocates in a cylinder, and *its function* is to *actuate* the several above-mentioned valves; the piston and its stem in the cut are etched with heavy lines to readily distinguish those parts from the casing, which are etched with lighter lines.

The operation of the "triple-valve" is as follows: To charge the brakes in readiness for use the engineer admits compressed air from the main reservoir on the locomotive to the train-pipe, the effect of which is to move the triple-valve piston *G* to the position shown in Fig. 1 (see cut opposite page), and thereby open the feeding-in-valve (*blue*). The air then passes from the train-pipe to the auxiliary-reservoir, its course being shown by the red line in Fig. 1. This reservoir is usually charged (as a maximum) with 70 pounds of air-pressure to the square inch.

To apply the brakes gently or by graduated application, in order to slack the speed of the train or to stop at a station, the engineer discharges a small amount of air from the train-pipe, which slightly lowers the pressure on the train-pipe side of the piston *G*, and the then higher pressure on the auxiliary-reservoir side causes the piston *G* to make its *preliminary traverse* which places it in the position shown in Fig. 2—against the abutting

Triple Valve Device of Patent 220,556.

Fig. 1.

This cut shows the Valves and Piston **G** in the **Charging Position**, as used in 1. The course of the air in charging the Auxillary Reservoir is through the Port **a** shown by the Red line.

Fig. 2.

This cut shows the "**preliminary traverse**" of the Piston **G** and the Gradual Valve **a** and Main Valve **H** in position for graduating and service stops, as used in 1. The course of the air from the Auxiliary Reservoir to the Brake Cylinder is through

Triple Valve Device of Patent 220,556.

Fig. 3.

This cut shows the Valves and Piston **G** in the **Release Position**, as used in 1879. The course of the air is from the Brake Cylinder to the atmosphere through the Port **s**, shown by the Red line.

Fig. 4.

This cut shows the "**further traverse**" of the Piston **G** with the Main Valve **H** in position for an emergency stop. The Port **C** thereby being opened to its full capacity to admit air to the Brake Cylinder quickly, as used in 1879. The course of the air from the Auxiliary Reservoir to the Brake Cylinder is through the Port **C** opened by the Main Valve **H**, shown by the Red line.

stem b^1 , which arrests its movement. The function of this "preliminary traverse" of the piston is to close the release-valve (*green*) and open a port through the main valve H (*solid black*), which is governed by the sensitive graduating valve e^1 (*yellow*); this permits the auxiliary-reservoir air to pass to the brake-cylinder (the course of the air is shown by a red line, see Fig. 2), until the pressure in the auxiliary-reservoir is reduced below that existing in the train-pipe, the latter pressure, then preponderating, moves the piston back, which causes the graduating valve e^1 (*yellow*) to close the port through the main valve H (*solid black*), and thereby prevent any additional air from entering the brake-cylinder and holds the brakes partially applied. If an increase of braking pressure should be desired this graduating operation must be repeated.

To release the brakes the engineer re-establishes the maximum pressure (70 pounds) in the train-pipe, which moves the triple-valve piston G to the former position, and thereby opens the release-valve (*green*) so that the air will be discharged from the brake-cylinder to the atmosphere (the course of the air is shown by a red line in Fig. 3), and at the same time communication is established through the feeding-in-valve (*blue*) between the train-pipe and auxiliary-reservoir whereby the latter is recharged for future use. (See Fig. 1.)

To apply the brakes fully and as quickly as possible for an emergency in case of an accident, a greater amount of air is discharged by the engineer from the train-pipe than is required for merely partially applying or graduating the brakes. This *greater* reduction of pressure in the train-pipe causes the piston G of the triple-valve to make its full or *further traverse*, which forces the abutting stem b^1 to the right, as shown in Fig. 4. The function of this full or "*further traverse*" is to move the main-valve H (*solid black*) to fully open the port C to allow the auxiliary-reservoir air to quickly pass to the brake-cylinder and apply the brakes quickly (the course of the air being shown by a red line—Fig. 4) or in a briefer space of time than can be done through the graduating-valve e^1 (*yellow*) actuated by the *preliminary traverse* of the piston.

It is therefore seen that a "triple-valve," prior to the patent in suit, as exemplified in patent No. 220,556, dated October 14, 1879, consisted of four valves, namely, the feeding-in-valve (*blue*), the graduating-valve (*yellow*), the release-valve (*green*),

and the main-valve (*solid black*); and also it is seen that the said valves were actuated by a piston *G*, which had a preliminary traverse and a full or further traverse. It will also be noted that when *applying the brakes*, auxiliary-reservoir air may be admitted to the brake-cylinder by either one of two separate valves, to wit, the graduating-valve *e*¹, (*yellow*, see Fig. 2), for ordinary service work, or the main-valve *H* (*black*, see Fig. 4), for emergency work.

The form of triple-valve above described, and shown in the Westinghouse patent of October 14, 1879, No. 220,556, was the result of a series of improvements successively engrafted upon the original crude automatic air-brake patented by Mr. Westinghouse March 5, 1872, No. 124,404.

DEVELOPMENT OF THE TRIPLE-VALVE.

In his first improvement, patent August 12, 1873, No. 141,685 (p. 736), he invented the original form of triple-valve corresponding in principle to those which have since made the automatic air-brake successful and famous. In this original device, *the main valve*, which admits air from the auxiliary-reservoir to the brake-cylinder to apply the brakes, *was of the poppet form*, and, as a poppet-valve can govern only one port, separate valves had to be provided for feeding-in the air from the train-pipe to the auxiliary-reservoir, and for discharging the air from the brake-cylinder to release the brakes. The three separate valves constituting the triple-valve were actuated by a flexible diaphragm (the equivalent of a sliding piston.) The main valve was provided with a tapering plug, *a*, for graduating purposes, and was capable of admitting air rapidly or slowly from the auxiliary-reservoir to the brake-cylinder, according as the engineer caused the diaphragm (or piston) to be moved through its entire traverse or only through a portion of its traverse. This patent, therefore, contained the germ and principle of everything that is to be found in the later patent of October 14, 1879, No. 220,556.

In patent of October 28, 1873, No. 144,006 (p. 740), Mr. Westinghouse improved upon his prior devices by substituting a sliding piston for the flexible diaphragm, *by providing a check-valved air-passage through the piston for charging the auxiliary-reservoir*, and by making some changes in the form of the main

valve and the release valve, still, however, retaining *the poppet form of the main valve*.

May 11, 1875, C. H. Perkins, assignor to George Westinghouse, Jr., No. 163,242, and August 3, 1875, W. D. Jones, No. 166,386, (p. 745), and H. L. Perrine, No. 166,405 (p. 749), further improved the triple-valve by substituting a sliding piston-valve for the poppet form of main valve previously used by Mr. Westinghouse. This enabled a single sliding member to perform the feed-valve function of admitting air from the train-pipe to the auxiliary reservoir, the main-valve function of admitting air from the auxiliary-reservoir to the brake-cylinder to apply the brakes, and the release-valve function of discharging air from the brake-cylinder to release the brakes.

Mr. Westinghouse immediately saw the advantages of the slide-valve, and was quick to appropriate them to his own use by improving the form of its embodiment. He decided that a piston actuating a slide-valve was preferable to a piston-valve; and, October 5, 1875, took out an important patent, No. 168,359 (p. 752), covering this improvement. In the latter patent the piston itself (marked *G*), is made to operate as a feed-valve in connection with the small lateral passage *s*, while the main-valve function and release-valve function are lodged in a large slide-valve *H* held between two fixed collars on the piston stem and, therefore, moving with the piston. The piston is adapted to move through a portion of its traverse to partially open the main port *e* for graduating the brake-pressure, and through its entire traverse to fully open said port when necessary to apply the brakes with full pressure in the shortest possible time. The release of the brakes was effected through a recess in the face of the main-valve *H*, which, when the apparatus was in normal running position, connected the exhaust port, *e'* with the passage leading to the brake-cylinder. In the first part of its stroke to apply the brakes, the piston moved without opposition; but to complete its full traverse it had to overcome the resistance of a spring-controlled stem *d'*; provided, as the patent states, "in order to render this operation of graduating the air-pressure in the brake cylinders more easy and certain," that is to say, in order to enable the end of the main-valve *H* with greater certainty to partially uncover the port *e* for graduating purposes, and to wholly uncover said port when sudden danger

or "emergency" required the quickest and strongest possible application of the brakes.

In patent of January 11, 1876, No. 172,064 (p. 752), Mr. Westinghouse reverted to the type of feed-port first found in his patent of October 28, 1873, No. 144,006 (p. 740), namely, by a passage *through* the triple-valve piston. He contrived a small stem or needle-valve, *c*, to govern said feed-port, and, by making the main-valve a little shorter than the distance between the two collars which actuate it, he gave the piston a slight degree of "lost motion" with respect to the main-valve, thereby enabling the needle-valve to close the feed-port without disturbing the main-valve.

Three years experience with the triple-valve as thus far perfected demonstrated that, while it was of great utility and value, it was not sufficiently *sensitive* to graduate as perfectly as was desirable. The reason of this was, that the large exhaust recess in the face of the main-valve caused the air-pressure behind the latter to press it strongly against its seat (see testy. of H. H. Westinghouse, p. 324, Ans. 550), so that considerable force was required to slide it, and that, after the brakes were set by graduation, if a force was applied sufficient to overcome the friction and slide the valve back far enough to close the passage to the brake-cylinder, in order to hold them set, it was liable to slide it clear to the inner end of its traverse, open the release-port, and thus accidentally release the brakes instead of holding them set. Mr. Westinghouse set himself at work to remedy this defect, and the result of his efforts appears in patent No. 220,556, dated October 14, 1879 (p. 762).

In this patent, he retained the "lost motion" of patent No. 172,064, and used it to operate a small sensitive graduating-valve *e*¹, working in a passage formed in the main-valve *H*, so that in graduating, the piston could cause the sensitive valve to open and close its port without disturbing the main-valve. This *sensitive graduating-valve* substantially perfected the Triple-Valve for ordinary passenger service, and has been used in one form or another, on all air-brakes since 1879. A complete description of its operation has already been given in this Brief on pp. 5, 6, 7 and 8.

TWO TRAVERSES OF THE PISTON—OLD.

In all the triple-valves above mentioned, the piston (or

diaphragm) was capable of a "preliminary" or partial traverse, for graduating purposes, and a "further" or complete traverse, for emergency purposes. By its partial traverse, the triple-valve partially opened the passage from the auxiliary-reservoir to the brake-cylinder and applied the brakes slowly; by its complete traverse, it opened said passage to its full capacity and applied them quickly with full force. The specification of patent No. 220,556 (p. 764, near the bottom) refers to the use of the partial traverse for graduating purposes, saying: "When now the valve *H* is thus shifted, so that the port *s*¹ shall, to the extent of one-quarter or one-half its capacity, more or less, *as is usual when less than a maximum breaking force is desired*, be thus brought into communication with the port *C*," etc., etc. The specification of patent 168,359 (p. 754, near the bottom) refers to the same subject in these words: "Hence the piston *G* may be brought down so that while entirely closing the supply-port *s* it shall bring the valve *H* to a position where it shall uncover only a small part of the port *e*, *or any desired part*." The specification of the original triple-valve patent No. 141,685 (August 12, 1873), indicated this operation as follows (p. 738, near the middle.):

"The area of the opening through the port *o*¹ is regulated *by the distance which the plug *o* is caused to move vertically upward*. * * * By the use of the "taper plug *o*, in the manner described, and by regulating, as can easily be done by the use of suitable cocks, "the amount of pressure in the upper and lower parts of "chamber *G*¹, it is easy to regulate the amount or density "of the air which is permitted to flow through the port "o¹ into the brake-cylinder, and consequently easy to "regulate and adjust, at all times, the force with which "the brakes are applied, *and such force may be varied "from the maximum power of the brakes down to the "fractional part of a pound in excess of ordinary "atmospheric pressure*."

Mr. H. H. Westinghouse, testifying as to the triple-valves in use prior to 1886, said (p. 123, near bottom):

“And all the operations of supplying the auxiliary reservoir, admitting air to the brake-cylinder of limited pressure, and of discharging the air from the brake-cylinder for the purpose of release, are performed by a *partial* movement of the piston and valve mechanism of the triple valves. It is only for ‘emergency’ operations or quick stops that the *final and complete* movement of this piston and valve is required. This final movement is obtained by a rapid and considerable reduction of pressure in the train-pipe, as compared with what is required for ‘service operations.’”

In the statement of facts preceding its opinion in this case, the Circuit Court of Appeals said:

“In the Westinghouse automatic air-brake, as patented in No. 220,556, the ordinary work of braking was performed by a partial traverse of its chamber by the triple-valve piston, graduated, according to the purpose desired, at the will of the engineer; and emergency work was done by an extreme traverse of the piston to the end of its chamber. It may be observed that the automatic air-brake, patented as No. 220,556, which embraced all previous improvements, is now free to public use, the patent having expired and ceased to be confined to the exclusive use of its inventor.”

TRIPLE-VALVE DEFECTIVE ON LONG TRAINS.

The triple-valve, thus slowly evolved from the original form of patent No. 141,685, August 12, 1873, to the highly improved form of patent No. 220,556, October 14, 1879, and in the latter form used by the complainants without further material improvement till the year 1888, was satisfactory for short trains consisting of eight or ten cars or less, but on long trains consisting of forty or fifty cars or more, it was not only unsatisfactory, but absolutely impracticable; *and its impracticability resulted from the very fact that the piston had the two traverses* referred to by Mr. H. H. Westinghouse at the bottom of p. 123, namely, a partial traverse for graduating purposes, and a full traverse for emergency stops.

The defective operation of the brakes occurred *only when making emergency stops*—their operation in graduating being entirely satisfactory. The cause of the trouble was as follows :

In making an emergency stop, the engineer throws his controlling valve wide open, allowing the air to escape from the train-pipe at the engine with the utmost possible speed. A great reduction of air-pressure instantly takes place in the forward end of the train-pipe, and travels back like a wave towards the rear end of the train. As it reaches the triple-valve of the first car, it causes the piston and main valve to be forced through their entire traverse, thereby suddenly opening to its full capacity the port or passage leading from the auxiliary-reservoir to the brake-cylinder and almost instantly applying the brakes with full force. The result is, that the first car is suddenly checked in its speed before the wave of train-pipe pressure reduction has had time to reach the second car and set brakes thereon ; and the second car runs forward at full speed and bumps against the first car, whose speed has already been checked. The same thing takes place between the second car and the third, the third and the fourth, and so on throughout the train. In other words, the brakes would apply on the forward cars of the trains in an appreciable time before they applied on the rear cars, thus checking the forward end of the train to such an extent that the rear cars would run into them, causing serious results from the collision. (See testy. of H. B. Stone, p. 136, ans. 51.) The effect is about the same as striking a precipice. Oftentimes the rear cars have been completely demolished by such a collision.

In *graduating*, however, the train-pipe pressure is but slightly reduced ; the piston and main-valve execute only a partial traverse ; the port leading from the auxiliary-reservoir to the brake-cylinder is only partially and momentarily opened ; the air flows slowly in'to the brake-cylinder ; and before the brakes effectively check the first car they are already commencing to apply on the second car. Hence, no "shock" is produced, and the train quietly and smoothly reduces its speed or gradually comes to a full stop.

The Circuit Court of Appeals said (p. 879) :

"That machine, 220,556, was designed both for graduated braking and for emergency braking. The former

“was provided in the sensitive valve inserted in the stem
 “of the triple-valve piston, through which compressed
 “air was vented at the will of the engineer from the
 “auxiliary-reservoir into the brake-cylinder. But this
 “earlier and expired patent contained more than the
 “sensitive valve in the stem of the piston, and more
 “room in the piston chamber than was necessary for a
 “partial traverse of the piston. It contained a main
 “valve and a sufficient prolongation of the piston cham-
 “ber for the extreme traverse. This main-valve and this
 “prolongation of the chamber were entirely useless for
 “graduated work, and were intended and employable
 “only for emergency work.”

The triple-valve of patent 220,556 and its predecessors were, therefore, well adapted for short trains, but for long freight trains they were practically useless; and in air-brakes used on *freight trains*, Mr. Westinghouse was obliged to omit the emergency port and abandon the attempt to make quick emergency stops (see testy. of H. H. Westinghouse, p. 142, Ans. 133.) With the emergency port thus omitted, a large reduction of train-pipe pressure holds the graduating port open long enough to gradually charge the brake-cylinder with full pressure, but so slowly that the train, if moving swiftly, necessarily must run a considerable distance before stopping.

This was a serious defect in freight brakes. The power to make a quick emergency stop is of extreme importance to the safety of life and property. The question, therefore, arose: “How can both the graduating function and the emergency stop of patent 220,556 be retained and used, and yet the emergency stop be effected without producing fearful shock?” This was the problem to be solved.

INVENTION OF MEANS TO QUICKEN THE APPLICATION OF BRAKES.

It was known that the “shock” was occasioned by the interval between the sudden application of the brakes on successive cars, and that if this interval could be shortened so that the brakes would begin to set on the second car before they had checked the first car, there would be no shock. A French engineer had discovered and demonstrated that if all the

triple-valves along the train be operated simultaneously, by means of an electric current controlled by the engineer, no shock is produced even in the most sudden emergency stop. The use of electricity for the purpose was objectionable, and it became desirable, therefore, that other means should be discovered for reducing the intervals occurring in the serial application of the brakes. Mr. Westinghouse turned his attention to this subject as early as 1879, and then conceived the idea that if the engineer could vent the train-pipe not only at the locomotive but *also under each car*, the serial application of the brakes could be greatly quickened, because the train-pipe air would escape at the *nearest* opening, instead of traveling to the locomotive, and thus the reduction of train-pipe pressure from one end of the train to the other, would be greatly expedited. This idea he embodied in patent No. 217,838, dated July 22, 1879, wherein he set forth the principle in the following language :

"It sometimes happens with such brake apparatus, *especially in case of accident*, that material advance could be effected by having all the brakes of the train applied or brought into action *simultaneously, or as nearly so as possible*. To accomplish this it is only necessary to make provision for the *simultaneous opening of one or more ports in the air-conduit passages at points not remote from each auxiliary reservoir*. For this purpose I arrange at such various parts of the air-conduit or communicating pipes as may be desired, but by preference at the couplings, relief-valves of the kind shown in the drawings."

He did not put this invention into general use on the railroads ; but, during the taking of the evidence in this cause, the Defendants demonstrated by actual tests of 50 brakes that the apparatus of the 1879 patent accomplishes all that Mr. Westinghouse claimed for it, reducing the time of applying the brakes on the rear car from twelve seconds down to six.

June 26, 1883, George A. Boyden, one of the Defendants, took out a patent, No. 280,285, in which the triple-valve not only controlled the admission of air from the train-pipe to the auxiliary-reservoir and from the auxiliary-reservoir to the

brake-cylinder, but also contained a check-valved passage leading from the outer end of the triple-valve piston-chamber to the main-valve chamber, so that compressed air could be transmitted directly from the train-pipe to said valve-chamber, and thence to the brake-cylinder, to augment the pressure of the brakes.

Such was the state of the art at the date of the invention in controversy in 1886.

GENESIS OF THE WESTINGHOUSE QUICK-ACTION AIR-BRAKE.

In 1885 the Master Car Builders' Association, an organization composed of those having charge of the construction and maintenance of car equipment upon railroads in the United States and Canada, and also those engaged in the manufacture of cars for sale, appointed a committee to investigate the relative merits of several brakes that were represented by their owners as suitable for general use upon freight cars. (H. H. Westinghouse, p. 117, Ans. 47.) This led to a series of tests in July, 1886, in Burlington, Iowa, a second series of tests in May, 1887, at the same place; and a third test at the same place in the fall of 1887, followed by the exhibition of a train of cars by the Westinghouse Air-Brake Co. on various railroads in the United States during the same fall. A full history of the matter is given by Mr. H. H. Westinghouse, in his answer 47 (pp. 117-135), and by Mr. H. B. Stone, in his deposition (pp. 135-138). The history is briefly as follows:

The test of July, 1886, on trains composed of fifty cars, demonstrated that air-brakes *in which the valves are actuated by electricity* effect an emergency stop without "shock;" but that air-brakes of the type of patent No. 220,556, in which electricity was not employed, and in which it took an average of 12 seconds to apply the brakes on the rear car, produced destructive and dangerous shocks. The degree of shock was measured by an instrument called a slidometer, in which an indicator was, by the stopping of the train, caused to slide to a distance proportionate to the force of the shock. Shocks of 12 inches were sufficient to injure live stock and equipment; repeated shocks of from 12 to 20 inches were sufficient to start

the loads, at the rear end of the train, through the ends of the cars; a shock of 63 inches broke the train in two, and nine of the rear cars, although loaded with special care and the loads protected by timber, had their ends broken and bulged out, by the shifting of the loads, to such an extent that they were in a dangerous condition (p. 119). The committee reported in favor of the air-brake which had its valves actuated by electricity; but doubted the reliability of electricity for practical use, and recommended further investigation (pp. 126, 127). The result was, the second series of tests on 50-car trains, which commenced May 13, 1887.

The test of July, 1886, proved conclusively that the shocks, (which occurred only in emergency stops), were due solely to the fact that the interval of time was too long between the application of the brakes on the successive cars. After this test was over, Mr. Westinghouse set himself at work to see if he could shorten such interval without the aid of electricity. He reverted to the principle of providing an *additional* and special valve for the purpose of venting the train-pipe under each car to the atmosphere, as set forth in his patent of July 22, 1879, No. 217,838; but modified the embodiment there shown by providing that said valve should be operated by the piston of the triple-valve of patent No. 220,556 in the act of making its final or complete traverse for an emergency stop (p. 124). Subsequently, he further improved this quick-action device by providing that the *added special valve* should vent the air into a *check-valved by-passage* leading directly from the train-pipe to the brake-cylinder, so as to save and utilize the locally vented air instead of discharging it to the atmosphere. And, on March 29, 1887, he patented this improvement in the patent here in suit, No. 360,070.

THE DEVICE OF THE PATENT IN SUIT.

In this device Mr. Westinghouse took the old plain triple-valve of patent 220,556 as the foundation of the structure. The piston of that valve already had a *preliminary* or *partial* traverse for graduating purposes, and a *final* or *further* traverse for emergency stops. (See testy. of H. H. Westinghouse, p. 307, Ans. 488.)*

To this old structure, he *added* his new auxiliary-valve and its check-valved *by-passage*, and arranged them so that the new auxiliary-valve, designed only for emergency-stop purposes, should be brought into action by the *old further* or emergency traverse of the piston. The change thus made is clearly illustrated in the three cuts opposite this page, where the members added to the device of patent 220,556 to form the improved device of patent 360,070, are shown in *red*, the first of the three cuts representing the old triple-valve of patent 220,556, the second cut representing the entire new combination with the auxiliary-valve 41 seated and closing the by-passage 42, 43, 46, and the third cut representing the entire new combination with the auxiliary-valve 41 unseated, as in the act of making an emergency stop. The course of the air from the auxiliary-reservoir to the brake-cylinder, passing through the triple-valve, is shown by a yellow line, and the course of the air from the train-pipe, passing through the auxiliary-valve device to the brake-cylinder, is shown by a blue line. It will be noted that the course of the train-pipe air (blue) is wholly *independent* of the triple-valves. It is obvious at a glance that if the auxiliary-valve 41 were removed and the passage 42, 43, 46 plugged or closed, the structure of 360,070 would simply be reduced back to the old device of patent 220,556.

In graduating or making a service stop, the new structure operated precisely like the old—the piston, in such cases, not moving back far enough to unseat the auxiliary valve 41; but in making an emergency stop, the piston, executing its full

*“ In the construction, as shown in patent 220,556, the opening of the larger port from the auxiliary-reservoir to the brake cylinder under certain circumstances (emergency) requires that the traverse of the triple-valve piston and its valves shall be *considerably greater* than is required to make the less rapid (or graduated) application of the brakes, and this requirement of *further traverse* increases the length of all the principal portions of this structure fully twenty-five per cent.”

Testy. of H. H. WESTINGHOUSE, p. 307, Ans. 488.

BLEED. THROUGH POOR COPY

traverse, unseated the auxiliary valve and vented the train-pipe air directly through the by-passage into the brake-cylinder, thereby causing a more sudden reduction of pressure in the train-pipe than if said air had to travel to the locomotive, and hence, speeding the application of the brakes on the next succeeding car. To prevent the heavier pressure of the auxiliary-reservoir from entering the brake-cylinder too quickly, and by its back-pressure checking the vent from the train-pipe, Mr. Westinghouse restricted the main port of the main valve 14 by somewhat elongating the main valve and cutting a small port 35 through it to register with the passage 33 when making an emergency stop, instead of using a shorter main valve arranged to entirely uncover the passage C, as in patent 220,556.

In making an emergency stop with this apparatus, the unseating of the new auxiliary-valve 41 would suddenly vent from the train-pipe to brake-cylinder a pressure of about 25 pounds to the square inch (see specification of patent 360,070, p. 467, near bottom of page); and the air flowing from the auxiliary-reservoir to the brake-cylinder through the passage 35-33 (as at C in the old triple-valve, but somewhat more slowly by reason of the restricted main port 35) would then gradually raise the 25 pounds in the brake-cylinder to about 55 pounds.

THE NEW APPARATUS A PRACTICAL FAILURE.

With the apparatus of patent 360,070, which we have just described, Mr. Westinghouse appeared at the Master Car Builders' second Burlington test, commencing May 13, 1887, he having also appeared at the first test, in 1886, with a plain triple-valve; *but the apparatus of 360,070 was a complete failure, so far as concerns the prevention of shocks*, the sole object of its existence. It reduced the time of applying the brakes on the rear car to less than six seconds, but it did not shorten the time enough; and the result was, that *the shocks were increased instead of being diminished*, the slidometer showing a "shock" of 103 inches as compared with the maximum of 49 inches shown by the old automatic triple-valve at the first tests of July, 1886 (p. 126.)

"In fact," says *Mr. H. H. Westinghouse*, when testifying as to the shock produced by the device of patent in

suit (p. 126), "they were so severe that it was not *deemed*
 "prudent to use the brake in emergency applications
 "without the use of the electrical valves heretofore
 "described. When these were used, the desired coinci-
 "dence of operation was secured and stops were made
 "without perceptible shock."

The Committee reported (p. 128) that:

"The brilliancy of the record was completely spoiled
 "by the fearful shock given at the rear end," and that
 " * * * in the electrical stops, the slidometer never
 "moved, and this with the same cars, the same leverages,
 "and the same pressures, the only difference being the
 "time of application."

Mr. H. H. Westinghouse testifies (p. 130) that:

"The conclusion of the 1887 trials (with the device of
 "patent 360,070), instead of furnishing to the railroads
 "the desired information upon which to take prompt and
 "reasonable action, served to show that much yet
 "remained to be done before it could be safe to make a
 "practical move in a matter of so great importance.
 "These sentiments were clearly expressed in the com-
 "mittee's conclusion from the 1887 trials."

The problem was still unsolved; and immediately after the close of the tests at Burlington in May, 1887, Mr. Westinghouse again went to work to effect its solution, which result he finally accomplished in the fall of 1887, *six months after the failure of the device of the patent here in suit*, and by means of devices patented by him January 24, 1888, No. 376,837, which reduced the time of applying the brakes on the rear car down to two seconds.

THE SUCCESSFUL DEVICE OF PATENT No. 376,837.

(NOT HERE IN SUIT.)

After the failure of the device of patent No. 360,070, in the Spring of 1887, the invention of the successful device of patent 376,837 was by no means obvious or easy, but required intense study and great inventive ability. *Mr. H. H. Westinghouse* (p. 131) testifies as follows :

"In obtaining this maximum result" (that is, evolving the successful device of patent 376,837) "the period of time "from the middle of May, immediately after the completion of the 1887 trials, until the first of October was "consumed. As may be imagined, the final result was "not obtained at once, but by repeated steps which required the complete refitting of the 50-car train not less "than three times. All the resources and employes that "could be used were kept at work day and night without "cessation, and the materials for trial, each time involving more than a car-load, was conveyed from Pittsburg "to Burlington by express, so that no time might be lost. "When, finally, in the latter part of September, 1887, the "last brake was applied in two seconds from the time of "the movement of the valve by the engineer, the source "of objectionable criticism that had heretofore existed "against the use of compressed air, unaided by electricity, "in the operation of power brakes upon long freight "trains, disappeared, and the "quick-action automatic" "brake, *as then constructed and organized*" (see patent 376,837, not in suit), "became, and has since been, the "standard power-brake apparatus for both freight and "passenger trains."

It will conduce to a better understanding of the character and limitations of the invention of patent 360,070, if we now examine the apparatus of patent No. 376,837 and observe the difference between the two devices.

In 376,837, the auxiliary-valve 41 is no longer immediately adjoining the piston so as to be actuated directly by the impact of the triple-valve piston, as in 360,070, but in the second patent is arranged opposite the main-valve chamber and actuated by a *supplementary piston*, 63, which supplementary piston, in its turn, is actuated by auxiliary-reservoir air admitted against its inner end by the extreme movement of the main-valve 14, in the act of making an emergency stop. The device is represented in the cut on the opposite page, in which the "auxiliary valve" and by-passage, the *additional members* of patent 360,070, are shown *in red*, and the still further additional members of a "supplemental piston" and piston-chamber, of patent 376,837, are shown *in brown*. The triple-valve is the *same* as that of patent No. 220,556, with an extra port uncovered by the main-valve to admit air from the auxiliary-reservoir against the supplementary piston 63, which actuates the "auxiliary-valve."

It therefore clearly appears that the points which are common to both patents—360,070 and 376,837—are as follows:

- 1, The old triple-valve parts of patent 220,556, which has expired;
- 2, A special by-passage leading directly from the train-pipe to the brake-cylinder;
- 3, A special "auxiliary-valve" to control said by-passage.

It also appears that the patent 376,837 differs from patent 360,070 by the former having:

- 1, An additional piston-chamber at the side of the triple-valve piston-chamber;
- 2, A "supplemental piston" arranged to be actuated by auxiliary-reservoir air;
- 3, And by actuating the "auxiliary-valve" by the "supplemental piston" instead of by the triple-valve piston, as in 360,070.

In other words, the invention of patent 376,837 consisted in combining the old triple-valve of patent 220,556, the new

Successful Device of the Later Patent, No. 376,837 of 1888.

The Triple Valve of this device is substantially the same as Patent 220,556, and 360,070. This device differs from Patent 360,070 here in suit and which was unsuccessful that the "Auxiliary Valve 41" is actuated by a supplemental piston instead of being actuated directly by the Triple Valve Piston.

The supplemental piston and its chamber are colored brown, and the "Auxiliary Valve 41," and by-passage of 360,070 are colored red.

auxiliary-valve and by-passage of patent 360,070, with a *supplemental piston* and piston-chamber as a motor apparatus for actuating said auxiliary-valve, thereby relieving the piston of the triple-valve from this *extra* work, and thus, as stated by Judge Townsend, in discussing these *two* patents in the New York air-brake suits, "his *later* 376,837 patent was the *bridge*, and not a step, which carried railroad car-builders from FAILURE to success."—(63 Fed. Rep., 969.)

WHAT IS 360,070 ENTITLED TO COVER?

In view of the foregoing facts, the question is, what invention was patent 360,070 entitled to cover? We answer:

It was *not* entitled to broadly cover the prevention of "shock" in long trains, because it did not prevent shock, for the test at Burlington showed it greatly increased it. It was *not* entitled to cover the local venting of the train-pipe at each car in order to quicken the serial or successive applications of the brakes along the train; because that principle had been made public in the prior patent of Mr. Westinghouse, No. 217,838, dated July 22, 1879. It was *not* entitled to cover the utilization of the "extreme traverse" of the triple-valve piston for the purpose of making emergency stops; because that had commonly been done for many years in patent 220,556 and others.

It *was* entitled, however, to cover a mechanical device, namely, the auxiliary-valve 41 governing a special by-passage leading directly from the train-pipe to the brake-cylinder—a device which, although of no utility as arranged in patent 360,070, became afterward exceedingly useful when further combined with the supplementary piston, of patent 376,837. In other words, patent 360,070, while not solving the problem of quick-action, furnished for its subsequent solution by Mr. Westinghouse an important *factor*, consisting of the auxiliary-valve and its by-passage, arranged to be put into action by the "extreme traverse" of the triple-valve piston. This patent, 360,070, did not itself accomplish the desired result; but it furnished an *element* for the subsequent combination by which Mr. Westinghouse finally achieved that result. *It should be construed, therefore, as a patent for that element or factor broadly, and for nothing more.*

LEGAL CONSTRUCTION OF PATENT 360,070.

If, now, we carefully examine patent 360,070, we shall find that it covers that element, the auxiliary-valve and by-passage in combination with the old automatic brake elements.

The specification commences (page 782), with a statement of the invention, and then describes, in a general way, the old plain triple-valve—this part of the description running to the top of page 784. It then says, on page 784 (the italics being ours):

“So far as the performance of its preliminary function
“in ordinary braking is concerned—that is to say, effect-
“ing the closure of communication between the main
“air-pipe and the auxiliary-reservoir and the opening of
“communication between the auxiliary-reservoir and the
“brake-cylinder in applying the brakes, and the reverse
“operation in releasing the brakes—the triple valve 10
“accords substantially with that set forth in letters patent
“of the United States No. 220,556 granted and issued to me
“October 14, 1879, and is NOT, THEREFORE, *saving as to*
“*the structural features by which it performs the further*
“*function of effecting the direct admission of air from*
“*the main air-pipe to the brake-cylinder*, as presently to
“be described, CLAIMED as of my present invention.
“Certain of its elements devised and employed by me
“prior thereto will, however, be herein specified in order
“to render its construction and operative relation to other
“members of the brake mechanism fully intelligible.”

This is a plain and emphatic direction, by Mr. Westinghouse himself, as to *how* the claims are to be construed. They are to be construed as covering only the “*structural features*” by which the direct admission of air from the train-pipe to the brake-cylinder is effected.

The specification then proceeds, to the bottom of p. 785, to describe in greater detail the devices which correspond to those of the old plain triple-valve, including the graduating valve 29 and the restricted port 35 through the main valve 14; after which, not content with the emphatic statement above quoted, it again says:

"So far as hereinbefore described, the triple-valve accords in all substantial particulars with and is adapted to operate similarly to those of my letters patent Nos. 168,359, 172,064, and 220,556, and, in order that it may perform the further functions requisite in the practice of my present invention, it is provided with *certain additional members*, which will now be described."

In the next twenty-two lines following the paragraph last quoted, the specification describes the new auxiliary-valve 41 and its check-valved by-passage, 42, 43, 46, 47, 48, as the said "additional members" by which the new functions of the structure are performed.

Following this is a long description of the operation of the structure, a disclaimer, and the claims.

We have already seen that the *invention* was limited to the *additional* element or factor, the new auxiliary-valve 41 and its by-passage, for effecting the direct admission of air from the train-pipe to the brake-cylinder; we now see that the *patent* limits itself to this new element or factor, both by declaring that it is this *new* factor which produces the desired result, all else being old, including the two traverses of the triple-valve piston, and by directing that the claims are to be construed as for these "*structural features*" by which this result is accomplished.

Whatever claims the patent may contain, therefore, must be construed in the light of these statements found in the patent itself. The stream can rise no higher than the source—the patent can claim nothing beyond the invention.

The claims in suit are as follows :

"1. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, a triple-valve, and an auxiliary-valve device, actuated by the piston of the triple-valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake-cylinder, substantially as set forth.

"2. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, and a

"triple-valve having a piston whose preliminary traverse
 "admits air from the auxiliary reservoir to the brake-
 "cylinder, and which, by a further traverse, admits air
 "directly from the main air-pipe to the brake-cylinder,
 "substantially as set forth.

* * * * *

"4. The combination, in a triple-valve device, of a
 "case or chest, a piston fixed upon a stem and working in
 "a chamber therein, a valve moving with the piston-stem
 "and governing ports and passages in the case leading to
 "connections with an auxiliary-reservoir and a brake-
 "cylinder and to the atmosphere, respectively, and
 "an auxiliary-valve actuated by the piston-stem and con-
 "trolling communication between passages leading to
 "connections with the main air-pipe and with the brake-
 "cylinder, respectively, substantially as set forth."

It will be observed that *these three claims are for one and the same invention*, being merely different expressions thereof.

There can be no question as to the proper legal construction of claims 1 and 4, both of which are, in terms, expressly limited to a combination containing the new *auxiliary-valve*, and also containing (in claim 4 expressly, and in claim 1 by necessary implication) the by-passage governed by said valve.

The Defendants, as we shall hereinafter show, *do not employ an auxiliary-valve or by-passage, nor any mechanical equivalent thereof, for admitting train-pipe air to the brake-cylinder*. Judge Morris, of the Circuit Court, so held, and the Circuit Court of Appeals affirmed his ruling on this point.

The Complainants, however, contend that *claim 2* is to be broadly construed as covering any triple-valve in which the old *further traverse* of the piston is retained in making an emergency stop where the train-pipe air is admitted directly to the brake-cylinder, whether by means of the auxiliary-valve and by-passage, or their mechanical equivalent, or by any other means whatsoever. On this question Judge Morris held, in substance, that claim 2 is entitled to cover not only mechanical, but *functional* equivalents, and that, therefore, the Defendants' apparatus, while not an infringement of claims 1 and 4 (because it does not contain the auxiliary-valve and by-passage, or their mechanical equivalents), falls within the scope of claim 2,

because it produces the same *result* by other means. The Circuit Court of Appeals strongly disaffirmed this conclusion, both as contrary to law and as evidently based by Judge Morris upon his erroneous belief that the patent in suit was the first to show a triple-valve piston having a partial traverse for graduation and a further or extreme traverse for emergency stops.

The whole controversy in the Supreme Court hangs upon the question whether the Circuit Court of Appeals was right in its conclusion upon this point, or whether Judge Morris was right.

That the Circuit Court of Appeals was right, appears conclusively, we submit, from the following facts:

1. The invention of patent No. 360,070 did *not* consist in giving the triple-valve piston a partial traverse for graduation and a "further traverse" for emergency stops; because automatic triple-valves for years prior to patent 360,070 contained and used that feature, as we have already shown, and as the Circuit Court of Appeals conclusively demonstrated in the paragraph commencing on p. 879 and ending on p. 880. Moreover, the specification of patent 360,070 makes no claim to any novelty in such feature, but asserts repeatedly that the triple-valve itself, apart from the auxiliary-valve 41 and its by-passage, "accords in all substantial particulars with, and is adapted to operate similarly to, those of my letters patent Nos. 168,359, 172,064 and 220,556" (p. 78), "and *is not*, therefore, saving as to the *structural features by which it performs the further function* of effecting the direct admission of air from the main air-pipe to the brake-cylinder, as presently to be described, *claimed* as of my present invention." (Page 784).

To assert any novelty, therefore, in the partial traverse and further traverse, is to assert not only what is not true in fact, (H. H. Westinghouse, p. 307, Aus. 488) but what is expressly denied to be true in the patent itself.

2. The patent also clearly and positively declares that the invention resides solely in the *addition* of the auxiliary-valve

41 and its by-passage, to the old well-known triple-valve. It resides in the "structural features" by which the old triple-valve "performs the further function of effecting the direct admission of air from the main air-pipe to the brake cylinder" (p. 784), and in the "*certain additional members*" by which the old triple-valve is enabled to "perform the further functions requisite in the practice of my present invention" (p. 786). Without these "structural features" or "additional members," the invention of Mr. Westinghouse is not present. The claims no matter how they may read, must, by legal construction, be limited to the *invention*—otherwise they would be invalid. So limited, they only cover combinations containing an auxiliary-valve 41 and its by-passage, or their mechanical equivalents; and are not infringed by the defendants.

3. In any event, the auxiliary-valve and its by-passage must be read into claim 2, in order to prevent the claim from being void as covering a mere *function or result* independently of the means for its accomplishment.* The claim refers to "a *piston* (the old piston) whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder." *The piston does no such thing.* Its function on the further traverse is to move the main-valve 14 and also *to move the auxiliary-valve 41*, and it is the latter, together with its by-passage, which "*admits air directly from the main air-pipe to the brake-cylinder.*" Without the auxiliary-valve 41, the *piston* is the same old piston which had been known, used, and patented, many years before the patent in suit, and a claim upon it in patent 360,070 would certainly be invalid. It is perfectly clear, therefore, that the auxiliary-valve 41 and its by-passage must be read into claim 2, in order to save the claim from being functional, to make it include the *necessary* elements for accomplishing the result, and to

* Whether they can properly be read into claim 2 involves a serious question of law, which is discussed by Mr. Church in another brief herewith filed. If they can *not*, the claim is clearly invalid; if they *can*, we do not infringe it. The object of the present brief is to discuss only the question of infringement, leaving the other question to Mr. Church's brief.

differentiate it from the old structure of patent 220,556, which employed the *same* piston having the *same two traverses*. The expression, "whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse admits air from the main air-pipe to the brake-cylinder," is simply the expression of a *result*; and that expression must be translated or interpreted into the mechanical means which produce the result, or else the claim must be held void. (*O'Reilly vs. Morse*, 15 How. 62, 119). So translated, this claim is not limited to less than what Mr. Westinghouse invented; but it does complete justice to him, fully covering everything which he added to the old triple-valve or which he described in his specification as new.

The claim must also be so translated as above, in order to give effect to its concluding words, "*substantially as set forth*." Mr. Westinghouse "set forth" no other means of producing the result, except the auxiliary-valve 41 and its by-passage. These words, therefore, become idle and meaningless except as a direction to the court to construe the auxiliary-valve and by-passage into the claim.

"Where the claim immediately follows the description
"of the invention, it may be construed in connection with
"the explanation contained in the specifications; and
"where it contains words referring back to the specifications,
"it cannot properly be construed in any other
"way."

Seymour vs. Osborne, 11 Wall., 547.

Miller vs. Eagle Mfg. Co., 151 U. S., 186, 202.

The Complainants are simply endeavoring to expand the second claim *beyond the invention* of Mr. Westinghouse and to make it include the accomplishment of the result by means which do not involve an auxiliary-valve and by-passage, but act upon an altogether different principle and by a totally different mode of operation.

4. Our position is strongly confirmed by certain admissions found in the Complainants' brief used in the Circuit Court of

Appeals for the Fourth Circuit. Thus, on page 40 of that brief, Complainants' counsel say :

" Thus it will be seen that this quick-action *attachment*, consisting of an *air-conduit or passage-way directly from the train-pipe connection to the brake-cylinder and a valve to control it*, such valve being itself under control of the triple-piston and so combined with the old automatic brake appliances that not interfering with the ordinary use of the latter it, the quick-action *attachment*, may be used as an *auxiliary* emergency device in the presence of great or serious danger—that *this*, the chief novelty and element of utility of the Westinghouse invention now in controversy, *is so made the subject matter of every claim in controversy as to give character and effect thereto*, and render the scope of the claim co-extensive with the invention."

Again, on page 31 of the same brief, the distinguished counsel for Complainant, after describing the old automatic triple-valve, refer to the new invention of patent 360,070 in the following words :

" Westinghouse added to and combined with this brake *another brake mechanism*, which, on account of its novel predominant characteristic or function, has given to the whole apparatus its own name of *quick-action* or *emergency brake*—both names being used. And he so combined these two mechanisms, 'the service' and 'the quick-action; that while, in fact, they constitute *two machines*, they are also included in a *single structure*, and are put into a co-acting or co-operating mechanical relation with each other, as will presently appear."

Counsel here mean that the old triple-valve was one machine, and the new auxiliary-valve 41, with its by-passage, was *another* "machine," and that the invention of patent 360,070 consisted in the combination of these two machines in one structure—a statement with which we entirely agree, and with which the

Circuit Court of Appeals, for the Fourth Circuit (p. 876), fully concurred. But it follows that machine No. 2 is a necessary element of the combination; that it must, by legal construction, be read into any claim which does not already express it, and that there can be no infringement where the defendant does not use it. These two admissions are conclusive as to the whole controversy over the legal construction of claim 2.

5. Our position is also conclusively confirmed by the exhibit, "*File - Wrapper and Contents*," of patent No. 360,070 (pp. 705 to 724).

It appears from this exhibit that the application for the Westinghouse patent was filed November 19, 1886; that the broad claim 1 and the more limited claim 2 were both rejected on the prior patent of Boyden, dated June 26, 1883, No. 280,285, and that on January 19, 1887, Mr. J. Snowden Bell, attorney for Mr. Westinghouse, wrote a letter to the Patent Office in which he erased the original broad claim 1 and substituted the present narrower claim 1, and made an argument in favor of the allowance of claim 2. In this argument he says (p. 718, near the bottom):

"It is to be understood that applicant (Westinghouse) *does not seek to broadly claim* a device for admitting "air directly from the main air-pipe to the brake-cylinder, "as the four-way cock long heretofore employed by him " (similar to the cock *K* of the Boyden patent) would be "a structure of such character. *When, however, the "triple-valve is provided with an auxiliary-valve operated "by its piston, which performs a new function addi- "tional to that of the triple-valve as previously employed, "it is believed that such combination is wholly novel."*

The above statement in the Patent Office file, on which claim 2 was reconsidered and allowed, undoubtedly operates, in law, to read the auxiliary-valve into claim 2; and it is a question whether it does not also operate to further limit the auxiliary-valve to one which is actuated by the direct impact

of the piston-stem, as described and shown in the patent. However the latter may be, it is certain that, in view of this statement of Westinghouse's Attorney, and of repeated decisions of this high tribunal as to the legal effect of such admissions made during the progress in the Patent Office of an application for letters patent, no court can rightly construe claim 2 as a broad claim unlimited to the "Auxiliary-Valve 41."

Moreover, claim 1 of the application was originally as follows:

"1. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder and *a triple-valve provided with a device* for admitting air directly from the main air-pipe to the brake-cylinder, substantially as set forth."

This broad claim (p. 714) was withdrawn (bottom of page 717), and the present claim 1 was substituted, limited in terms, to "an auxiliary-valve," "actuated by the piston of the triple-valve," and "independent of the main-valve thereof."

Again, the specification, as originally filed, contained the following broadening statement (top of p. 714):

"Further, while in the specific construction described and shown, the function of admitting air from the main-pipe is performed by a valve separate from that which effects the preliminary admission of reservoir-pressure to the cylinder, a modification in which the same office is performed by a valve integral with the main-valve and formed by an extension thereof, would be included in and embody the essential operative features of my invention."

This clause, also, was stricken out during the progress of the application through the Patent Office; so that the legal construction of the patent, as issued, is, that the auxiliary-valve must be separate from the main-valve and not formed by an extension thereof.

We see, then, *first*, that the invention of patent 360,070 was not, in and of itself, a solution of the problem of "quick-action" or of the prevention of shock in long trains, but merely furnished a device which, in combination with other devices subsequently invented, became a useful factor in Mr. Westinghouse's

later invention of patent 376,837; *second*, that whatever invention was contained in patent 360,070 consisted only in *adding* the auxiliary-valve 41 and its by-passage to the old triple-valve; *third*, that the specification of patent 360,070 described the invention as consisting merely in this addition, and directed the claims to be construed as limited thereto; *fourth*, that claim 2 must be held invalid unless the auxiliary-valve and by-passage are read into it; *fifth*, that Complainants' counsel admit that the auxiliary-valve and by-passage are "so made the subject matter of every claim in controversy as to give character and effect thereto"—the invention consisting practically in the combination of "*two machines*," one of which is the old triple-valve, and the other the new devices added to it by Mr. Westinghouse; and *sixth*, that while the application was pending in the Patent Office, Mr. Westinghouse, through his attorney, confined the invention to the new auxiliary-valve actuated by the piston of the triple-valve, and struck out all broad claims and broadening statements of the specification which might be in conflict with that theory.

It would seem that further argument on this point was unnecessary, but we cannot leave the subject without commending to the attention of the court the masterly reasoning of the Circuit Court of Appeals below, which fully sustains our position in every respect, nor without calling the attention of the court to the case of *The Westinghouse Air Brake Co. vs. The New York Air Brake Co.*, in the Southern District of New York (69 Fed. Rep., 71⁷; 16 C. C. A., 371, 373, 374, 376).

NEW YORK SUIT.

In that case Judge Lacombe (16 C. C. A. 371), referring to patents 360,070 and 376,837, said that they "disclosed the one, the emergency valve" (meaning auxiliary-valve 41), "the other the supplemental piston or special motor, which, so far as the art has now progressed, appear to be both essential to the structure of a successful quick-action air-brake."*

*The Boyden brake used by defendants here was not before Judge Lacombe, and he was ignorant of the fact that Boyden had solved the problem of quick action by *another plan* not involving the use of either an auxiliary-valve or a supplemental piston.

Then, on page 373, 16 C. C. A., referring to claim 1 of patent 360,070, Judge Lacombe said :

“The means for actuating the auxiliary-valve device “is stated in the claim to be ‘the piston of the triple-
“valve.’ And the way in which it acts, as shown in the
“patent, is by direct impingement upon the stem of the
“auxiliary-valve device.”

On page 374, same volume, referring to claim 2 of patent 360,070, he said :

“The discussion of the first claim *applies equally to*
“*this one.* In the first claim, actuation by the piston
“of the triple-valve was made an element. In this
“claim the inventor *more closely limits the mode of*
“*such actuation.* It is to be by a ‘further traverse’ of
“that ‘piston.’”

The Defendant in that case used the “auxiliary-valve” device, but actuated it *indirectly* by the piston of the triple-valve, and was found guilty of infringement. (See cut of New York Company's valve structure on opposite page. The auxiliary-valve device is shown in red.)

The Circuit Court of Appeals for the Second Circuit affirmed the decision of Judge Lacombe (16 C. C. A., 376), saying, with respect to patent 360,070, simply, that they “deem it unnecessary to add anything to the opinion of Judge Lacombe.”

It therefore clearly appears that Judge Lacombe, the Circuit Court of Appeals for the Second Circuit, and the Circuit Court of Appeals for the Fourth Circuit, are all in full accord with us on the proposition of law that the auxiliary-valve 41 must be read into claim 2 of patent 360,070. So construed, all the claims in suit are limited to the auxiliary-valve 41; and it only remains to show that the Defendants here do not use such valve or any mechanical equivalent thereof.

New York Brake Co.'s Valve.

Held to infringe by Judge Lacombe because it contained the "Auxiliary Valve" device (shown in red) of Patent 360,070.

The "Auxiliary Valve 41" of Patent 360,070 is shown in red, and the "Supplemental Piston" and chamber of Patent 376,837 shown in brown.

Defendants Triple Valve Structure.

With the Immovable Partition 9 inserted.

Fig. 1. Release Position.

Fig. 2. Quick-Action Position.

Fig. 2 shows the Defendants Triple Valve Structure in the quick-action position, and the Main Valve 22 in the act of admitting both Train Pipe and Auxiliary Reservoir airs to the Brake Cylinder.

The course of the Train Pipe Air is shown by a Blue line, and that of the Auxiliary Reservoir Air by a Red line. It will be noted that both airs commingle in the Triple Valve Chamber C, and together pass to the Brake Cylinder through the port opened by the Main Valve 22 (black), thereby not requiring an Auxiliary Valve to admit the Train Pipe Air.

THE DEFENDANTS' QUICK-ACTION AIR-BRAKE.

The Defendants are charged with infringing claims 1, 2 and 4 of patent 360,070, by making, selling and using a brake apparatus like that patented to George A. Boyden, August 16, 1892, Nos. 481,134 and 481,135 (pages 797 and 809), the respective applications for which patents were filed in the Patent Office, the first one September 30, 1889, before this suit was brought, and the second one March 6, 1891.

The Defendants' device is illustrated in the cuts printed on the opposite page.

In this device no auxiliary valve or by-passage is employed; but the quick-action result is effected simply by properly proportioning the ports and passages of the old plain triple-valve and using a fixed partition (9) to divide the piston chamber D from main-valve chamber C. With the ports and passages of the old triple-valve properly proportioned, the partition 9 is the element which produces "quick action" in the Boyden structure. The partition is not a valve nor the mechanical equivalent of a valve, but is merely a metal ring screwed immovably into the triple-valve casing, and serving to divide the piston-chamber from the main-valve chamber. It was a new element never before found in triple-valves, and it introduced a new principle and mode of operation totally different from anything ever invented by Mr. Westinghouse or any other inventor. It involved a new and brilliant discovery and invention on the part of Mr. Boyden, of masterly ingenuity and originality.

The effect of the partition 9 is to make the main-valve 22 (black) of the triple-valve admit the train-pipe air to the brake-cylinder at the same time it admits the auxiliary-reservoir air thereto. The simultaneous admission of the two airs through the port of the main-valve 22 is shown by colored lines in Fig. 2, on opposite page.

In embodying this new principle, Mr. Boyden adopted the general form of triple-valve shown in the expired Westinghouse patent, No. 141,685, dated August 12, 1873 (p. 736) in which the main-valve 22 is of the poppet form, and a separate valve 17 controlled by a rod sliding through the main valve is employed for releasing the brakes. For charging the auxiliary-reservoir, he adopted, from the expired Westinghouse patent No. 144,006,

dated October 28, 1873, (p. 740), a check-valved feed passage through the triple-valve piston (Hogan, p. 284, Ans. 413); but arranged the feed passage and its check-valve 26, in a tubular extension F, of the piston, and substantially in the form shown in Fig. 3 of his own patent, No. 280,285, dated June 26, 1883 (p. 776, and see cuts opposite to p. 498). He also provided a sensitive graduating valve, similar in results to the graduating valve e¹ of the now expired Westinghouse Patent, No. 220,556, dated October 14, 1879, by so arranging a small passage 40 in the sliding-stem which actuates the release-valve that said passage will be opened and closed by the sliding of said stem through the main-valve 22. As thus constructed, the triple-valve operates in all respects substantially the same as that of patent 220,556, and like the latter, is incapable of "quick-action."

The two cuts on opposite page represent respectively the old plain triple-valve patent No. 220,556 and Defendants' structure *without* the partition 9. The corresponding valves in both cuts are colored alike in order that they may be readily located in the following analogy :

ANALOGY.	Defendants' Structure.	Patent No. 220,556.
In both there is a feeding-in-valve (<i>blue</i>) to charge the auxiliary-reservoir— designated.....	26	a
In both there is a graduating-valve (<i>yellow</i>) which is opened by the "preliminary traverse" of the piston to admit auxiliary-reservoir air to the brake-cylinder—designated.....	40	e ¹
In both there is a main valve (<i>black</i>) which is opened by the "further traverse" of the piston to also admit auxiliary-reservoir air to the brake-cylinder—designated.....	22	H
In both there is a release-valve (<i>green</i>) which discharges air from the brake-cylinder to the atmosphere—designated.....	17	s

Both of these devices are plain "triple-valves" incapable of

Triple Valve of Patent 220,556 of 1879.

Defendants Triple Valve Structure

With Partition 9 Removed, and therefore incapable of Quick-Action

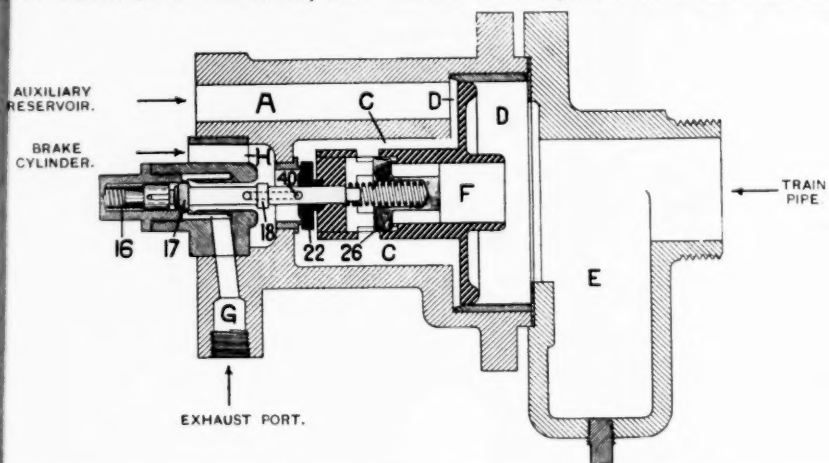

In both structures there are four valves—Feeding-in Valve, Blue; Graduating Valve, Yellow; Release Valve, Green, and Main Valve, Black. The valves all functionate as Triple Valves, and it follows that if said valves are "Triple Valves" in 220,556, they are also Triple Valves in defendants structure. The piston in both has a "preliminary traverse" and "further traverse," the two traverses being old, and used since 1873.

Triple Valve of Patent 220,556 of 1879.

Defendants Triple Valve Structure

With Partition 9 Removed, and therefore incapable of Quick-Action

In both structures there are four valves—Feeding-in Valve, Blue; Graduating Valve, Yellow; Release Valve, Green, and Main Valve, Black. The valves all functionate as Triple Valves, and it follows that if said valves are "Triple Valves" in 220,556, they are also Triple Valves in defendants structure. The piston in both has a "preliminary traverse" and a "further traverse," the two traverses being old, and used since 1873.

"quick-action," the operation of 220,556 being described on pp. 5, 6 and 7 of this brief. They each produce exactly the same result, and each of the four valves in the two devices perform the same function. If the said valves in 220,556 are "triple-valves," it follows that the corresponding valves in Defendants' structure are *also* triple-valves.

Each structure has a piston with a "preliminary traverse" to open the graduating-valve (yellow) to partially or slowly apply the brakes, and a "further traverse" to open the main-valve (black) for a quick or an emergency application of the brakes. Both these devices are old and public property. The Defendants' device, as here shown, does *not* contain the "partition 9."

Starting from this point, Mr. Boyden, with the *poppet* form of the old triple-valve 141,685, before described, and Mr. Westinghouse, with the triple-valve of patent 220,556, both inventors sought to solve the problem of "quick action," but they proceeded in very different directions, and by respectively calling to their aid means which are so unlike as to be absolutely incapable of comparison with each other, and of which the Circuit Court of Appeals, in its opinion (p. 880), said:

*"They seem to us to differ as widely from each other
"as two devices for accomplishing the same result can
"well differ."*

Mr. Boyden conceived the idea of developing the *latent* capabilities of the valves of the old triple-valve by *creating therein special differential pressures*, so that *these same valves* will have the *new power* of admitting train-pipe air to the brake-cylinder for emergency applications of the brakes. Mr. Westinghouse had the idea of retaining the old triple-valves to do no more than their old functions, and in order to obtain the new object he conceived the plan of *adding* a new auxiliary-valve 41 and its by-passage to the old triple-valve of patent 220,556, thereby, as Complainants' counsel admit, adding a *new "machine"* to the old one, and combining both together in one structure; and he produced, *not* "quick-action," but an "auxiliary valve" device, which, at a later period, became a *factor* of paramount importance to him in the production of quick action.

Mr. Boyden added no new valve or by-passage—no new *machine*—but he simply connected his auxiliary-reservoir to

the inner end of the *piston-chamber* by means of a capacious passage *A*, and divided said piston-chamber from the main valve chamber by a partition 9 having a passage *B* the capacity of which was less than that of the passage *A*, and intermediate in size between that of the graduating passage 40 and that of the port covered by the main valve 22—and he thereby produced a perfect quick-action triple-valve.

The operation of the Boyden device was as follows :

Recharging the auxiliary reservoir and releasing the brakes.—The engineer accomplishes these functions, as in all automatic air-brakes, by increasing the pressure in the train-pipe. This forces the triple-valve piston to the inner end of its traverse (as shown in the upper cut opposite p. 35), unseating the release-valve 17 and releasing the brakes, seating the main valve 22, and closing the graduating port 40. The pressure of train-pipe air now lifts the feed-valve 26 (as in Westinghouse patent No. 144,006 and Boyden patent No. 280,285), and flows into the main-valve chamber *C*, whence it passes back through the restricted opening *B* into the space between partition 9 and the triple-valve piston, and thence flows through passage *A* to the auxiliary-reservoir. When the pressure in the train-pipe reaches its maximum of 70 pounds and ceases to further increase, the check-valve 26 becomes seated by its spring, thereby preventing any reflux of air from the auxiliary-reservoir to the train-pipe; and the pressures equalize in the auxiliary-reservoir, the main-valve chamber, and the passages connecting them. The apparatus is now in its normal running condition.

Graduating.—The engineer effects this function, as in all automatic air-brakes, by discharging about 10 pounds of air-pressure from the train-pipe. The superior pressure of the auxiliary-reservoir now moves the triple-valve piston through its partial traverse, thereby causing the release-valve 17 to seat and close communication between the brake-cylinder and the atmosphere. At the same time, the piston, by said partial traverse, draws its own stem back through the main-valve 22 far enough to open the graduating port 40 and allow auxiliary-reservoir air to flow slowly into the brake-cylinder and set the brakes with a light pressure. The auxiliary-reservoir pressure in the valve chamber *C* meanwhile holds the main-valve 22 so

firmly seated that when the collar 18 on the piston stem strikes the main-valve it does not unseat the latter, but merely arrests the movement of the piston, thereby limiting the latter to its partial traverse. The passage *B*, being larger than the graduating port 40, supplies more air than can escape through the latter, and therefore maintains an equality of pressure between the auxiliary-reservoir and the main-valve chamber. This pressure slowly decreases by the vent through port 40 into the brake-cylinder, and when it becomes slightly lower than the train-pipe pressure (now 60 pounds), the latter moves the piston back far enough to close port 40. The piston cannot move far enough, however to open the release port, because, in attempting to do so it would necessarily have to compress, and thereby increase the resistance of, the auxiliary-reservoir air (which is now confined without means of escape), and also because of its own friction. If the engineer desires to increase the pressure of his brakes, he discharges a few more pounds of air from the train-pipe, and the operation above described is repeated; and so on, till he reaches any degree of brake-pressure required for slacking the speed of the train or bringing it to a "service-stop," as the case may be. He releases the brakes and recharges the auxiliary-reservoir by increasing the train-pipe pressure to its normal 70 pounds.

Making an Emergency Stop.—When the engineer discovers danger closely impending, he instantly throws his governing-valve wide open. This suddenly vents a larger amount of air (15 or 25 pounds) from the train-pipe. The auxiliary-reservoir pressure on the first car is now so greatly in excess of the train-pipe pressure that the preponderance instantly forces the triple-valve piston to the extreme outward limit of its traverse, thereby causing the main-valve 22 to unseat and fully open its port, so that auxiliary-reservoir air can flow rapidly and freely to the brake-cylinder to set the brakes with maximum quickness and force.

Up to this point every operation and result have been precisely the same as those of the old automatic air-brakes in use prior to the date of the patent in suit—1887. But now a new action takes place, peculiar to the new Boyden brake, and constituting its new principle and mode of operation, The port of the main-valve 22 is so much larger than the passage B that the pressure in the main-valve chamber C is instantly emptied into the brake-cylinder, and, as the passage B cannot supply air so fast as the main-valve port can exhaust it, the pressure in the main-valve chamber suddenly drops to about 5 pounds. Meanwhile the passage A, leading from the auxiliary-reservoir to the inner end of the piston-chamber, is so much larger than the passage B, leading from the piston-chamber to the main-valve chamber, that full reservoir pressure is maintained in the piston-chamber between the partition 9 and the inner side of the piston, thereby holding the piston back firmly at its extreme traverse. But the feed-valve 26 (blue) is now exposed on the one side to a train-pipe pressure of about 55 pounds, and on the other side to a main-valve-chamber pressure of only about 5 pounds, and therefore valve 26 is instantly forced open by the greater train-pipe pressure, which then vents freely through the said feed-valve port into the main-valve chamber C, where it commingles with the auxiliary-reservoir air passing through said chamber, and both airs pass together through the port opened by the main-valve 22 to the brake-cylinder. The whole operation is substantially instantaneous, and the result is that the train-pipe is freely vented at each car, the time of serially or successively applying the brakes of the several cars from one end of the train to the other is reduced to a minimum, and the train is quickly stopped without shock—a result which Mr. Westinghouse did not attain with the device of patent 360,070, nor did he attain it until he had invented his later apparatus of patent 376,837 not here in suit.

When the Court arrives at a clear understanding of the structure and "mode of operation" of the Boyden brake, it will see at once that, in the Boyden device, the partition 9 is the controlling element which produces "quick action." When this partition is present, the device operates as a quick-action air-brake; but remove the partition, and the device then operates

Defendants Triple Valve Structure

With Partition 9 Removed and Incapable of Quick-Action, Operating only as a Plain Triple Valve.

Defendants Triple Valve Structure

With Partition 9 in its Place and Capable of Quick-Action.

In the upper cut the structure operates as a plain Triple Valve, the Main Valve 22 admitting only Auxiliary Reservoir Air to the Brake Cylinder as shown by the Red line, but in the lower cut the structure operates as a Quick-Action Valve. The Main Valve 22 admitting both Auxiliary Reservoir and Train Pipe Air to the Brake Cylinder as shown by the Red and Blue lines.

This great transformation in the operation being due to inserting the partition 9. With the Defendants Structure is a perfect quick-action device without employing any

only as an old triple-valve—precisely like the triple-valve of patent 220,556. (See test'y. of H. H. Westinghouse, p. 336, ans. 601, pp. 345, 346, ans. 647, 648).*

The reason of this is as follows (see cuts on opposite page):

The passage *A* is equal to, or larger than, the port of the main valve 22, and, in the *absence of partition 9* (see Fig. 1), can supply auxiliary-reservoir air to the main-valve chamber *C* as fast as, or faster than, such air can vent from said chamber through the main-valve port to the brake-cylinder. Hence, in the absence of the partition 9, no sudden reduction of pressure in the main-valve chamber *C* is effected by the unseating of valve 22. The result is, that under such condition, the feed-valve 26 cannot be opened, and no train-pipe air can possibly pass into the main-valve chamber. Therefore, only auxiliary-reservoir air is admitted to the brake-cylinder, its course being shown by a red line.

But with the partition 9 in place (see Fig. 2), all this is changed. The opening of the main valve 22 suddenly reduces the pressure of the main-valve chamber *C* to about five pounds; this is due to the partition 9 preventing the auxiliary-reservoir air from freely entering the chamber *C*; the train-pipe air at 55 pounds will instantly pass into the chamber *C* through the feeding-in-valve 26, and thence to the brake-cylinder through the port opened by the main-valve 22 simultaneously with the passage of the auxiliary-reservoir air, thereby making the main-valve perform the two functions. The course of the train-pipe air is shown by a blue line, and that of the auxiliary-reservoir by a red line.

The operation is absolutely certain and reliable; and the invention of Mr. Boyden, by which it is effected, is entitled to rank as a scientific discovery of high order—the discovery that the old-fashioned triple-valve can be operated, simply by *differential pressures*, to produce the important quick-action result which Mr. Westinghouse supposed could be produced only by combining it with *a new machine for that specific purpose*, consisting in a new “auxiliary-valve” actuated by the piston of the triple-valve and controlling an additional by-passage leading from the train-pipe to the brake-cylinder.

*If the Court will permit, we will, with a full-size brake apparatus, operated by air-pressure, give an ocular demonstration of these facts at the hearing.

The Boyden principle is not confined to triple-valves having the main-valve and the release-valve of the "poppet" form, and therefore necessarily separate from each other, but is equally applicable to all other forms of triple valve. If we remove from the Boyden device the poppet main-valve 22 and the release-valve 17, and substitute therefor a slide-valve, exactly as in patent 220,556, with the graduating-valve shown in the latter patent, the result is just the same as with the new Boyden triple-valve above described. The Defendants manufacture triple-valves embodying the same invention in three forms, among which is the slide-valve form, patents for which were all granted on the same day—August 16, 1892, pp. 797-809-817.

THE COMPLAINANTS' ARGUMENT AND THE ANSWER THERETO.

The Complainants' argument is, that the sensitive valve 40 of the Boyden device is the main-valve; and that the valve 22 is only an auxiliary-valve, corresponding to the auxiliary valve 41 of patent 360,070, because it unseats only during the further traverse of the triple-valve piston in making an emergency stop, is unseated by said piston, and, when unseated, admits train-pipe air to the brake-cylinder directly (that is, without said air first passing to the auxiliary-reservoir).

The argument is specious, sounding in words rather than facts; and, when considered with reference to the actual operations of the two mechanical structures under comparison, it is not even plausible on its face. It did not deceive Judge Morris, who said (p. 844):

"In the Boyden mechanism, which is alleged in this case to infringe, I have not been able to satisfy myself

“that Boyden makes use of an “auxiliary-valve” in the
 “sense in which that term is employed in the specifica-
 “tion and in some of the claims of the patent No. 360,070
 “now in suit. * * * * * (p. 845), “and
 “the defendants’ valve 22 must be considered to be the
 “main-valve, and that in Defendants’ mechanism he has
 “been able, *by an ingenious arrangement restricting the*
 “*admission of auxiliary-reservoir air to the triple-valve*
 “*chamber*, to cause the main valve to do *both* main-valve
 “work, when needed, and to do quick-action work, when
 “needed.”

The Circuit Court of Appeals unanswerably refutes the Com-
 plainants’ argument saying (p. 881):

“Boyden’s (22) is not an auxiliary-valve; it is mechan-
 “ically the original main-valve of the original triple-
 “valve, and it performs the service which is performed
 “by the main-valve of 220,556. It is not the mechanical
 “equivalent of valve four” (auxiliary-valve 41) “in the
 “attached apparatus of Westinghouse simply by reason
 “of its taking part in an emergency service in admitting
 “train-pipe air into the brake-cylinder. In the original
 “triple-valve it (the main-valve) performed no other
 “service than admitting auxiliary-reservoir air into the
 “brake-cylinder; in Boyden’s device it continues to
 “perform that service, and is made incidentally instru-
 “mental in allowing the passage of train-pipe air. The
 “performance incidentally of quick-action service does
 “not make it an auxiliary-valve. It is the *same* valve.
 “The incidental *service* is auxiliary, but *the valve itself*
 “*is the same* and unchanged. We think the Circuit
 “Court was correct in its view that the poppet-valve 22
 “of Boyden is the original main-valve of 220,556.”

In the Boyden device, when the *partition 9 is removed* and the triple-valve is therefore capable of acting only as an old-fashioned triple-valve, it cannot for a moment be contended that valve 22 acts otherwise than as the old main-valve (the slide valve) of patent 220,556 (called the "main-valve" in claim 1 of the latter patent), or that the sensitive valve 40 acts otherwise than as the old graduating valve *e*¹ of patent 220,556. In both devices (Boyden and 220,556) the *partial* traverse of the piston leaves the main-valve covering the main-port to the brake-cylinder, but causes the sensitive valve to open a passage *through the main-valve* and admit auxiliary-reservoir air slowly to the brake-cylinder for graduating purposes; while the *further* or extreme traverse causes the main-valve to uncover the main port and admit auxiliary-reservoir air more freely and quickly to the brake-cylinder for emergency purposes.

By now inserting the partition 9, *which converts the Boyden device to a quick-action triple-valve*, the actions, operations and results of the old plain triple-valve structure, as just described, are not changed, but continue still to be performed just as before. Hence, if the valve 22 was a main-valve before, it is a main-valve still. Neither the valve nor its function is changed by the insertion of the partition 9. Its old emergency function was to open the main port fully and admit auxiliary-reservoir air to the brake-cylinder—a function which it still performs in the same way, and under the same circumstances. On the other hand, both in the Boyden device and in patent 220,556, the sensitive graduating valve performs an office which is subordinate to that of the main-valve, its function being, in the language of claim 1 patent 220,556, "to close or open *a port through the main-valve* without necessarily moving the main valve." This office is useful only for graduation. The sensitive valve, in both structures, is substantially *functus officio* when making an emergency stop.

It is a conspicuous fact that the sensitive graduating-valve 40 of Defendants' device corresponds with THAT valve of the patent in suit which the specification terms "a graduating valve 29." (See patent, page 785, bottom of second paragraph.) Therefore the argument of Complainants' counsel, that Defendants' valve 40 corresponds with the "main-valve" of the Patent in suit, is erroneous and misleading, because in fact said valve 40 corresponds with that valve which the Patent states is the "graduating valve 29."

Complainants' arbitrary and false process of classifying the several valves in Defendants' structure—the valve 40 (or i, j, k) as "*main*," and the valve 22 as "*auxiliary*"—leaves no valve in said structure which is classed as the "sensitive graduating valve;" the Court will, therefore, see that the classification itself is specious and altogether erroneous.

There is one slight and immaterial difference between the main valve of Boyden and that of patent 220,556, incidental to the use of a poppet valve for the former and a slide-valve for the latter. A slide-valve, acting both as a release-valve and a main valve, as in patent 220,556, must, in applying the brakes, be first moved slightly to close release-port, before the graduating valve is permitted to vent air into the brake-cylinder; whereas, with a poppet valve, which necessitates a separate release-valve, the latter must first be moved to close the release port, and the former need not move at all during the graduating operation. When Boyden uses the slide form of main-valve, however, this incidental and merely formal difference entirely disappears.

COMPLAINANTS' AND DEFENDANTS' STRUCTURES COMPARED.

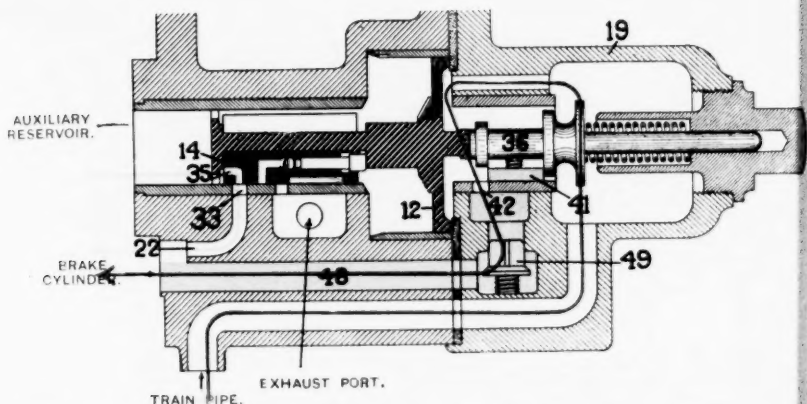

The two cuts on the opposite page represent structures, respectively, of the Complainants and Defendants. In those structures the parts forming the several valves are shown in colors, the corresponding valve in both structures having the same color. The feeding-in-valve is blue; the graduating-valve is yellow; the main-valve is solid black; the release-valve is green. In the Complainants' structure the "auxiliary-valve 41" and by-passage 46 are red.

In the Complainants' structure the piston has to move the graduating-valve (*yellow*), and then the main-valve (*black*) as in the old patent 220,556, and then to move a *third valve (red)* in performing the quick-action function: in the Defendants' structure the piston has to move the graduating-valve (*yellow*) and then the main-valve (*black*) as in the old patent 220,556, but it has to move *no (red or) third valve*—the quick-action being performed by the triple main-valve already moved, due to the partition 9 restricting the flow of auxiliary-reservoir air to the main-valve chamber C.

The course of the two airs (auxiliary-reservoir air and train-pipe air) are shown by colored lines in the cuts.

Fig. 1 shows the Complainants' structure with all the valves in the position they occupy for an "emergency" application of the brakes, wherein the air from the train-pipe (shown by a blue line) passes through a port uncovered by the auxiliary-valve 41, thence through a check valved by-passage (43, 46) to the brake-cylinder. The air from the auxiliary-reservoir (shown by a yellow line) passes through the main-valve port 35, of the triple-valve to the brake-cylinder. Thus, Complainants' structure retains the old main-valve to admit the auxiliary-reservoir air, but employs a new additional valve device to admit the train-pipe air.

Fig. 2 shows the Defendants' structure with all the valves in the position they occupy for an "emergency" application of the brakes wherein the air from the train-pipe (shown by a blue line) passes through the feeding-in-valve passage F into the

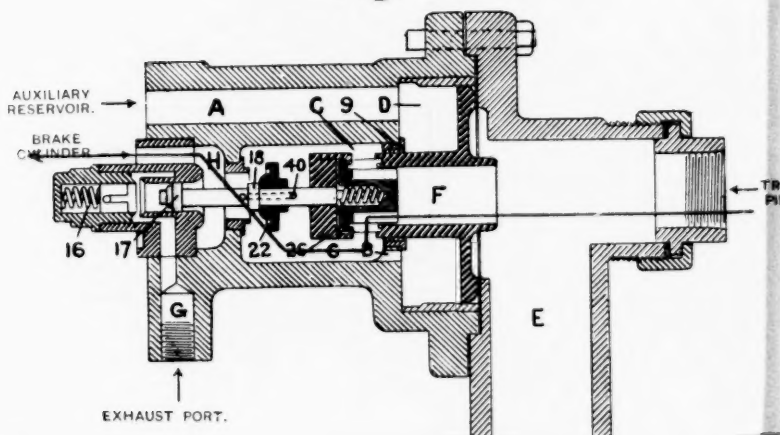

The course of the air from the Train Pipe to the Brake Cylinder is through the Auxiliary Valve and by-pass, colored Red, and is shown by a Blue line while the air passing from the Auxiliary Reservoir to the Brake Cylinder through Main Valve, Black, of the Triple Valve, is shown by a Yellow line. Thus in the complainants structure two machines are required to perform the two functions.

Defendants Structure.

With the Valves in the Quick-Action Position.

Fig. 2.

By a blue line, while the air passing from the Auxiliary Reservoir to the Brake Cylinder through the Main Valve of the Triple Valve, is shown by a Yellow line. Thus in the Defendants Structure only one machine is required to perform the two functions.

Complainants Structure of Patent 360,070

With the Valves in the Quick-Action Position.

Fig. 1.

The course of the air from the Train Pipe to the Brake Cylinder is through the port opened by the Auxiliary Valve and by-passage, colored Red, and is shown by a Blue line, while the air passing from the Auxiliary Reservoir to the Brake Cylinder through the Main Valve, Black, of the Triple Valve, is shown by a Yellow line. Thus in the complainants structure two machines are required to perform the two functions.

Defendants Structure.

With the Valves in the Quick-Action Position.

Fig. 2.

The course of the air from the Train Pipe to the Brake Cylinder is through the Trip Valve Chamber C and port opened by the Main Valve 22, Black, of the Triple Valve, and

FOLDOUTS TOO LARGE TO
BE FILMED

triple-valve chamber C, thence through the port uncovered by the main-valve 22 to the brake-cylinder. The air from the auxiliary-reservoir (shown by a yellow line) passes through the passage B, into said valve chamber C, then through the *same* port (uncovered by the main-valve 22) through which the air from the train-pipe is passing, to the brake cylinder, thereby retaining the old main-valve to admit the auxiliary-reservoir air and *causing the same valve* to admit the train-pipe air.

It will be seen from the foregoing that *one valve*, the old main-valve 22 of Defendants' triple-valve, admits *two airs* to the brake-cylinder when applying the brakes for quick applications, instead of *two valves*, the main-valve port 35 and auxiliary-valve 41 as used by Complainant, to admit the *two airs*.

The foregoing comparison of Complainants' and Defendants' devices shows that, while both obtain the same *result* of quick-action, the *means* and mode of operation by which they obtain that result are *totally dissimilar* having absolutely nothing in common. The quick-action *means* of the one is necessarily an auxiliary-valve device whereby train-pipe air may pass direct to the brake-cylinder independent of the triple-valves and "additional" to them, as Mr. Westinghouse correctly states in his patent, and as Mr. H. H. Westinghouse testified at the bottom of p. 124 of the transcript; the quick-action means of the other is a *mere modification* of the triple-valve structure *itself*, consisting of the immovable partition 9 and properly proportioning the original passages, whereby train-pipe air may pass direct to the brake-cylinder through the triple-valves.

It is therefore obvious that the Defendants' structure is totally destitute of the means described and claimed in the patent in suit to admit the train-pipe air to the brake-cylinder.

Mr. Boyden, in making up his triple-valve, used only the old triple-valve elements well known prior to 1886, to wit: The feed-valve of patents 144,006 and 280,285, the main-valve and release-valve of patent 141,685, and the graduating-valve of patent 220,556; and that his triple-valve structure comes squarely under the definition of "triple-valve" as given by Mr. Westinghouse in the specification of the patent in suit, where he says (p. 468):

"In using the terms 'triple-valve' and 'triple-valve device,' I refer to a valve device, *however specifically*

“constructed, having a connection with the main air or
 “brake-pipe, another with an auxiliary-reservoir or
 “chamber for the storage of power, and another with a
 “brake-cylinder or its equivalent for the utilization of
 “the stored power and with a release or discharge pas-
 “sage for releasing the operative power from the brake-
 “cylinder, whether valves governing these passages or
 “connections are arranged in one or more cases and are
 “moved by a piston or its equivalent or by a series of
 “pistons or their equivalents, there being numerous
 “examples in the art of constructions varying materially
 “in appearance whereby these functions are performed,
 “both in plenum and vacuum brake-mechanisms.”

It follows that the Complainants' contention that Boyden's main-valve 22 is an auxiliary-valve, in the sense of patent 360,070, is totally unsound. It is no such thing. Like his feed-valve, his release-valve, and his graduating-valve, it is simply one of the old parts of the old wellknown triple-valve, performing the same old function that it always performed before.

Whenever, in the operation of an automatic air-brake, a valve admits auxiliary-reservoir air to the brake-cylinder, that valve is an essential part of the old triple-valve known in the art long prior to the patent in suit; and it is not the auxiliary-valve 41 of patent 360,070, which does not and cannot perform any such function.

Boyden simply uses the old triple-valve, defined by Mr. Westinghouse as well known in the prior art; and he enables it, as Judge Morris correctly holds (p. 845):

“By an ingenious arrangement restricting the admis-
 “sion of auxiliary-reservoir air to the triple-valve cham-
 “ber, to cause the main-valve to do *both* main-valve
 “work when needed, and to do quick action work when
 “needed.”

THE TWO DECISIONS BELOW.

Judge Morris committed the legal error of holding that claim 2 of patent 360,070 is entitled to cover functional equivalents (p. 846). He evidently based this judgment upon the mistaken idea that patent 360,070 was the first to show a triple-valve piston having, for emergency-stop purposes, a further

traverse than for graduating purposes. He speaks of the "further traverse" as something "unusual" in air-brakes (p. 843); although, as the evidence shows, it is found in triple-valves from the original patent, No. 141,685, to the present time. Indeed, if a triple-valve be capable of venting auxiliary-reservoir air to the brake-cylinder slowly for graduation and quickly for emergencies, there is no other conceivable way in which it can be done than by giving the piston two ranges of traverse, so that it can partially open the main port for the one purpose and fully open it for the other.

His assumption of fact being wrong, the conclusion of law based thereon, of course, falls to the ground.

But if his assumption of fact had been correct, his legal conclusion from such fact would still be wrong, for the following reasons:

First, The *piston*, in its "further traverse," does not *itself* admit train-pipe air to the brake-cylinder; it simply sets in action certain *means* which admit such air, namely, the auxiliary-valve 41 and its by-passage. The specification, by the words "substantially as set forth," makes these means a part of the claim (Seymour vs. Osborne, 11 Wall., 516, 547; Miller vs. Eagle Manufacturing Co., 151 U. S., 186, 202). Indeed, they would have to be read into the claim even in the absence of such words (Mitchell vs. Tilghman, 19 Wall., 391). The claim must always be limited to the means by which the result is effected, and if not so limited in terms or by legal construction it is void. (O'Reilly vs. Morse, 15 How., 62, 119.)

Second, The *specification* of this patent expressly limits the claim to the means by stating that the only invention "claimed" consists in the "*structural features*" (p. 784, line 13) by which the direct admission of train-pipe air to the brake-cylinder is effected, and states that these structural features are composed of the additional valve 41 and its by-passage.

Third, The admissions and erasures made during the prosecution of the application in the Patent Office conclusively limit all the claims to "an auxiliary-valve" (p. 718), and prevent the claims from being construed to cover "a valve integral with the main-valve" for admitting train-pipe air to the brake-cylinder (p. 714).

Fourth, Complainants' counsel, on pp. 40-41 of their brief used in the Circuit Court of Appeals, admit that the "*quick-action attachment* consisting of an air conduit or passage-way directly from the train-pipe connection to the brake-cylinder, and a valve to control it, * * * *is so made the subject matter of every claim in controversy as to give character and effect thereto.*"

We respectfully submit, in view of the authorities above cited and the repeated admissions above referred to, that, whether the "further traverse" were new or old, Judge Morris' construction of claim 2 cannot be sustained.

It is evident from his opinion that Judge Morris has an erroneous conception of the law relating to pioneer inventions, believing that, in some cases, patents for such inventions can be infringed by the use of *functional* equivalents, in the absence of anything like a mechanical equivalent.

This Court has always held the contrary: and the law is so well settled by its repeated decisions that it is difficult to see how anybody can misunderstand it. The very authorities cited by Judge Morris on pages 847, 848 in support of his position are directly against it; and there are many other decisions of this Court on the subject, so clear that misunderstanding would seem impossible. Morse's telegraph was, in the highest sense of the word, a pioneer invention; but, in deciding upon his patent, in *O'Reilly vs. Morse*, 15 How., 62, 119, this Court said:

"Whoever discovers that a certain useful result will be
 "produced, in any art, machine, manufacture, or com-
 "position of matter, by the use of certain means, is
 "entitled to a patent for it; provided he specifies the
 "means he uses in a manner so full and exact that any
 "one skilled in the science to which it appertains can,
 "by using the means he specifies, without any addition
 "to, or subtraction from them, produce precisely the
 "result he describes. And if this cannot be done by the
 "means he describes, the patent is void. And if it can
 "be done, then the patent confers on him the exclusive
 "right to use the means he specifies to produce the result
 "or effect he describes, and nothing more. And it makes
 "no difference, in this respect, whether the effect is pro-
 "duced by chemical agency or combination; or by the

"application of discoveries or principles in natural philosophy known or unknown before his invention; or by machinery acting altogether upon mechanical principles. In either case, he must describe the manner and process as above mentioned, and the end it accomplishes. Any one may lawfully accomplish the same end without infringing the patent, if he uses *means* substantially different from those described."

And the Court held Morse's eighth claim to be void, because it did not specify the means by which the described result was accomplished.

In the recent case of *Miller vs. Eagle Mfg. Co.*, 151 U. S., 186, 201, this Court said:

"It is not the result, effect, or purpose to be accomplished which constitutes invention, or entitles a party to a patent, but the *mechanical means* or instrumentalities by which the object sought is to be attained. . . . Patents cover the means employed to effect results."

Burr vs. Duryea, 1 Wall., 531.

In citing *McCormick vs. Talcott*, *Machine Co. vs. Murphy*, *Valve Co. vs. Valve Co.*, and *Morley vs. Lancaster*, in support of his position on this question, Judge Morris overlooked the fact that this Court, in all those pioneer cases, expressly emphasized the *means as vital* to the question of infringement. Its language is—

"Operating on the same principle and performing the same functions by analogous *means*" (*McCormick vs. Talcott*, p. 405); "at the result, as well as at the *means* by which the result is attained" (*Machine Co. vs. Murphy*, p. 125); "in the Defendant's valve Complaints' exhibit A, the same effects in operation are produced as in the Richardson valve, by the *means* described in Richardson's claim" (*Valve Co. vs. Valve*

"Co., p. 177); "all subsequent machines which employ substantially the same *means* to accomplish the same results are infringements" (Morley vs. Lancaster, p. 273.)

The true rule is that laid down by this court, in Miller vs. Eagle Mfg. Co., 151 U. S., page 207, in the following words:

"The range of equivalents depends upon the extent and nature of the invention. If the invention is broad in its character, the range of equivalents will be correspondingly broad, under the liberal construction which the courts give to such inventions. The doctrine was well stated in Morley Machine Co., vs. Lancaster, 129 U. S., 263, 273, where it is said: 'Where an invention is one of a primary character and the mechanical functions performed by the machine are, as a whole, entirely new, all subsequent machines which employ *substantially the same means* to accomplish the same result are infringements, although the subsequent machine may contain improvements in the separate mechanisms which go to make up the machine.'

Tested by this rule, the patent in suit 360,070 was pioneer *as to the auxiliary-valve 41 and its by-passage*, covering them and their mechanical equivalents, in whatever form they may be used. Westinghouse invented what the Complainants' counsel and the Circuit Court of Appeals for the Fourth Circuit call his "new machine," which he combined with the old triple-valve machine, making two machines combined in one structure; and his range of equivalents is confined to combinations containing his new machine combined with the old well-known machine. If that combination exist in the alleged infringing device, then infringement is established, even though the form of the "new machine" element may be considerably varied from that shown in his patent. But the "new machine" element must be present, in some form or other, or else there is no infringement.

In the New York case, Judge Lacombe properly held the New York Air-Brake Co. guilty of infringement because it used the new machine, the auxiliary-valve 41 and its by-passage, and only varied their form. (See N. Y. device, p. 34, this Brief).

Here, however, the Defendants use the main-valve of the

old triple-valve machine to accomplish the same result *without the presence of the new machine* of the patent in any form whatever; and no court has ever found infringement under such circumstances. To do so would be to discard the whole doctrine of mechanical equivalents and hold that a man can patent results or effects, without regard to the means employed for accomplishing them.

The Circuit Court of Appeals for the Fourth Circuit was right, both as to the facts and the law—*holding*, that the further traverse of the piston was old and usual in triple-valves like those of patent 220,556 (pp. 872, 879, 880); that the Boyden valve 22 is the main-valve of his triple valve, and is not the Westinghouse valve 41 (pp. 881–882); that patents cover only the *means*, or their mechanical equivalents for producing the result, and not the result itself (p. 882); that Boyden's quick-action device is not the mechanical equivalent of that of Westinghouse, but "they * * * differ as widely from each other as two devices for accomplishing the same result can well differ," (p. 880); that prior to the patent in suit Westinghouse had already, in patent 217,838, disclosed the principle of quickening the serial or successive application of the brakes on the several cars by venting the train-pipe at each car (p. 872); that the Court's duty to the public and to inventors at large forbids it to restore to the claim of Westinghouse the matters *which he had erased or virtually disclaimed* at the Patent Office (p. 881), and that the Defendants' device infringes none of the claims of patent 360,070 when the latter are properly construed.

We submit that the conclusion arrived at by the Circuit Court of Appeals is simply impregnable.

We call attention to the fact that Judge Morris and the Circuit Court of Appeals entirely agree on the following points, to wit: That the Boyden valve 22 is the main-valve and not the auxiliary-valve 41 or its mechanical equivalent, and that Boyden accomplishes "quick-action" not by an auxiliary-valve and by-passage, but (p. 845) "by an ingenious arrangement restricting the admission of auxiliary-reservoir air to the triple-valve chamber;" that is to say, by the "partition 9" and the proper proportioning of the old air-passages.

THE DEFENDANTS' DEVICE BROADLY PATENTED TO BOYDEN.

Another consideration of great weight remains to be noticed. The Defendants' device was broadly patented to Mr. Boyden August 16, 1892, *not as an improvement on the Westinghouse device*, but as a new and different means for accomplishing the same result, *operating on a new principle and by a new and different mode of operation*. In the specification of this patent No. 481,134 (applied for September 30, 1889, before this suit was brought), the patent says (p. 1307):

"Efforts have heretofore been made to combine with a
"triple-valve certain *additional* mechanism by which
"train-pipe air could be introduced directly into the
"brake-cylinder in effecting the application of the brakes
"for emergency stops; but in every such instance a sup-
"plemental passage or passages, together with a supple-
"mentary or auxiliary-valve, has had to be employed in
"connection with the triple-valve proper, in order that
"the ordinary functions of the triple-valve might be pre-
"served and the additional function of introducing train-
"pipe air into the brake-cylinder for emergency stops
"might be combined therewith.

"An example of the class of valves referred to in the
"last preceding paragraph *which employ an auxiliary-*
"*valve*, combined with an ordinary triple-valve, is shown
"in United States Patent, to George Westinghouse, Jr.
"dated March 29, 1887, No. 360,070.

"It will be seen that my present invention for intro-
"ducing train-pipe air into the brake-cylinder for emer-
"gency stops *differs essentially* from the device shown in
"the said patent No. 360,070, because I have provided a
"*new principle* of construction and a *new mode* of opera-
"tion, by use of which the desired result aforesaid may
"be produced *without the aid of the auxiliary-valve*
"*heretofore required for the purpose*.

"An examination of the particular embodiment of the
"present invention will disclose the fact that it is a
"triple-valve *per se*, without auxiliary or supplemental
"valve devices, and, further, that its conversion into a
"quick-action valve and its greater capacity for action

“over ordinary forms of triple valves *is due to means which I have invented for retarding or restricting the flow of auxiliary-reservoir air to the main port or passage leading to the brake-cylinder as compared with the more open or free delivery of train-pipe air to the said main port or passage.* * * * And, further, *a single valve—the main valve of the triple-valve proper—is here made to perform the office of opening communication to the brake-cylinder from both the train-pipe and the auxiliary-reservoir in the quick application of the brakes for emergency stops. My invention, therefore, includes any form or structure of valve wherein a single valve admits both train-pipe air and auxiliary-reservoir air to the brake-cylinder in applying for emergency stops, and which structure is provided with means for restricting or retarding the flow of auxiliary-reservoir air to the brake-cylinder as compared with the flow of the train-pipe air thereto.*”

The experienced experts of the Patent Office recognized these statements to be true; and the Commissioner of Patents officially endorsed them as true by granting the patent which contains them, with broad generic claims for Mr. Boyden's new quick-action device—thus adjudicating its entire independence of the Westinghouse device, and holding it to be for a different principle and mode of operation. This action officially puts the Westinghouse patent and the Boyden patent on the same plane with respect to originality and novelty, and in totally different categories as respects the nature of their inventions.

This Court has repeatedly held that such a patent, granted to the later inventor, not as an improvement upon the device of the earlier inventor, but as a new and different way of accomplishing the same result, is evidence of novelty and of non-infringement.

“Consequently such a patent may be, and generally is, received as *prima facie* evidence of the truth of the facts asserted in it. And in cases where the evidence is nicely balanced, it may have weight with a jury in making up their decision as to the Plaintiff's right; and if so, it is not easy to perceive why the Defendant who uses a patented machine should not have the benefit of a like presumption in his favor, arising from a like

"investigation of the originality of his invention, and
 "the judgment of the public officers, that his machine
 "new, and not an infringement of the patent previously
 "granted to the Plaintiff. * * * * The parties should
 "contend on an equal field, and be allowed to use the
 "same weapons.

"The judgment of the Circuit Court is, therefore, reversed,
 "and a *venire de novo* awarded."

CONCLUSION.

In view of the matters herein referred to, we do not see
 how it is possible for any court to reach the conclusion that
 the Defendants' device infringes any claim of the patent in
 suit.

We do not desire in any way to belittle the invention of Mr.
 Westinghouse. While it did not solve the problem of preventing
 "shocks," it did contribute to the art a new and important
 factor which proved to be indispensable to the successful formation
 of quick-action device subsequently invented by Mr. Westinghouse.
 We entirely agree with Judge Lacombe (16 C. C. 371) and the Circuit
 Court of Appeals of the Second Circuit that the devices of patents
 360,070 and 376,837—one the auxiliary-valve and the other the
 supplemental piston—appear to be both essential to the structure
 of a quick-action air-brake embodying the Westinghouse principle
 or mode of operation.

For the purpose of the argument on the question of infringement
 we, therefore, concede the validity of patent 360,070 and the
 importance and value of the invention which it describes.

But there are two different and independent ways of producing quick-action—The one, by adding to the old triple-valve a new auxiliary-valve and by-passage; the other, by peculiarly differentiating the air pressures which bear upon the old triple-valve. Mr. Westinghouse has broadly patented the former, and Mr. Boyden the latter. There is nothing in common between these two ways of accomplishing the result except the old triple-valve, and that is not patentable to either party.

The invention of Mr. Westinghouse just as clearly excludes the Boyden idea, as the invention of Mr. Boyden excludes the idea of Mr. Westinghouse. The patents of Mr. Westinghouse and Mr. Boyden are *both* generic, primary, or pioneer patents each in its own way, and there is no conflict between them. Together, they cover the whole field; separately, each leaves half of the field unoccupied.

Respectfully submitted,

LYSANDER HILL,

Counsel for Defendants.

NOTE.—The attention of the Court is called to a supplemental Brief, by associate counsel, in behalf of Defendants.

ARGUMENT FOR THE BOYDEN BRAKE CO.

Notwithstanding the presumption, arising from the voluminous character of the record, that the questions involved are complex, difficult and unusual; and from the inaccurate and misleading allegations in the Westinghouse Company's petition for the writ of *certiorari*, that the decision of the Court of Appeals in the Fourth Circuit, on these appeals, conflicts with a prior decision of the Appellate Court in the Second Circuit, on the same question, we confidently submit, and shall endeavor to clearly demonstrate, by a comparative examination of the opinions of the appellate tribunals in the Second and Fourth Circuits respectively, and by a concise statement of the controlling

facts governing the decision in the case at bar, that not only is there no conflict nor even a semblance of a conflict between the decisions of the appellate tribunals in the two circuits, on any question adjudicated by either, but in the case at bar there was a single issue involved, *i. e.*, infringement, which was dependent for its solution solely upon whether or not the respective machines of the plaintiff and defendant were alike in principle of construction and operation, or were radically different *quoad* the matters described and claimed as new in the plaintiff's patent in suit. In other words, the questions involved in the case were of the simplest character, the single issue being an issue of fact, *i. e.*, the identity or non-identity of the two machines. True, the determination of this issue of fact is dependent upon the construction to be given to the claim, but that is so in every case.

There was no effort made or argument advanced by the Boyden Brake Co. in the Court of Appeals to dispute, qualify or limit the scope or effect of the decisions in the Second Circuit as *res judicata* on the construction of the claims, but, on the contrary, we relied upon and urged upon the Appellate Court in the Fourth Circuit that the construction and interpretation of the plaintiff's patent, and especially of claim 2 thereof, by Judge Lacombe (65 Fed. Rep. 99, affirmed on appeal), was correct, and that, if accepted as correct and followed by the Court of Appeals in the Fourth Circuit, it required that the latter tribunal should reverse the decree entered by the Circuit Court in the case at bar, which construed the claim 2 aforesaid very differently and inconsistently with the construction given to it in the Second Circuit.

It is proposed in this brief to consider:

I. What was decided in the second and fourth circuits respectively, to determine whether or not there is any conflict between them on the same question.

II. Whether or not there was any error, either of fact or of law, in the decision sought to be reviewed, that in any manner affected or controlled the result,

Before presenting a brief argument on these general questions, it will conduce to a better understanding of the case, if special attention is called to a few leading facts. The bill alleged the grant of a patent to Westinghouse No. 360,070, dated March 29, 1887, and averred that defendant had made and sold air-brakes embodying mechanism that infringed claims, 1, 2 and 4 of said patent; the defense to which was that the machines of the respective parties differed radically from each other, and were in all essential particulars so dissimilar that it was obvious that there was no infringement of claims 1 and 4, and none of claim 2 if the latter was properly construed. The peculiar phraseology of that single claim gave rise to the only really debatable or disputable question in the case.

After hearing on pleadings and proofs, the Circuit Court dismissed the bill as respects claims 1 and 4 on its finding of *fact* that the defendants' device did not contain the mechanisms expressly referred to in said claims and hence did not infringe such claims, but it adjudged in favor of the plaintiffs as respects claim 2 on the theory that although the devices were not structurally the same, but widely different in means employed, they were *functionally* identical; in other words, the learned Judge (Morris, J.) found, as clearly stated in his opinion, that although the Westinghouse *invention* described in the body of the specification was necessarily inclusive of certain characteristic elements, which he did *not* find in the defendants' device either in the same or in any substantially similar or equivalent form, yet (the Court said) the claim was not *in terms* restricted to means, but referred only to the *function* performed, hence he held that it was proper to compare the devices (and he did so compare them) by their functions or results and not by their respective means employed to perform these functions and produce these results. (Hence the remarks found in the opinion of the Court of Appeals on the invalidity of functional claims.) This ruling by the Circuit Court was so obviously contrary to settled doctrine, and erroneous, that defendants appealed from the decision adjudging them to have infringed said 2nd claim; to offset which plaintiffs prayed a cross-appeal for the refusal to sustain their bill as to claims 1 and 4.

Sufficient appears from a comparative reading of the decisions of the Circuit Court and of the Circuit Court of Appeals, in the case at bar, aided by a reference to the colored diagrams annexed to the opinion of the Circuit Court of Appeals, to show conclusively that *both* courts decided that the defendants' device was not only structurally different from, but was not the same in principle of construction and operation, as the Westinghouse patented device; in that the former contained no auxiliary-valve device independent of the main triple valve nor the necessary adjunct in such device of a separate and direct passage way from the train-pipe to the brake-cylinder; hence (as these elements were expressed in the 1st and 4th claims) there was obviously no infringement of those claims. Both courts were in perfect accord on this finding of fact, and the Plaintiff has utterly failed to point out any error in such finding; neither has it been able to point out any error in the finding of either court as to what constitutes the invention disclosed in the Westinghouse patent, even assuming it to be a pioneer patent and entitled to the broadest possible construction. The sole material difference of opinion between the Circuit Court and the Circuit Court of Appeals, and because of which the former was reversed, was in that the former construed the 2d claim more broadly than was warranted by its finding of what constituted the invention disclosed in the body of the specification; and hence was necessarily compelled to compare the devices of the parties litigant by their functions and not by the mechanical means employed, because it found as a fact that such mechanical means were widely different. No one can read the opinion of the Circuit Court without being impressed with the belief that had it not erroneously construed said 2d claim, but had construed it to be broadly for means auxiliary to and independent of the main-valve of the triple-valve, actuated "by the (usual) further traverse of the piston" of the triple-valve, (as the *invention* is defined in the patent, as it is defined in the opinion of the Circuit Court of Appeals, complained of, and as it is defined in the opinion of Judge Lacombe in the Second Circuit, 65 Fed. Rep. 99), the Circuit Court for the District of Maryland would have held *as a fact* that the defendants' device in the case at bar did not involve such invention or its elements or anything substantially equivalent thereto, and hence did not infringe said *second* claim.

It will lighten the labor of investigation by this Court if we refer to the petition for the writ of certiorari, filed by the Westinghouse Company, to ascertain in what particulars they deem the decision of the Court of Appeals to be erroneous.

Their allegations are: That there was a prior adjudication in the Second Circuit (65 Fed. Rep., 99), in which claim 2 of this patent was adjudged to be valid. That in the case at bar the Circuit Court of Appeals for the Fourth Circuit "has adjudged and declared that said second claim is invalid and does not cover subject matter which can be lawfully claimed;" and hence, that there is a conflict of decision on the same question.

It is respectfully submitted that the Court of Appeals has not so decided, and that the decision has evidently been misunderstood or misinterpreted by the petitioners; the adjudication being in effect that if claim 2 is to be construed (as the Circuit Court held and applied it) for a function or result irrespective of the means employed to perform such function or produce such result, it is "fatally defective," but the following paragraphs of the opinion clearly show that the Court construed it by implying the means, by force of the concluding words, "substantially as described;" and, hence, reversing the Circuit Court on its finding of law, in the construction of the claim, affirmed it on its finding of fact that the plaintiffs' machine as so defined, was neither the same as, nor substantially similar to, the defendant's machine either in principle of construction or in mode of operation. In the petition it is said—paragraph 13—that said second claim is of great value and importance. A reference to Judge Lacombe's opinion in the Second Circuit (65 Fed. Rep., 99) will show that it is of comparatively minor importance, and merely inclusive of a modified form of the device covered by the first and principal claim.

It is said in the petition page 6, that "the invention of the patent in suit, No. 360,070, is one which is used on upwards of 400,000 freight cars at the present time," etc. As this paragraph was evidently inserted for the purpose of impressing this Court with the belief that the subject matter of this litigation was of sufficient value and importance to warrant this Court in reviewing it on that ground alone, it is proper to reply to said statement by the remark that the same is wholly incorrect and misleading. What the petitioners meant to say or ought to have

said, is that the device of the later patent, No. 376,837, referred to in the 9th and 10th paragraphs of the petition (which said patent is for an operative and highly useful and successful improved quick-action brake embodying some of the features and principles of their earlier patent, No. 360,070,) is so "used on upwards of 400,000 freight cars at the present time," because it was proven in the case in the 2d Circuit and also in the present case in the 4th Circuit, that the device of the patent here in question is not now made by the petitioners and has not been made or sold by them since 1887 when they adopted the device of the later patent, No. 376,837, as their standard form. The defendants alleged that the manufacture and sale of No. 360,070 was abandoned by the petitioners because of its radical defects; on the other hand the petitioners allege that it is not defective, but that the later device is better for their purpose. We leave the Court to draw its own conclusion on this point; (which, however, is not material in the present inquiry) from the remarks of Judges Townsend and Shipman on that question (65 Fed. Rep. 99 and 69 Fed. Rep. 715) and Record, page 149, Ans. to X-Qs. 163 to 167.

These two New York cases are also instructive in showing what view the court and the plaintiffs in those cases entertained and enforced as to the utility and scope of the invention of patent 360,070, which was *not* in suit therein, but was set up by the defendants therein as anticipating and qualifying the later patent—376,837—on which said case was founded. After the decisions in said case the plaintiffs brought a suit on both patents, including 360,070, the opinion in which, on motion for preliminary injunction, was written by Judge Lacombe and is reported—65 Fed. Rep., 99. That case was founded on both patents, Nos. 360,070, March 28, 1887, and 376,837 dated January 24, 1888.

It is to be noted that of these patents, the second one, No. 376,837, is the *only* one that had *then* been favorably adjudicated.

Each of the aforesaid patents are for "auxiliary-valves" *additional* to the triple-valve, and operating to open *independent* ports and *passage-ways* leading directly to the brake-cylinder. In 360,070 the auxiliary-valve is opened by means of the triple-valve piston acting *mechanically* on it (as both the

New York courts said of it.) In 376,837 the auxiliary-valve is opened by auxiliary-reservoir air pressure acting on a supplemental piston, and not mechanically by the triple-valve piston. (See Rec., page 153, X-Q. and Ans. 182.)

It will be seen that in both of these Westinghouse patents train-pipe air is admitted to the brake-cylinder through an *independent* passage controlled by an "auxiliary-valve" *additional* to the "triple-valve"—the difference between these patents is merely that each has its own specific means to open the said "auxiliary valve."

In order to a proper understanding of exactly what the decision complained of determines as adjudicated matters of law and fact, we may best reach a correct conclusion by inquiring (a) what in general terms is the invention patented; (b) what in general terms is the device of the defendant alleged to infringe; (c) why the Circuit Court, as well as the Court of Appeals, held that the latter was not substantially similar to the former in respect of the matter of claims 1 and 4 as to which the bill was dismissed in the first instance; (d) what construction of claim 2 was proper and allowable under the broadest interpretation that could be given to it in view of the descriptive matter in the specification and the file and contents of the application; (e) that the construction so given to it was entirely consistent with, and, indeed, exactly the same as given to it by the courts in the Second Circuit; and (f) that, although under the *same* construction of claim 2 by the appellate tribunals in the Second and Fourth Circuits, respectively, the device of one defendant was adjudged to infringe, while the device of the other was held not to infringe, this result was not due to any conflict or contrariety of decision between the two courts *as to the proper interpretation of the claim*, but was due solely to the fact that the respective devices of the two defendants were totally different from each other, in that while the Boyden Brake Co.'s device did not contain the invention of the second or any other claim of the Westinghouse patent, as the said claims were defined by either the Courts of Appeals in the Second or the Fourth Circuit, the device of the defendant in the Second Circuit *did* contain the invention as so defined in *all* the claims. Hence, the alleged variance is not a conflict of decisions, as to a question of law or the construction of the claim, but a difference of finding,

and a proper difference of finding, of *fact*, on the issue of infringement only in the two cases, respectively; and necessarily so because in the one case the Westinghouse invention was compared with a device substantially identical with it, while in the other case it was compared (under the same interpretation of the claims) with a device which was totally different from it.

And this difference between the devices of the respective defendants in the two cases will be apparent at once on a comparison of the colored diagrams of the said devices annexed to the opinion complained of, in connection with the opinion of the Circuit Court and the Circuit Court of Appeals for the Fourth Circuit defining the Boyden Brake Co.'s device (Proceedings, page 877), and of the Circuit Court (Lacombe, J.) defining the New York Air Brake Co.'s device (opposite page 883).

A BRIEF COMPARATIVE EXAMINATION OF THE PLAINTIFF'S AND DEFENDANTS' MACHINES.

The marked differences in principle of construction and operation between the Plaintiffs' and Defendants' machines respectively, should be clearly understood, and when so understood the propriety and correctness of the decision of the Circuit Court of Appeals for the Fourth Circuit will be apparent at once.

COMPLAINANT'S MACHINE.

By reference to the Plaintiffs' patent, and to the several decisions explaining and defining the invention, both in the Second and Fourth Circuits (which are entirely in accord on this subject), we find that it consists of a brake device, having for its foundation or principal element in the new combination, a triple-valve device such as is described in the old and expired Westinghouse patent No. 220,556. This device operated to admit air pressure to the brake-cylinder solely from the auxiliary-reservoir. To this device, as so constructed and operated, AND WITHOUT CHANGE THEREIN, EITHER IN ITS PARTS OR IN THE MODE OF OPERATION OF ITS PARTS, or in any of the triple-valve functions performed thereby, the patentee of 360,070 (the patent in suit) *added* two elements, viz., an auxiliary-valve (marked 41) and a passageway (marked 46) controlled thereby. This valve 41 was purely *auxiliary*, both in mechanical construction and mechanical operation; hence (as stated in the patent) it was *independ-*

ent of the main valve, and could be plugged up without in any manner affecting the action of the triple-valve, or any of its parts or passages. This valve 41 and passage 46 are shown in the red coloring on the diagram (proceeding page 877) annexed to the opinion of Judge Hughes in the Court of Appeals, and are thus brought out clearly so as to be sufficiently understood. Indeed, so distinct and segregable are the new *added* parts from the old triple valve parts of patent 220,556 that the Counsel for petitioners, in their briefs in the Circuit and Appellate Courts, described the new device as *two* machines enclosed in one case or box, the new part (or machine) being brought into action by the old under certain conditions.

The exact language of the statements referred to, in the Westinghouse brief, is as follows :

"Westinghouse added to and combined with the brake
 "(the automatic brake of the prior patents, Nos. 220,556)
 "another brake mechanism. * * * And he so com-
 "bined these two mechanisms, "the service" and the
 "quick-action," that while, in fact, they constitute *two*
 "*machines*, they are also included in a *single structure*.
 "(The italics are in the original.)"

And again :

"Thus it will be seen that this quick-action attach-
 "ment, *consisting of an air conduit or passage-way*
 "*directly from the train-pipe connection to the brake-*
 "*cylinder, and a valve to control it*, such valve itself be-
 "ing under control of the triple-piston and so combined
 "with the old automatic brake appliances that not inter-
 "fering with the ordinary use of the latter it, the quick-
 "action attachment, may be used as an auxiliary emer-
 "gency device in the presence of great or serious danger—
 "that *this*, the chief novelty and element of utility of
 "the Westinghouse invention now in controversy is so
 "made the subject of *every claim in controversy* as to
 "give character and effect thereto, etc. (The italics are
 "*not* in the original.)"

The counsel, in the foregoing statements, undoubtedly made a correct exposition, both as to the character of the apparatus patented by Westinghouse and the scope of the claims therefor. We do not dispute either proposition, because it accords exactly with the patentees statement contained in the Patent, in which after elaborately describing the prior automatic brake (of patents 220,556 and others), he says :

"So far as hereinbefore described, the triple-valve "accords in all substantial particulars with, and is "adapted to operate similarly to those of my letters "patent Nos. 168,359, 172,064 and 220,556, and in order "that it may perform the further functions requisite in "the practice of my present invention, it is provided with "certain *additional members*."

He then proceeds to tell us in plain English words that do not admit of doubtful meaning, that these *additional members*, consist of "an auxiliary-valve, 41 (which) is connected to and moves with the stem, 36, said valve working over a face on the bushing, 37, between the piston chamber, 11, and drain cup 19 and governing a port, 42, in said face leading into a chamber, 43, adjoining the same."

Opposite is a diagram of the patented device, taken from the patent drawing, the new parts being colored in red to show quickly to the eye exactly what are the "additional members" and what is the relation they bear to the old parts—the triple-valve proper. In its operation the course of the auxiliary-reservoir air through the old main-valve (*black*) of the triple-valve is shown by a yellow line, and the course of the train-pipe air through the new "auxiliary-valve" device is shown by a blue line. Thus in the Complainant's structure, *two* machines are required to perform the two functions.

Now, how are the *auxiliary-valve* 41 and passage 46 constructed? what relation do they bear to the triple-valve device? how are they combined therewith? whether they may be integral therewith or must they be segregated therefrom? and how is the auxiliary-valve actuated, or rather *governed*, by the old device to which they are *added*? This is the key to a correct understanding of the invention of the new combination patented. Everybody agrees that, as shown and described, the *new* parts are physically distinct and separate from the *old* parts, to which they were added and are operated by the *usual* further or extreme traverse of the triple-valve piston (of the old 220,556 device), the stem thereof striking the valve 41 (colored red) on such further or extreme traverse and unseating it, hence uncovering the passage 46 (colored red), which leads from the train-pipe *direct* (and not through any port passage or chamber of the old triple-valve element), train-pipe air will pass directly to the brake-cylinder.

Complainants Structure of Patent 360,070

With the Valves in the Quick-Action Position.

The course of the Auxiliary Reservoir Air through the old Main Valve (black) of the Triple Valve is shown by a yellow line, and the course of the Train Pipe Air through the new "Auxiliary Valve" device is shown by a blue line. Thus in the Complainants structure, *two* machines are required to perform the two functions.

In the light of the evidence presented by this record, how can the patent in suit be classified or treated as a pioneer patent? Both in its general and in its particular descriptions the invention is referred to in the patent as consisting of a novel combination of mechanisms, the major portion of which is admittedly old. We were told by the learned counsel for the complainant, in their printed briefs in the Circuit and Appellate Courts, and truthfully told, that the invention in question consists really of two machines in one—two separate and distinct machines—the new element wholly separate and distinct, both functionally and physically from the main (the triple-valve) mechanism. Not a single one of its elements is connected, physically or otherwise (except that they are both in the same casing) with the main machine; not a single element of it plays any part in the performance of the work of the main machine, nor do they alter, add to, affect or vary in the most remote manner the function or operation or result of the main machine as a triple-valve proper. The latter remains in this new combination, as an element thereof, with the *same* mode of operation as it always had, precisely as it is described in the previous expired patent, No. 220,556, granted to Westinghouse. In other words, the present invention is built upon the triple-valve of this prior patent, without any change whatever in *its* construction or in the mode of operation of any of its parts. In the words of the patent in suit, the invention consists of the old triple-valve of patent 220,556, “provided with certain *additional* members,” which the specification shows are auxiliary thereto, but mechanically independent therefrom, in order that these additional members may be actuated by the other and old element under certain conditions—*i. e.*, when its piston makes its old “further” or full traverse and so contacts with and moves the valve of the added machine, which produces an additional function.

Now, what is this additional function, and what is the new result obtained or sought to be obtained? The former is described generally as the admission of train-pipe air direct to the brake-cylinder; and the latter as quickening the action of the brake, as the chief object. Let us see what is the effect of the admission of the train-pipe air direct to the brake-cylinder. It is certainly not a quickening of the action of the valve itself.

The triple-valve of patent 220,556 is undeniably as quick in action—as a single valve—as the machine of the patent in suit. What is meant by “quick action” is quick *serial* action of a number of such valves placed in sequence under the cars of a train; and this quickening of action is effected because the discharge of train-pipe air *at each valve* hastens the action of the succeeding valve; in other words the train-pipe is vented *at each valve*, instead of (as in the old automatic brake) at the one opening, at the engineer’s valve on the engine. But did the patent in suit, for the *first* time, disclose this underlying principle of quick action or quick serial action? Assuredly not; as the record clearly shows (page 666).

It is fully contained in an earlier patent, No. 217,833, dated July 22, 1879, granted to Mr. Westinghouse, in which he said (p. 759):

“It sometimes happens with such brake apparatus, especially in case of accident, that material advantages could be effected by having all the brakes of the train applied or brought into action *simultaneously*, or *nearly* so as possible. To accomplish this it is only necessary to make provision for the simultaneous opening of one or more ports in the air-conduit passages at points not remote from each auxiliary-reservoir.”

And this description in the patent follows a reference to the applicability of that principle and that invention to the triple-valve or automatic brake. Now, this fact is of prime importance because, while this old patent does not, nor do we pretend that it does, disclose the *mechanism* of the patent in suit, it does disclose the principle of serial venting of the train-pipe at each car, which underlies and characterizes the invention of the patent in suit, and deprives it of all semblance of right to be classified as a pioneer patent for quick serial action.

It is very important that your Honors should give due weight to this evidence of the condition or prior *state of the art*, because it affects, to a certain extent, *the range of equivalents* to which the patent in suit may be entitled. And the condition of the art, disclosed by this prior patent, No. 217,833, as well as by the triple-valve patent, No. 220,556, lies at the very threshold of the enquiry in this, as in all other cases, as to what is legally included within the claims, wholly apart from and in addition to the descriptive limitations in the body of the specification of the patent in suit.

No one can read the specification of the patent in suit, without reaching the conclusion that the *essence* of the invention consists (as admitted by counsel in the extracts above quoted from their Circuit and Appellate Court briefs) in combining *two separate and distinct* machines, one old and the other new, the latter in no manner a part of the old device, mechanically or functionally.

DEFENDANT'S MACHINE.
(See diagram opposite following page.)

On the other hand, the defendants machine does not consist of two machines combined, but of one machine, and that the old one, improved and improved in a part which never before, by any one in the world, was ever thought could be improved or modified, viz. by separating the triple-valve chamber into two chambers communicating with each other through a small opening; in plain words, inserting a *bushing or partition* therein and so producing *differential pressures* in the chambers C and D on either side of said partition, thereby having a high pressure in piston chamber D (70 lbs.) to hold the piston back, and a lower pressure in the valve chamber C (about 5 lbs.), thus permitting the train-pipe air (shown by a blue line) at 55 lbs.) to open the feeding-in valve of the triple-valve, and passing into the chamber C, therein commingling with auxiliary-reservoir air (shown by a yellow line), and *both* airs passing together to the brake-cylinder, through the port opened by the *old* main-valve 22 (black) of the original triple-valve. In other words making *one* valve, the said main-valve 22, perform the *two* functions of simultaneously admitting both airs to the brake-cylinder. This was more than an invention; it was a discovery, a revelation of the latent powers of the old machine, made wonderfully effective by the most simple change, and in a part of the device never before attempted to be modified, and which the skill of the mechanic would never suggest to him to alter, add to or modify to produce the effect sought for. The means adopted to produce the primary result obtained, *i. e.*, differential pressures, producing the desired secondary effect, could never be *reasoned* out from anything then known in the art; certainly not from anything contained in the plaintiffs' patent. It was a great invention, and the widest possible departure from the principle on which 360,070 is constructed, wherein *two* (the old and a new) machines are required,

Opposite is a diagram of the defendants' device. In its operation, the course of the auxiliary-reservoir air, through the port opened by the old main valve 22 (black) of the triple-valve, to the brake-cylinder, is shown by a yellow line, and the course of the train-pipe air, commingling with the auxiliary-reservoir air and passing together through the same old main-valve port, to the brake-cylinder, is shown by a blue line, thereby utilizing the old main-valve 22 of the triple-valve to perform both functions. Thus in defendants' structure only *one* machine, the old triple-valve, is required to perform the two functions.

Let us critically examine it. We have seen that Westinghouse started with the old triple-valve and *added* new valve parts, forming a second machine, which are physically segregated from the old, and only brought into action when (under a great release of pressure in the train-pipe) the movable part (the piston) of the old makes its *usual* full (further) traverse, which causes it to *contact with* the movable element (the valve 41) of the new or *added* parts. Now, on the other hand, Mr. Boyden also started with the old triple-valve, and desiring to accomplish the same final (secondary with him) *result* as Westinghouse (which he had a perfect right to do if he did it by substantially different *means*), viz., admit train-pipe air as well as reservoir air to the brake-cylinder, he devised entirely novel means to produce that result, not by *adding* any auxiliary-valve nor any additional passage-way controlled thereby, but he utilized *the same passage-way and the same valves* of the old triple-valve to perform the double function, viz: (a) Its old function of admitting reservoir air, and (b), the new function of admitting train-pipe air; and he did this by means of ingeniously partitioning the old triple-valve chamber so as to produce *differential pressures* therein under the conditions required, which said means (the subject of Boyden's patent 481,134) are so obviously different, not only structurally but in principle of construction and operation from that of the Westinghouse device of patent 360,070, that both the Circuit Court for Maryland and the Court of Appeals for the Fourth Circuit unhesitatingly so found *as a fact*. Both courts concurred in finding that claims 1 and 4 of patent 360,070 (which *expressed* the necessary features of that device) were clearly not infringed,

Defendants Structure.

With the Valves in the Quick-Action Position.

The course of the Auxiliary Reservoir Air, through the port opened by the old Main Valve 22 (Black) of the Triple Valve, to the Brake Cylinder, is shown by a yellow line, while the course of the Train Pipe Air, which commingles with the Auxiliary Reservoir Air in the Valve Chamber C and passes through the same port to the Brake Cylinder, is shown by a blue line. Thus in Defendants Structure only *one* machine, the old Triple Valve, is required to perform the two functions.

The Circuit Court says, in its opinion (p. 844):

"In the Boyden mechanism, which is alleged in this case to infringe, I have not been able to satisfy myself that Boyden makes use of an auxiliary-valve in the sense in which the term is employed in the specifications, and some of the claims of the patent No. 360,070 "in suit."

And again he says (p. 844):

"So, I take it, that the defendants' valve i, k, j (40) must "be held to be the *sensitive graduating valve* usual in "triple-valve devices since the Westinghouse patent No. "220,556; and the Defendants' valve 22 must be considered to be the main valve, and that in defendants' "mechanism he has been able, by an ingenious arrangement restricting the admission of auxiliary-reservoir air "to the triple-valve chamber, *to cause the main valve* to "do both main-valve work when needed and to do quick-action work when needed."

The learned judge, having thus found as a *fact* that the Boyden machine did not contain the elements which distinguished and characterized the novelty of the Westinghouse machine, now, why did he hold that Boyden's device infringed the *second claim* of 360,070 (and not the first and fourth), and why did the Court of Appeals for the Fourth Circuit concur with the Circuit Court in its finding of non-infringement of claims 1 and 4 and differ with it as to claim 2 and reverse its finding as to the construction of claim 2 and the issue of infringement based thereon?

The answer is very easily ascertained from the face of the two opinions without searching the record; and upon them we can safely rest a conclusion as to whether or not the decision of the Court of Appeals for the Fourth Circuit, complained of, is correct. That answer is to be found in the following facts; and they show conclusively, not only that the decision of the appellate tribunal was correct, but that it is in full accord with the decisions in the Second Circuit *on the same question, i. e.*, on the construction and interpretation of claim 2. These leading facts are as follows:

1. As before stated, the devices of both parties litigant are founded upon and evolved from, the old triple-valve (shown in prior expired patents). That old device contained a piston which actuated a main-valve; that piston in the device of 220,556 and others had *two* traverses, one a preliminary or partial

traverse for a part of its possible throw, and the other a further or final or continued traverse for the full extent of its possible throw. The *main-valve* of the triple (of 220,556) had as an adjunct a sensitive graduating-valve mounted within it, which was first moved by the partial traverse of the piston and opened a port through the main-valve, for ordinary or "graduated" braking, such partial or preliminary traverse of the piston (whether it was sufficient to move the graduating-valve and the main-valve or the former only) was sufficient to do all the *graduated* work required, *i. e.*, let enough air pressure enter the brake-cylinder; but when full or maximum pressure was *quickly* desired the piston was given its full or further traverse, and the main-valve then included and performed the whole work, which was commonly denominated an "emergency" application of the brakes. This explanation is *essential* to bear in mind, in order to have it clearly understood that the triple-valve piston of the old device of 220,556 had not only a *preliminary traverse*, but a *further traverse*, precisely as it has, and no other than it has, in the improved device of the patent 360,070 here in suit.

With this explanation let us look at the second claim, italicizing it as the Court of Appeals did:

2. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary-reservoir to the brake cylinder, *and which by a further traverse admits air direct from the main air-pipe to the brake-cylinder*, substantially as set forth.

The Circuit Court obviously construed this claim improperly, for two reasons: (a) because it erroneously, or rather mistakenly, found as a premise that the "further traverse" in and of itself was a new and "unusual" traverse of the piston. It has been clearly shown that it was not new and unusual, but precisely the same "further" traverse that it always had. The claim in question is an exact description of the old automatic brake and the old triple-valve of patent 220,556 (patents for same having expired) in its statement of the elements and in its statement particularly of the preliminary and further traverses of the triple-valve piston (the former for graduating and the latter for emergency service), the said claim stating nothing new quoad the old device of patent 220,556, except the "result" obtained

by such *further* traverse in this new combination, viz: "Admits air *directly* from the *main air-pipe* (train-pipe) to the brake cylinder;" and, as these words were followed by "substantially as set forth," of course some *means* (even generically considered) *of the character described in the specification* were to be read into the claim by implication, as otherwise it would be obviously void as claiming a mere result or function. Now this is exactly what the Court of Appeals did. It found that the Circuit Court was wrong, and confessedly (by reference to prior patent 220,556) obviously wrong, in supposing that the "further traverse" mentioned in the claim was "new and unusual;" and this being so, that if the claim was to be interpreted literally to include a combination comprising no other elements than those named (all of which were old separately and in the same combination and acting as such only in the old way) that the claim, as thus construed, could not be differentiated from the prior art, except by the words "admits air direct from the main air pipe to the brake cylinder," which was clearly claiming a "function" or "result" and not the means, and particularly not the means pointed out in the specification to produce the result named.

But the Court of Appeals did not stop there, nor did it adjudicate that the claim was necessarily to be adjudged invalid and void, or "fatally defective," under any and all possible constructions of it, as mistakenly averred by the Westinghouse Company's counsel in the petition for certiorari.

The Court of Appeals having found, and correctly found, that Judge Morris was in error in supposing that the "further" traverse of the piston, referred to in the claim, was new, there was nothing left in the claim, descriptive of the new parts of the machine, except the words "admits air directly from the main air-pipe to the brake-cylinder," which it is useless for anybody to deny are descriptive only of the "result" sought for, and not of the means to produce that result. The Court of Appeals having thus corrected Judge Morris in his finding of *fact*, in this regard, of course was obliged to reject his standard of comparison of the two machines—i. e., a comparison of them by their functions or results, as a whole, and not by their mechanisms; and proceeded to determine for itself what was the true interpretation of the claim.

In doing so, Judge Hughes is careful to state (which statement would otherwise be wholly unnecessary) that—(p. 877):

“The phrase ‘substantially as set forth’ is technical, and equivalent to saying ‘by the means described in the text of the inventor’s application for letters patent, as illustrated by the drawings, diagrams and models which accompany the application.’ These words limit the general terms of the specification which set out the *function* performed by the invention, and confine the inventor’s rights to his own *means* or their mechanical equivalent of performing the function.”

(The italics are the Court’s and appear in the Opinion.)

Now, having shown that the Circuit Court erred first in its finding of fact that the “further traverse” of the piston, spoken of in the claim, was “new and unusual,” and hence necessarily erred in its construction of the claim based on such mistake in fact, the Court of Appeals proceeded thereupon to show, as stated, that if it construed the claim without any limitations and literally upon what was new in it, it would perforce be obliged to hold the claim fatally defective as covering a result only, because the statement of the result (“admits air directly, etc.”) was the only new thing stated in it, and hence that under such construction it would be acting contrary to settled doctrine if it held the claim to be otherwise than “fatally defective” under such conditions. But it did not make any such *adjudication*, because it proceeded to discuss the effect of the words “substantially as set forth,” holding that “these words limit the general terms which set out the *function* and confine the inventor’s rights to his own *means* or their mechanical equivalent of performing the function.”

Hence the Court of Appeals proceeded to ascertain and determine what were these *means* and to give a broad and general definition thereof, limiting them only by the absolutely necessary limitations inherent in the device itself, and as expressed in the specification. The learned Judge’s “Statement of the Case” preceding the opinion, and the opinion itself, clearly show this to be so. In the former he said (p. 875):

“To repeat, his (Westinghouse) device for this purpose consisted in attaching to the pre-existing triple-valve, as patented in number 220,556, a machine which embraced an additional stem, an additional valve and additional air-passages leading from the port in the

"new valve to the brake-cylinder. This new attachment is put into action for emergency purposes by the triple-valve piston when on its extreme traverse. The previous machine, 220,556, had provided for the extreme traverse of that piston by which it had put in action the main-valve at the end of its old stem, and opened a full and direct flow of compressed air from the auxiliary-reservoir into the brake-cylinder for use in emergencies. Thus the new contrivance, by the *same* extreme traverse of the triple-valve piston, continued the old flow of compressed air for emergency purposes and provided an additional flow of the air for emergency purposes by an additional mechanism; this latter flow being directly from the train-pipe, and the former flow being from the auxiliary-reservoir. Such was the make-up of patent 360,070—two machines in one box or case."

Preceding the above-quoted paragraph the Court of Appeals took occasion in defining the old triple-valve of 220,556 to say (p. 873):

"With this brake of patent 220,556, gradual stopping and slowing was executed by giving the piston a partial or half-traverse in its chamber, by which air passed through the sensitive-valve on the stem of the piston to the brake-cylinder; and emergency stopping was done by a full or extreme traverse of the piston in its chamber, which closed the sensitive-valve in its stem and opened the main-valve fixed upon the end of the stem, and allowed a full and direct venting of air from the auxiliary-reservoir into the brake-cylinder."

And also remarking in succeeding paragraph the following (p. 874):

"In the Westinghouse Automatic Air-brake, as patented in number 220,556, the ordinary work of braking was performed by a partial traverse of its chamber by triple-valve piston, graduated, according to the purpose desired, at the will of the engineer; and emergency work was done by an extreme traverse of the piston to the end of its chamber. * * * The text and diagram of 220,556 show that even a full or extreme traverse of the piston in its chamber would vent no other compressed air into the brake-cylinders except from the auxiliary-reservoirs."

Having thus defined the prior art (as shown in the patent 220,556), and conclusively established that the Circuit Court was mistaken in saying that the "further traverse" of the piston

was "new and unusual," and having also shown thereby that every element both separately and in the same combination, and their and its mode of operation, *expressed* in the second claim, was old, the learned judge, speaking for the Court of Appeals, proceeding to detail the evolution of the two devices of the Plaintiffs and Defendants herein, said, in the following extract from succeeding paragraphs (p. 874):

"It is admitted on both sides that while the mechanism "220,556, though effective for the ordinary purposes of "braking, was not effective for abruptly stopping long "trains in sudden emergencies. This deficiency of the "Westinghouse brake, in the stage of improvement which "it had reached in patent 220,556, created the necessity "for some additional invention whereby could be accom- "plished an instantaneous and simultaneous application "of all the brakes of every car.

"Each of the chief contestants in the present suit set "himself laudably to work in devising a means to "accomplish this important desideratum, each taking the "air-brake, patented as numbered 220,556, Westing- "house's exclusive property in which has expired, as the "basis of his new device, the common object being to "produce a mechanism by which to secure instantane- "ously, whenever and only when a sudden emergency "arose, such a quickened discharge of compressed air "into the several brake-cylinders that each car would "simultaneously, and the entire train as a whole, be "brought to a sudden halt, but leaving all the mechanism "already existing for use in ordinary braking unmolested "and unchanged. Westinghouse devised for each car an "additional valve, which he so attached to the triple-valve "of patent 220,556 that when the piston should be in "complete traverse and driven to the end of its chamber, "it should drive forward an additional stem provided for "this additional valve, and thereby open a port in that "valve by which compressed air from the train-pipe "should pass, through by-passes independent of the "triple-valve, into the brake-cylinder into which the "triple-valve vented compressed air from the auxiliary- "reservoir. By this device of the additional stem, the "additional valve and the independent by-passes into "which the latter opened, the inventor contrived to dis- "charge compressed air from both the auxiliary-reservoir "and the train-pipe into the brake-cylinder of each car "simultaneously, and thereby so quickened the action of "the brakes as to accomplish the desideratum of quick "action.

"Boyden also made a successful invention of venting compressed air from the train-pipe into the brake-cylinder of each car, simultaneously with venting air from the auxiliary-reservoir to the brake-cylinder, as had been done for emergency purposes by the previous triple-valve of patent 220,556. He did not resort to a second machine. He did not devise an additional stem, an additional valve, or by-passages independent of those of the triple-valve. He accomplished the transmission of compressed air directly from the train-pipe to the brake-cylinder by other means."

The foregoing quotations are from the "statement of the case" preceding and made a part of the opinion proper. In the latter, comparing the Plaintiff's and Defendant's devices, the Court said (p. 878):

"The same result was accomplished by the two devices, but these had but one means in common. Each used one common mechanical movement of the main piston, which was a movement described in the patent which had expired. But the further mechanism employed, respectively, by the two inventions were, respectively, as has been described.

"The transmission of train-pipe air and auxiliary-reservoir air simultaneously to the brake-cylinder is a result or function, and is not patentable. The means by which this or any other result or function is accomplished may be many and various, and if these several means are not mechanical equivalents, each of them is patentable. The question at bar is, whether Boyden's brass-ring partition with the port it contains, inserted in and made a part of the triple-valve itself, successfully accomplishing the function of discharging train-pipe air into the brake-cylinder simultaneously with the triple-valve's discharge of auxiliary-reservoir air into that cylinder, is the mechanical equivalent of Westinghouse's attached machine, non-integral, segregate and individual, consisting of another stem, another valve and by-passages peculiar to itself leading from the additional valve to the brake-cylinder, both devices being put in action by the triple-valve piston when on its old extreme traverse."

Can anything be plainer than that the Court of Appeals *adjudicated*, not that the 2d claim was void if properly construed, but that it should be construed (and properly so) as a claim for the *means* of producing the result stated in the claim? And, so construing it, the Court said (p. 880):

"Comparing the two devices apart from the triple-valve piston in extreme traverse, we are unable to entertain a doubt that the ruling of the Patent Office was correct to the effect that Boyden's device was not the mechanical equivalent of that of Westinghouse. They seem to us to differ as widely from each other as two devices for accomplishing the same result can well differ."

If it had meant to say, and had adjudicated, that the said 2d claim was fatally defective and void, under any permissible interpretation of it (as the plaintiffs mistakenly asserted in their petition for *certiorari*), there would have been no necessity for saying, and indeed it would have been surplusage to say, on the issue of infringement, the matter quoted in the above paragraph.

And this finding of fact by the Court of Appeals differentiating between the two devices in question, and adjudging their non-identity as mechanisms, is in full accord with a like finding of fact in the case at bar, by the Circuit Court, as will appear from the following quotation from the opinion of that Court (p. 844):

"In the Boyden mechanism, which is alleged in this case to infringe, I have not been able to satisfy myself that Boyden makes use of an 'auxiliary-valve' in the sense in which that term is employed in the specification and in some of the claims of the patent No. 360,070, now in suit. It appears from the specification of patent No. 360,070 that what Westinghouse meant by the 'auxiliary-valve, which is made one of the elements of the combination in the first and fourth claims, is such a valve as he has described in his specification, and which is independent of and performs none of the functions of the main valve of the ordinary triple-valve device."

Thus it is demonstrated to an absolute certainty that claim 2, in order to make it a claim for anything but the "result" sought for, i. e., "admits air directly from the main-air-pipe to the brake-cylinder," must be construed by implying the *means* to produce that result, and hence, is inclusive of means which are "auxiliary" to the triple-valve and "independent" of the main valve thereof; and these quoted words are the only limitations which the defendants sought to apply; and they are

required not only by the principle of construction and operation of the device, apparent on the face of the patent itself, but by the matters appearing in the file and contents of the application therefor.

Indeed, the plaintiffs, while now shifting their position, conceded these limitations in the Circuit and Appellate Courts, in the extracts already quoted herein from their brief in those Courts. (See quotation page 9 of this argument).

In corroboration of its conclusion stated, the Court of Appeals took occasion to remark that the decision of the Patent Office in granting a patent (No. 481,134) to defendant (Boyden) for his device was corroborative evidence of the non-identity of the device of the Defendant with that of the Plaintiff. The Court was very careful to say that this was only evidence, and was not conclusive. For the purpose of proving non-identity the Defendants' patent was admissible as evidence, and properly considered as such, in view of the decisions of this Court in *Corning vs. Burden*, 15 Howard, 252, and *Miller vs. Eagle Co.*, 151 U. S. 186 (208), in which latter case this Court said:

"Again, the issuance of the patents to (Defendants' assignors) creates a prima facie presumption of a patentable difference from that of the Plaintiff's patent."

In concluding its opinion, the Court of Appeals properly examined and considered the decisions in the Second Circuit, in which the same patent 360,070 was in controversy as the foundation of the suit, in which the opinion by Judge Lacombe (65 Fed. Rep. 99) was affirmed by the Court of Appeals, in a per curiam opinion (69 Fed. Rep. 715).

Judge Lacombe's opinion in that case (p. 101 of the report) quotes the first claim of patent 360,070, and in discussing its terms by comparing that defendant's device therewith, element by element, used the word "auxiliary" in connection with the added valve device, and the word "independent" in defining its location and operation relatively to the "main" valve. After doing so he quotes the second claim, and says "the discussion of the first claim applies equally to this one. In the first claim actuation by the piston of the triple-valve was made an element. In this claim (the second) the inventor more closely limits the mode of such actuation. It is to be by a further traverse of that piston," etc.

He thus takes a view of that claim entirely antagonistic to that of Judge Morris, because it is evident that he considers claim 2 *more limited in its scope* than claim 1; and equally so that he perceives the necessity of including in claim 2, with the triple-valve, "an auxiliary-valve," and impliedly a port and passage governed thereby leading *directly* to the brake-cylinder; and that he found this combination in the New York defendant's device, because, he says—

"It has the main air-pipe, an auxiliary-reservoir, a brake-cylinder, a triple-valve, and an *auxiliary-valve* device, *independent of the main-valve*, for admitting air in the application of the brake *directly* from the main air-pipe to the brake-cylinder. The means for actuating the auxiliary-valve device is stated in the claim to be the piston of the triple-valve and the way in which it acts, as shown in the patent, is by direct impingement upon the stem of the auxiliary-valve device."

(The italics are not in the opinion).

There can be no doubt that Judge Lacombe was right, both in his view of claim 2 and of the infringement of that claim by the defendants in the New York case; and if so, there is equal certainty that Judge Morris was wrong on both these questions in the case at bar, and was properly reversed.

Can any one entertain for an instant a reasonable doubt that Judge Lacombe thought the second claim was not inclusive of an "auxiliary" valve, "independent" of the main valve? It cannot be so pretended with any reasonable hope of belief that he entertained any such view of claim 2 as did Judge Morris, or that he entertained any view thereof substantially different from that adopted by the Circuit Court of Appeals for the Fourth Circuit in the case at bar.

Corroborative evidence of this is furnished by the diagram of the device of the defendant in the case decided by Judge Lacombe, which diagram is annexed to and forms a part of the opinion of the Court of Appeals in the case at bar. (Page 883.)

In his injunction opinion, Judge Lacombe, in reference to the previous decisions in the New York suits, states:

"In these opinions it is held that the two patents, 360,070 and 376,837 disclosed, the one the emergency-valve (auxiliary-valve), the other the supplemental piston or special motor, which, *so far as the art has now*

"progressed appear to be *both* essential to the structure
"of the successful quick-action air-brake."

In expressing this opinion Judge Lacombe correctly deems the "auxiliary-valve" 41, of patent 360,070, and the supplemental piston of patent 376,837, as being "*both essential* to the structure of a successful quick-action air brake" as used in the Westinghouse system. He also says, incorrectly however, that these devices illustrate "the art as far as it has now progressed." Evidently the learned Judge had no knowledge of the later patents issued to Boyden where a new departure is made in the art, and wherein (see Boyden Patent No. 481,131, page 805, fourth paragraph) is disclosed the fact that a triple-valve "*per se* without auxiliary or supplemental-valve devices" and "*a single-valve*—the main valve of the triple proper—is made to perform the office of opening communication to the brake-cylinder from both the train-pipe and the auxiliary-reservoir in the quick application of the brakes for emergency stops."

Judge Lacombe had before him the question as to whether or not a brake mechanism employing alleged *different mechanical means* for opening an "*auxiliary valve*" which governed an *independent* port and passage to the brake-cylinder is an infringement of both the aforesaid Westinghouse patents?

This court has before it a very different question, to wit: whether or not in a triple-valve device an old *main* valve (22) of the triple, which continues as formerly, to perform the old *main* valve function of admitting auxiliary-reservoir air to the brake-cylinder to set the brakes, is now any the less the *main* valve of the "triple," and any the less the same valve that it always was, because it now also performs an added function, namely, admitting train-pipe air direct to the brake-cylinder through the *triple-valve chamber*, and without the use or employment of an independent or separate additional passage-way to the brake-cylinder? In answering this question it must be borne in mind that Mr. Boyden gave the old triple-valve the new capacity to do a *double* duty, or to perform the added function without an auxiliary-valve, and without any additional port or passage-way, by adding his own most ingenious discovery of the effect of *momentary differential pressures* in the triple-valve chambers, applied and accomplished by inserting the

partition or ring 9, with a passage B, to separate or divide the triple-valve chamber C from the piston-chamber D, and thus deliver train-pipe air, when desired, through the triple-valve chamber itself, direct to the brake-cylinder, the main valve of the triple being the governing means for admitting both reservoir air and train-pipe air to the brake-cylinder, instead of separate valves and passages, as in the plaintiffs, for effecting or governing those two distinct functions.

If, therefore, we accept Judge Lacombe's construction of claim 2 as the standard by which to determine whether or not the *Boyden* brake is or is not identical in principle of construction and operation with the Westinghouse device of the patent in suit, no one can entertain any reasonable doubt that the decision of the issue of infringement must necessarily be in favor of defendants in case at bar.

There was no denial on the part of the defendants in the last New York suit, that they used an "auxiliary-valve" and an independent passageway *to admit train-pipe air direct to the brake-cylinder*, their contention being that complainants' patents are only for specific means for actuating the emergency or "auxiliary valve" to control such passageway, and that they (the New York defendants) did not use the said *specific means*, and therefore did not infringe.

As to this the New York Court said, in effect: "The slightly different means which those defendants employed to actuate their '*auxiliary-valve device*' is within the doctrine of equivalents." And the Court was undoubtedly right in that.

But in the case at bar the issue is wholly different. The defendants herein show that in *their* structure, train-pipe air is admitted to the brake-cylinder by the "triple-valve" *per se, without the aid of a separate and independent port and passage, and without an "auxiliary-valve" or any valve other than the old main-valve of the triple; and that this result is accomplished by defendants by wholly novel means, confessedly new with Boyden*, and so (three times) adjudged to be (1) by the Patent Office, (2) by the Circuit Court and (3) by the Court of Appeals.

In the New York case, Judge Lacombe discusses the file and contents of patent 360,070, and says:

"There is nothing in the file wrapper or contents (360,070) to show that the Patent Office required, or that the inventor agreed to abandon, *what was the great feature of his invention, the emergency valve*, (the 'auxiliary valve' 41) or to give up whatever range of equivalents his patent might, as modified, fairly cover."

Of course not, and *we* don't contend that there is anything in the file wrapper and contents to show that the Patent Office required the inventor to give up what was "the great feature of his invention—the emergency valve," namely, the *auxiliary valve* 41, and the port and passage 46 governed thereby, to admit train-pipe pressure *direct* to the brake-cylinder. The file wrapper, however, *does* show clearly that the Patent Office *did* require him to give up the original and erased first claim for a triple-valve, "*provided with a device*" (generically) for admitting air directly from the main air-pipe to the brake-cylinder, and in cancelling said claim he cancelled the statement calling for an imaginary *integral* structure for that purpose. Therefore patent 360,070 *does not cover that*, and to confirm this act his letter accompanying the cancellation defines the novelty of his invention as residing in the *combination* with a *known triple-valve* of an "additional" and *auxiliary valve* adapted to be *actuated* by the piston of the triple to govern an *independent* port and passage leading *directly* to the brake-cylinder.

Mr. Westinghouse undoubtedly made a new invention, which, in the improved form shown in his later patent, is valuable and deserving of great commendation, and his patent therefor should be given a liberal construction, limited only by the necessary as well as by the self-imposed limitations clearly expressed in the patent itself. Judge Lacombe in defining it and construing the claims has imposed no greater limitations than we contend for, viz., that the new and "additional members" in the combination, no matter what their specific character, shall be physically and functionally "auxiliary" to the triple-valve proper (the old element which in the new Westinghouse combination is used without change and precisely as it was before) and that as respects the auxiliary or emergency valve it shall be "independent of the main-valve," and that the passageway governed thereby shall lead "*directly* from the main-air pipe to the brake-cylinder" (to quote the words of claim 2.)

Whether the patent in question be a pioneer or a mere improvement patent, cannot in either case warrant the application of any rule of construction which disregards these fundamental principles governing the interpretation of patent claims. Neither of the late cases of *Miller vs. Eagle Co.*, 151 U. S., nor *Morley vs. Lancaster*, 129 U. S., afford the slightest ground for so broadly interpreting the claims of a patent, whether pioneer or not, to include functional equivalents of mechanisms which, while producing the same result as those of the patent do so by means which are *not* substantially the same as those of the patent, but are so different in principle of construction and operation therefrom as to make their structural features and operative functions wholly repugnant to and irreconcilable with the description of the construction and operation of the patented mechanism as the same is set forth in the specification of the patent in question. In proof of which this Court said, in respect of the Morley machine, that the claims in question of his patent are not for a result or effect, irrespective of the *means* by which the effect is accomplished. "It is open to a subsequent inventor to accomplish the same result, if he can, by substantially different means." (See page 286 of the opinion.)

The Court of Appeals, in the case at bar, also referred to the file-wrapper and contents of the application for the patent 360,070, not as stated in the Plaintiffs' petition for *certiorari*, but properly as corroboratory of its conclusions already found and stated, from the patent itself, that the "additional" parts constituting the novel elements in the combination patented were (a) an "auxiliary"-valve, "independent" of the main valve, and (b) a "separate" passage way governed thereby, leading "directly" from the train-pipe to the brake-cylinder. And in this connection it is to be noted that the word "directly" appears in the 2d claim.

The application for patent 360,070, as filed by Mr. Westinghouse, contained the following as the original first claim (p. 714):

"1. In a brake mechanism the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder and a triple valve *provided with a device* for admitting air directly from the main air-pipe to the brake-cylinder; substantially as described." (The italics are ours.)

On objections by the Patent Office, including *inter alia* the citation of a prior patent, Mr. Westinghouse erased this claim.

As a logical conclusion of fact it cannot be open to doubt that the construction he is now asking for claim 2, *as against this defendant*, is exactly the generic but imaginary construction of mechanism which he sought to cover by said erased claim; and as a logical deduction of law from a long line of authorities in this Court, it is equally certain that he is estopped from so doing. Knapp vs. Morse, 150 U. S., 221; Corbin Lock Co. vs. Eagle Lock Co., 150 U. S., 38, and cases cited therein.

The decision in Reece vs. Sewing Machine Co., 61 Fed. Rep., 958, affords no countenance for any qualification of this salutary rule; besides, the facts in that case have no parallel with those in the case at bar. The decision in Reece's case turned on the fact that the narrowing amendment ought not to have been required and was inadvertantly made; but the decision distinctly recognizes the soundness of the previous authorities, which hold the patentee to the usual legal effect of such amendments in matters of substance, if it shall appear that the same were understandingly or voluntarily made, or were in fact necessary in view of the prior references cited, or of the state of the art generally. Indeed, the court refers to and quotes with approval its previous ruling in Ball and Socket Fastener Co. vs. Ball Glove Fastener Co., 58 Fed. Rep., 818, in the following words:

"The rule touching the effect of such amendments has been several times laid down by the Supreme Court in patent cases, although it is only a peculiar application of the general principles of law relative to the interpretation of instruments. In the case at bar, the amendments relate to the very pith and marrow of the alleged improvement, touch directly the question of novelty, and were understandingly and deliberately assented to; so that the rule of interpretation referred to undoubtedly applied."

The contents of the file of the application, in the rejection and erasure of the original first claim, and the explanatory letter of the applicant to the Patent Office, clearly show that the invention patented does *not* consist of some improvement in and of the triple-valve itself, nor in a triple-valve provided with "a device" for admitting air directly from the train-pipe to the brake-cylinder (the erased claim), but consists of a combi-

nation of the old triple-valve with some *added* and *auxiliary* means, physically and functionally independent therefrom, but so arranged relatively thereto as to be brought into action on the same old extreme traverse of the triple-valve piston, and operating to produce its own specific result in the performance of the aggregate results by the combined mechanisms. This is what the applicant, Westinghouse, in his letter to the Patent Office after the rejection of his original first claim meant, when he said he believed "such combination" to be novel. No one disputed that so far as this record discloses. What *is* disputed is his *present* contention that his 2d claim shall be now construed as for means which are *not* "auxiliary" to and *not* "independent" of the triple-valve as previously employed, and for means which are integral with and a part of the triple-valve, comprising modifications in the triple-valve chamber and a utilization of the main-valve, by force of such changes, to perform a double function—*i. e.*, its old triple-valve function and a new one which, but for such changes, it would be incapable of performing. These latter sentences describe this defendant's machine; a device comprising mechanisms never dreamed of by Mr. Westinghouse before he saw Boyden's machine, and which are so radically different in principle of construction and operation from his own, that by no stretch of imagination, based on anything found in patent 360,070, could they have been contemplated by the Patent Office officials to be within any of the claims of Westinghouse's patent as allowed to him.

It is respectfully submitted that there is no error in the decree sought to be reviewed, and that it should be affirmed.

CROSS-APPEAL.

THE SECOND CLAIM OF THE WESTINGHOUSE PATENT NO. 360,070 IS INVALID AND VOID.

The claim reads as follows:

"2. In a brake mechanism the combination of a main
"air-pipe, an auxiliary-reservoir, a brake-cylinder, and a
"triple-valve having a piston whose preliminary traverse
"admits air from the auxiliary-reservoir to the brake-
"cylinder, and which by a further traverse admits air
"directly from the main air-pipe to the brake-cylinder;
"substantially as set forth."

This claim is invalid and void—

(a) Because all its expressed elements were old and were combined in the same way in prior patented structures.

(b) Because, if the claim is read as for a combination other than of its expressed elements, it is a claim for a result.

(c) Because, if so read, it is a claim not only for a result, but for a result that is not useful.

THE COMBINATION OF THE EXPRESSED ELEMENTS OF THE
CLAIM WAS OLD.

The expressed elements of the claim are :

- (1) A main air-pipe.
- (2) An auxiliary-reservoir.
- (3) A brake-cylinder, and
- (4) A triple-valve whose piston has a "preliminary traverse" and also a "further traverse." These elements so combined are all found in the prior Westinghouse patent No. 220,556.

This is easily verified. On looking at Fig. 1 of patent 220,556 (p. 762) there will be found a passage P, P¹ leading from train-pipe to the piston-chamber B¹; a piston G in the piston-chamber constituting the valve for controlling the flow of air through port *a* (shown in Fig. 4) to the passage R leading to auxiliary-reservoir; a main slide-valve H having a passage *s* for controlling communication between the passage C leading from brake-cylinder to the exhaust port E, which opens to the atmosphere; the graduating-valve *e*¹ having its seat in the passage in the main slide-valve H for controlling the flow of air from auxiliary-reservoir to brake-cylinder through port *s*¹ in the slide-valve H and passage C; and the slide-valve H, as a whole, operating, when the piston G makes its further or full traverse under a considerable reduction of pressure in the train-pipe, to entirely uncover passage C and permit auxiliary-air to pass through passage C to the brake-cylinder, to secure the maximum braking effect in an emergency application of the brakes, or when the train-pipe is burst or ruptured.

The "preliminary traverse" of the piston of the device of this patent 220,556 occurs when ordinary service stops are made, while the "further traverse" is made in an emergency application of the brakes by the opening wide of the engineer's valve on the locomotive or upon an automatic application of the

brakes by the bursting of the train-pipe or the parting of the train into two sections.

The importance of the "further" or *full* traverse of the piston is dwelt upon in the Westinghouse catalogue issued in 1886, (page 594), and is testified to by Mr. Newbury, Complainant's expert, (page 263, X. Q. 358; pages 263-4, X. Q. 360-3;) by Mr. H. H. Westinghouse, (pages 270-1, Q. 378, page 328, X. Q. 565;) by Complainant's witness Kidder, a practical locomotive engineer, (page 432, X. Q. 781;) by Complainant's witness, Nellis, another practical locomotive engineer, (page 438, X. Q. 807.)

Limited, then, to a combination of its expressed elements the second claim is anticipated by said prior Westinghouse patent No. 220,556.

IF THE CLAIM IS READ AS FOR A COMBINATION OTHER THAN ITS EXPRESSED ELEMENTS, IT IS A CLAIM FOR A RESULT.

If the claim be not thus limited to the combination of its expressed elements, but, because of its inclusion of the phrase, "and which by a further traverse admits air directly from the main air pipe to the brake-cylinder, substantially as set forth," it is attempted to be extended to cover anything more than the expressed elements plus the "additional" elements described as such in the body of the specification and embodied in the first and fourth claims, it is invalid and void as being a claim for a mere result.

Patents for machines are not granted for an idea, an abstraction or a result, but for concrete, tangible mechanical elements, or combinations of mechanical elements.

In *Burr vs. Duryear*, 1 Wall., 570, this Court, speaking through Mr. Justice Grier, said:

"The Patent Act grants a monopoly to any one who
"may have discovered or invented any new and useful
"art, machine, manufacture or composition of matter.

"That the invention of Wells comes within the category of a '*machine*' cannot be disputed. The law
"requires that the specification 'should set forth the principle and the several modes in which he has contemplated the application of that principle, or character by
"which it may be distinguished from other inventions,
"and shall particularly point out the part, improvement,

“or combination which he claims as his own invention or ‘discovery.’ We find here no authority to grant a patent for a ‘principle’ or a mode of operation, or an *idea*, or ‘any other abstraction. A machine is a concrete thing, ‘consisting of parts, or of certain devices and combination of devices. The principle of a machine is properly ‘defined to be its mode of operation, or that peculiar combination of devices which distinguish it from other machines. A machine is not a principle or an idea. ‘The use of ill defined abstract phraseology is the frequent source of error. It requires no great ingenuity to mystify a subject by the use of abstract terms of ‘indefinite or equivocal meaning. Because the law ‘requires a patentee to explain the mode of operation of ‘his peculiar machine which distinguishes it from others, ‘it does not authorize a patent for a ‘mode of operation ‘as exhibited in the machine,’ much less can any inference be drawn from the statute, that an inventor who ‘has made an improvement in a machine, and thus effects ‘the desired result in a better or cheaper manner than ‘before, can include all previous inventions and have a ‘claim to the whole art, discovery, or machine which he ‘has improved. All others have an equal right to make ‘improved machines, provided they do not embody the ‘same, or substantially the same devices, or combination ‘of devices, which constitute the peculiar characteristics ‘of the previous invention.”

In *Fuller vs. Yentzer*, 94 U.S. 288, this Court speaking through Mr. Justice Clifford, also said:

“Patents for a machine will not be sustained if the ‘claim is for a result, the established rule being that the ‘invention, if any, within the meaning of the Patent ‘Act, consists in the means or apparatus by which the ‘result is obtained, and not merely in the mode of operation independent of the mechanical devices employed ; ‘nor will a patent be held valid for a principle or for an ‘idea, or any other mere abstraction.”

Now, I submit, no candid mind can read the second claim of the patent in suit without concluding that it embodies an

attempt to claim a result. To say that the "further traverse" of the piston of the triple-valve "admits air directly from the main air pipe to the brake cylinder" is simply to state the result accomplished when such movement of the piston takes place. It does not tell us *how* that result is accomplished, *by what means* it is accomplished; but simply that it is accomplished. The claim is in effect for the *doing* of the thing without reference to the way of or *means* for doing it.

The case cannot be distinguished in principle from the leading case of O'Reilly vs. Morse, 15 How., 62. In that great case the eighth claim of the Morse patent, which was held invalid, read as follows:

"8th. I do not propose to limit myself to the specific machinery or parts of machinery described in the foregoing specification and claims; the essence of my invention being the use of the motive power of the electric or galvanic current, which I call electro magnetism, however developed for marking or printing intelligible characters, signs, or letters, at any distance, being a new application of that power of which I claim to be the first inventor or discoverer."

Chief Justice Taney, in delivering the opinion of this Court, said, (page 112:)

"It is impossible to misunderstand the extent of this claim. He claims the exclusive right to every improvement where the motive power is the electric or galvanic current, and the result is the marking or printing in intelligible characters, signs, or letters, at a distance. If this claim can be maintained, it matters not by what processes or machinery the result is accomplished. For aught that we now know some future inventor, in the onward march of science, may discover a mode of writing or of printing at a distance by means of the electric or galvanic current, without using any part of the process or combination set forth in the Plaintiff's specification.

"His invention may be less complicated—less liable to get out of order—less expensive in construction, and in its operation, but if it is covered by this patent the

“inventor could not use it, nor the public have the benefit of it without the permission of this patentee.”

Again, page 119:

“The provisions of the Acts of Congress in relation to patents may be summed up in a few words. Whoever discovers that a certain useful result will be produced, in any art, machine, manufacture or composition of matter, by the use of certain means, is entitled to a patent for it; provided he specifies the means he uses in a manner so full and exact that any one skilled in the science to which it appertains can, by using the means he specifies, without any addition to or subtraction from them, produce precisely the result he describes. And if this cannot be done by the means he describes, the patent is void. And if it can be done, then the patent confers on him the exclusive right to use the means he specifies to produce the result or effect he describes, and nothing more. And it makes no difference, in this respect, whether the effect is produced by a chemical agency or combination; or by the application of discoveries or principles in natural philosophy known or unknown before his invention; or by machinery acting altogether upon mechanical principles. In either case he must describe the manner and process as above mentioned, and the end it accomplishes. And any one may lawfully accomplish the same end without infringing the patent, if he uses means substantially different from those described.

“Indeed, if the eighth claim of the patentee can be maintained, there was no necessity for any specification further than to say that he had discovered that, by using the motive power of electro magnetism, he could print intelligible characters at any distance. We presume it will be admitted on all hands that no patent could have issued on such a specification. Yet this claim can derive no aid from the specification filed. It is outside of it, and, the patentee claims, beyond it. And if it stands, it must stand simply on the ground that the broad terms above mentioned were a sufficient descrip-

"tion, and entitled him to a patent in terms equally
 "broad. In our judgment, the Act of Congress cannot be
 "so construed."

To show how applicable the principle of the Morse case is to the one at bar, the *eighth* claim of Morse and the *second* claim of the patent in suit *paraphrased* are here set up in parallel columns for comparison :

MORSE'S VOID EIGHTH
 CLAIM.

"8th. I do not propose to
 "limit myself to the specific
 "machinery or parts of ma-
 "chinery described in the fore-
 "going specification and claims,
 "the essence of my invention
 "being the use of the motive
 "power of the electric or gal-
 "vanic current, which I call
 "electro magnetism, however
 "developed for marking or
 "printing intelligible charac-
 "ters, signs, or letters, at any
 "distance, being a new appli-
 "cation of that power of which
 "I claim to be the first in-
 "ventor or discoverer."

WESTINGHOUSE'S SECOND CLAIM
 PARAPHRASED.

2d. I do not propose to
 limit myself to the specific
 machinery or parts of ma-
 chinery described in the fore-
 going specification and claims,
 the essence of my invention
 being the use of that part of
 the motion of the triple-valve
 piston, which I call the "fur-
 ther traverse," however devel-
 oped for admitting air
 directly from the main air-
 pipe to the brake-cylinder,
 being a new application of
 that piston-motion of which
 I claim to be the first in-
 ventor or discoverer.

This is not an unfair comparison. Morse endeavored to cover the use of the motive power of the electric or galvanic current for printing intelligible characters, signs or letters at any distance without any limitation as to the means to be employed, while Westinghouse, in like manner, attempted to cover the use of the motion of the triple-valve piston to admit air directly from the main air-pipe to the brake-cylinder, irrespective of the kind or character of the means employed for achieving that result. It was the omission of the printing or recording devices by which the result of printing intelligible characters at a distance was accomplished that rendered the eighth claim of

Morse invalid, just as it is the omission of the additional auxiliary-valve device by which the result of admitting train-pipe air directly to the brake-cylinder is effected that renders the second claim of Westinghouse invalid.

Both Morse and Westinghouse tried to appropriate an idea to cover all ways and means of effecting a result, and the condemnatory language of this Court applies to each of them with equal force.

THE RESULT CLAIMED AS A USELESS RESULT.

Not only is this second claim a claim for a mere result, but it is also a claim for a result that is not useful, and, hence, in any view not patentable.

The second claim, like the first claim, refers to the specification by the phrase "substantially as set forth," but nowhere in the specification is it suggested that any brake apparatus had been conceived of by the patentee wherein the result of quick action could be accomplished by the mere admission of train-pipe air alone, "directly from the main air-pipe to the brake-cylinder."

The only apparatus described or hinted at in the patent for accomplishing quick-action is an apparatus in which, upon the full or further traverse of the piston, train-pipe air *and* auxiliary-reservoir air are *both* admitted, substantially simultaneously, into the brake-cylinder.

The claim, therefore, not only states a result, instead of competent mechanism for accomplishing a result, but it states a result that the patentee had not indicated might be accomplished, and a result that, according to what is stated in the specification and in the evidence of all the experts in the case, is entirely lacking in utility.

If it is conceded, as it must be, that the additional function or result of admitting auxiliary-reservoir pressure as well as train-pipe pressure to the brake-cylinder during the further traverse of the piston *is necessary*, but is contended that the Court may read into this second claim such additional function or result, the complete answer is, that, to do so, would make the second claim identical with the third claim, that is not in

issue and that is not alleged to be infringed, which reads as follows :

"3. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder and effects a *second admission of air from the auxiliary reservoir to the brake-cylinder*; substantially as set forth."

This third claim, like the second claim, is clearly void because embodying an attempt to claim a result, but it at least has the merit of stating a full and useful result, which the second claim has not.

THE PATENTEE, NOT THE PUBLIC, IS RESPONSIBLE FOR THE WORDING OF THE CLAIM AND HE AND NOT THE PUBLIC MUST SUFFER IF IT IS DEFECTIVE.

Claims are required by the Statute. They are necessary in order that the metes and bounds of a patent may be defined with clearness, that the public may know what is protected and what is free.

This case develops no equities requiring a departure from the ordinary rules governing the treatment of patents and patentees.

Westinghouse was an old inventor, a veteran patentee, of ample means and favored with the aid of experienced counsel and solicitors. Everything done in obtaining his patent was with eyes wide open and under the fullest advice. In pressing the second claim he simply overreached as did Morse with his eighth claim.

If the second claim were the only claim of the patent the Court might possibly, in their anxiety to prevent an entire loss of the invention, construe the claim, by narrowing it, so as to include, under the terms "*substantially as set forth*," the additional auxiliary-valve device described and shown in the specification and drawings. This would have been going to the

very verge of liberality. But no such exigency, no such necessity exists. There are, as we have seen, other claims in the patent which fully cover the structure which the patentee has actually shown and described, and it would be a vain thing, as well as repugnant to all settled rules of construction, to interpret the second claim, for the mere purpose of saving it, *to mean the same thing as some other claim.*

Who should suffer from this faulty claim—the patentee, who drew it, or the Defendants, who had no hand in its preparation?

Complainant admits that it is defective, but asks the Court to construe into it *just enough* to hold the Defendant's device, which does not embody the elements of the other claims, but *not enough* to make it open to the objection of being the same as the other claims.

This Court will not adopt any such elastic construction of plain language. They will rather reiterate what they said in *White vs. Dunbar*, 119 U. S. 47, where, speaking through Mr. Justice Bradley, they said:

“Some persons seem to suppose that a claim in a patent is like a nose of wax, which may be turned and twisted in any direction, by merely referring to the specification, so as to make it include something more than or something different from, what its words express. The context may, undoubtedly, be resorted to, and often is resorted to for the purpose of better understanding the meaning of the claim; but not for the purpose of changing it, and making it different from what it is.”

“The claim is a statutory requirement, prescribed for the very purpose of making the patentee define precisely what his invention is; and it is unjust to the public, as well as an evasion of the law, to construe it in a manner different from the plain import of its terms.”

CROSS-APPEAL.

NOTES OF RE-ARGUMENT,

BY

MR. FENTON,

ON BEHALF OF THE BOYDEN BRAKE COMPANY.

The record in this case discloses that the appellate decree complained of adjudicated a single issue of fact. The patent in suit was not attacked for want of novelty, nor is it alleged to be invalid in any respect under proper construction of its claims, nor is there any valid ground for dispute in that regard except as to the *second* claim. There is no REAL controversy involved in this case except the single question of whether the two machines of the parties appellant and appellee (which are admittedly widely different in *mechanical* construction), are or are not identical in *principle* of construction and operation,

or whether (as we contend and as both courts below have adjudged) they are constructed and operate on radically different principles. Of course the interpretation of the disputed claim 2 is necessarily incidently involved under such an issue of fact, but that is true of such an issue in every patent cause.

An Analysis of the Plaintiffs' Assignments of Error.

The assignments of error set forth on pages 2 to 4 of the Westinghouse principal brief, are seven in number. Not a single one of them except the 6th and 7th (which are practically the same and relate to the findings of the Court under the issue of infringement), raise any question decisive of the single and only issue involved in the cause. Of the remaining assignments of error, the *first* sets up an alleged conflict of decision between the appellate tribunals in the Second and Fourth Circuits; the *second* alleges that the Court of Appeals adjudicated the second claim of the patent in suit to be invalid; the *third* alleges error in giving improper effect to the defendants' patent as a piece of evidence; the *fourth* alleges error in law in the effect given to the term "substantially as set forth" in construing the claims; and the *fifth* avers error in the effect given to the file and contents of the application for the patent in suit.

It is proposed to direct this argument principally to a brief review of the errors assigned and to show their immateriality, leaving to my colleague to present a more extended argument differentiating in detail the machines of the parties, showing also the evolution of each of them and demonstrating their radical differences in principle.

1. As to the alleged conflict of decision between the appellate tribunals in the Second and Fourth Circuits in respect of the validity of claim 2. Of course this allegation presupposes that they both passed upon the same question arising upon the same or analogous premises. They did nothing of the kind.

Neither of them passed upon an abstract question. Neither of them construed claim 2 regardless of the character of the alleged infringing device which it was charged infringed it. The two tribunals had before them, respectively, two totally different structures alleged to infringe. The defendants' device (N. Y. Air Brake Co.) before the Court in the Second Circuit, was an obvious infringement; and it was equally obvious that the defendants' (Boyden) device before the appellate tribunal in the Fourth Circuit was not. So much was this the case, that the defendants in the Fourth Circuit asked the Court to apply the interpretation of the 2d claim as adjudicated in the Second Circuit. There is not necessarily any conflict of decision as respects the validity and scope of a patent claim, merely because as between two alleged infringing devices, one is held to infringe the claim and the other is not.

This alleged conflict of decision can be disposed of very briefly. It has been fully discussed in my printed brief heretofore filed (see pages 21 to 26), to which special reference is requested. It is not proposed now to take up time by discussing the propriety or correctness of dicta appearing in the opinion of either Court. Faults in that respect may doubtless be found in both. We are to consider only the correctness of the matter *adjudicated*; not mere isolated inartificial expressions occurring in the opinions of the respective Courts. Whether or not there may be paragraphs which, considered apart from the whole, are open to criticism, is not of the least importance *in the decision of this case in this court*, if we can gather from the whole opinion of the Appellate Court below that it *adjudicated the single issue* in the case *correctly*. This appeal is taken to review the *decree* of the Court below, not mere dicta in its *opinion*.

If, however, we look to the opinion to ascertain on what conclusions the decree is founded, a single reference will be sufficient to demonstrate beyond any doubt that the decree was right. The Court of Appeals, whether it meant to hold claim 2

invalid under the doctrine of *Morse vs. O'Reilly*, certainly did not rest its adjudication thereon, but disposed of the case on a different ground, because, after discussing claim 2, it gave effect to it as a valid claim by stating in substance that its concluding words, "substantially as set forth," implied the presence of the elements necessary to perform the function recited in the claim, but did not confine the claim to the particular construction of these elements. These two propositions appear very clearly from the opinion (see R., p. 878, folios 1416 and 1417), in which the Court said:

Folio 1416—

"These words ('substantially as described') limit the "general terms of the specification which set out the "*function* * * * to his own means or their *mechanical equivalent* for performing the function."

Folio 1417—

"The question at bar is whether Boyden's (quick-action improvement on the triple-valve of the old patent, 220,556) "is the mechanical equivalent of Westinghouse's (quick-action improvement on the triple-valve of his old patent, 220,556). * * * They seem to us to differ "as widely from each other as two devices for accomplishing the same result can well differ." (R., p. 880, l. 30.)

Thus showing that the Court of Appeals, notwithstanding what it said in just criticism of the form of the claim, actually rested its decision upon two propositions: 1st. That the "*question at bar*" was whether or not the machines of Boyden and Westinghouse were the "mechanical equivalents" of each other; and, 2d, Finding, on comparison, that they were radically different from each other.

If these two quotations do not show conclusively that the Appellate Court rested its decision solely on the radical differences in principle between the two machines, there is no force in English words.

There was no effort made or argument advanced by the Boyden Brake Company in the Court of Appeals to dispute, qualify

or limit the scope or effect of the decisions in the Second Circuit as *res judicata* on the construction of the claims; but, on the contrary, we relied upon and urged upon the Appellate Court in the Fourth Circuit that the construction and interpretation of the plaintiffs' patent, and especially of claim 2 thereof, by Judge Lacombe (65 Fed. Rep., 99, affirmed on appeal), was correct; and that, if accepted as correct and followed by the Court of Appeals in the Fourth Circuit, it required that the latter tribunal should reverse the decree entered by the Circuit Court in the case at bar, which construed the claim 2 aforesaid very differently and inconsistently with the construction given to it in the Second Circuit; and this I shall endeavor to clearly demonstrate in its appropriate place in this argument.

The radical differences between the devices of the respective defendants in the two circuits is clearly pointed out in the opinion of Judge Hughes.

On the subject of the effect of the decision of Judge Lacombe, alleged by the Westinghouse counsel to be *res judicata* on the same question before the appellate tribunal in the 4th circuit, the learned Judge in the latter court stated the difference between the two questions before the two respective courts in the following words (R., p. 883):

"Here it is contended (by plaintiffs) that the mere use of the extreme traverse of the triple-valve piston to effect the same *functional* result which was effected by Westinghouse in 360,070, constitutes an infringement, irrespectively of the additional means employed. There it was ruled that the use of the extreme traverse and of an additional machine attached to the original 220,556, which was structurally and *mechanically* equivalent to 360,070, was an infringement of the latter patent. The cases are different, and not on all fours."

The learned Judge (Hughes) was entirely correct in that statement. The defendant's machine before the New York court (as shown opp. R., p. 883), contained an "auxiliary" valve and a

segregated passageway controlled by it; and Judge Lacombe found infringement (see 65 Fed., p. 101), because of the presence in **that** defendant's machine of a "triple-valve" **and** an auxiliary-valve device, independent of the "main valve"; adding in substance (page 102 of report) that claim 1, which includes these elements, does not differ from claim 2 (here under discussion), except that the latter is even more limited—*i. e.*, that "it is to be by a further traverse of the piston." And this is the sole distinction which differentiates the two claims. Obviously there is no conflict of decision between the two courts on the same *question of the construction of claim 2*. The pretence that Judge Hughes' remarks on the invalidity of functional or result claims, constitutes such a conflict, is without foundation, when it is seen that the "question at bar," as stated by the court in the 4th circuit, and on the adjudication of which the decree of reversal was rested, was whether or not, under the same interpretation of the claim 2 as stated by Judge Lacombe, the machines of the parties in the case at bar were or were not *mechanical* equivalents; and he held, and properly held, that they were not. (See insert illustrating the three structures.)

2. As to the alleged errors set forth in the third assignment of error, what matters it, whether the learned Judge who wrote the opinion of the Appellate Court in the Fourth Circuit was right or wrong in saying that "the Patent Office employs the best experts in mechanics which it can secure in this and other countries." Is the time of this Court to be wasted in deciding that moot question? If it has any materiality at all it is presumably true, no matter what the actual fact may be, as the statute requires the Commissioner to appoint an examining corps skilled in the arts and does *not* require him to confine his appointments to citizens of the United States. The second branch of this assignment is without merit, for the language criticised is a paraphrase of a sentence correctly

used by so eminent a patent jurist as the late Justice Bradley, in *Burns vs. Meyres* 100 U. S., 671 (672). The third and fourth branches of this assignment of error are not well founded because it is too well settled in this Court to be open to dispute at this late day, that the action of the Patent office in awarding a patent to the defendant is evidence of some considerable weight that the thing described and claimed therein is not identical with the subject matter of a prior patent, especially where such prior patent was called to the attention of the Commissioner and actually considered by him in passing upon the novelty and patentability of the later device. *Miller vs. Eagle Co.* 151, U. S. 186 (208). The reason of this rule of evidence is clearly stated in *Corning vs. Burden*, 15 Howard 252.

3. As to the fourth assignment of error, it is respectfully submitted that the Court below was not only substantially correct, but absolutely accurate in its definition of the term "substantially as described."

The Court said (see R., p. 878, folio 1416); "These words limit the general terms of the specification which set out the *function* performed by the invention and confine the inventor's rights to his own *means*, or their *mechanical equivalent* of performing the function." No possible objection can be successfully made to this strictly accurate and broad definition.

4. The matter of the fifth assignment of error relating to the effect of the file wrapper and contents of the application for the patent in suit, in the interpretation of the claim, will be discussed more fully hereafter in the brief argument which I shall make on the construction of the claims.

In approaching the consideration of this single issue of non-infringement, we may first refer to three potential propositions, none of which can be successfully disputed:—

1. The two machines of the parties litigant are obviously and admittedly as widely different in mechanical construction as two things to produce the same result can possibly be.

2. The fact that two devices produce and are intended to produce the same result, does not establish that they are alike in principle, nor is it even *prima facie* evidence thereof.

3. That the burden of sustaining the affirmative of the issue of infringement beyond any reasonable doubt is upon the plaintiff, and that this burden is not discharged merely by showing that two machines were designed to produce or do in fact produce the same result, if upon the plaintiffs' proofs comparing the two mechanical devices structurally, the question of identity or non-identity in principle of construction and operation is left open or qualified by the least conjecture or doubt.

The Defendants' Patents and Their Effect as Evidence Under the Issue of Infringement.

The radical differences in principle between the plaintiffs and defendants machines, are fully described in three patents to defendants, differentiating the device from the plaintiffs invention of the patent in suit, and containing grants to defendants of claims of such breadth and scope as to be utterly inconsistent with the theory that the defendants' machine is at all alike to the plaintiffs in principle.

The record contains evidence showing the evolution of the defendants' device which is alleged to infringe. The device, as admitted, is the structure described in the patents granted to Boyden August 16, 1892, Nos. 481,134, 481,135 and 481,136. Application was filed in the Patent Office for one of these September 30, 1889, before this suit was brought.

They all retain the essential underlying principle of the previous Boyden 1883 patent (R., p. 498) in that they provide means to convey *train-pipe air* to the brake-cylinder *through the triple-valve-chamber* (and not through any separate and independent passageway) the said machines retaining all the usual parts and functions of a triple-valve per se. The means (patented by Nos. 481,134, etc.), for performing the additional function

referred to are shown in a diagram opposite page 14 of my former brief, and so fully described, discussed and compared with the complainants' device that it is not necessary now to reiterate.

The proposition now to be discussed is the legal effect of this differentiation, which is found expressed on the face of these later Boyden patents, and the broad claims allowed for this distinctively different and novel device.

The reason for the usual exclusion of such evidence is founded on the theory that a posterior patent could not justify an infringement of a prior one *for the same invention*.

The posterior patents are not set up in this case as being for the *same invention* as the plaintiffs', but as evidence that the defendants' device, described and claimed in it, *differs essentially, quoad* the part or improvement claimed in the prior patent, from the machine of such prior patent.

These patents show by their descriptive matter and by their claims the *quasi* judicial finding of the Patent Office, that the device described and claimed in the later patents to defendants is not the mechanical equivalent for, or an improvement on, the device described in the earlier patent of complainants, and that the devices of the two patents are for *distinct and different* inventions, constructed and operating on different principles, though both producing the same result.

The question is presented in the case at bar under the third assignment of error and the argument on it in the Westinghouse brief (see page 3 pages 83 to 91). In the case at bar the Circuit Court practically refused to give any weight whatever to these patents as evidence for the purpose for which they were introduced, on the ground that the Patent Office was "unassisted by testimony as to the state of the art at the date of the Westinghouse patent, and without testimony as to the scope of the Westinghouse quick-action invention." (See Record, page 852.)

This is a new doctrine without precedent. It is no part of the duty of the Patent Office to take *testimony* as to the state

of the art or as to the scope and importance of an invention. When an application such as Boyden's was filed it was the duty of the Commissioner to consider the patent here in suit as part of the prior art, to determine whether or not they were for the same invention in whole or in part, or whether they were for different inventions constructed and operating on different principles.

Presumably the Commissioner did his duty, and the record in this case shows that he did so in fact. The Court of Appeals, however, correctly gave due and proper weight to the defendants' patents as evidence of non-identity. That Court did not decide that the Patent Office had passed upon the question of "infringement" in the narrow sense pretended in the Westinghouse brief, but distinctly held that the ruling of the Patent Office in granting the defendants' patents was prima facie evidence of non-identity, and distinctly said also that this ruling was not conclusive, but was entitled, however, to great respect and to have due weight given to it. This ruling was absolutely correct, as will appear by reference to *Miller vs. Eagle Co.*, 151 U. S., 208, which affirms Mr. Justice Grier in *Corning vs. Burden*, 15 How., 252. The latter case discusses this question so fully that we ask special attention to it. Mr. Justice Grier calls our attention to the fact that since the patent act requiring examinations of applications as to novelty, the grant of a patent to the plaintiffs is prima facie evidence of novelty. The learned Judge said that in cases of doubt the defendant is equally entitled to the same presumptions arising from the grant of a patent to him. Practically applying the rule in *Brooks vs. Bicknell*, 2 McLean, 432, Justice McLean said that under the issue of infringement, where the evidence is evenly balanced, the burden of proof being on the plaintiff, if the defendant has a patent for the device used by him which is not a mere improvement upon the plaintiff's, the defendant's patent is sufficient to turn the scale in his favor, under the issue of

infringement, or even to resolve a *doubt* in the same way (if there be a doubt) under this issue. (See also *New Mfg. Co. vs. Superior Co.*, 56 Fed., R., p. 152.)

An examination of the patents granted to Mr. Boyden for this ingenious invention, Nos. 481,134, 481,135 and 481,136, will show that he therein fully set forth the principle of his invention and clearly distinguished it from that of the patent in suit. We call attention especially to the following extract from the specification (R., p. 805, l. 3, of his patent, No. 481,134), which was filed in the Patent Office *before* this suit was brought (the italics being our own), viz:

"Efforts have been made heretofore to combine with a
 "triple-valve certain *additional* mechanism by which
 "train-pipe air could be introduced directly into the
 "brake-cylinder in effecting the application of the brakes
 "for emergency stops; but in every such instance a *sup-*
 "*plemental passage* or passages together with a *supple-*
 "*mental* or *auxiliary* valve, has had to be employed in
 "connection with the triple-valve proper, in order that
 "the ordinary functions of the triple-valve might be pre-
 "served and the additional function of introducing train-
 "pipe air into the brake-cylinder for emergency stops
 "be combined therewith." "An example of the class of
 "valves referred to in the last preceding paragraph which
 "employ an auxiliary-valve, combined with an ordinary
 "triple-valve, is shown in United States patent to George
 "Westinghouse, Jr, dated March 29, 1887, No. 369,070."

"It will be seen that my present invention for introduc-
 "ing train-pipe air into the brake-cylinder for emergency
 "stops differs essentially from the device shown in the
 "said Patent No. 369,070, because I have provided a *new*
 "*principle of construction* and a *new mode of operation*
 "by use of which the desired result aforesaid may be pro-
 "duced *without the aid of the auxiliary-valve heretofore*
 "*required for the purpose.*"

It will be seen that the above extracts fully distinguish the Boyden invention from that of the patent in suit, and, by

granting the patents to Boyden containing these statements, and broad claims based upon the novel device thus differentiated, the disinterested and experienced experts in the examining corps of the Patent Office signified their full recognition of the facts stated, which accord in all respects with the position taken in this suit by the defendants' experts.

A casual glance at claim 1 (R. p. 806) of defendants' patent 481,134 to Boyden, will disclose, in a condensed statement therein, how it differs in principle and operation from the patent in suit. The Patent Office was obliged to consider the question of novelty, in a patentable sense, of Boyden's device as compared with that of the patent in suit. Its decision in favor of Boyden, by the grant to him of these patents, raises a strong *legal* presumption of *non-identity* heretofore referred to in the authorities cited, and is quite sufficient to turn the scale in his favor on the issue of infringement when, on comparing them with the prior art, it is seen that they are *independent* improvements upon the prior "triple-valve", and not a mere improvement on the patent in suit.

In *Morgan vs. Daniels*, 153 U. S., 120, this Court said (p. 123):

"The grant of letters patent is *prima facie* evidence
 "that the patentee is the first inventor of the device
 "described in the letters patent and of its novelty (*Smith*
vs. Goodyear Co., 93 U. S., 486). Not only is the burden
 "of proof to make good the defense (of want of novelty)
 "upon the party setting it up, but it has been held that
 "every reasonable doubt should be resolved against him."

In *Morgan vs. Daniels* the suit was brought under Sec. 4915, Rev. Stat. by the unsuccessful party in an interference before the Patent Office, against the successful party, alleging that the decision of the Office was wrong and that the plaintiff was really the first inventor of the device in controversy. This Court held, as succinctly and correctly stated in the syllabus—

"When the question between the contending parties as
 "to priority of invention is decided in the Patent Office,

“such decision so made must be accepted as controlling
 “upon that question of fact in any subsequent suit
 “between the same parties, unless the contrary is estab-
 “lished by testimony which in character and amount
 “carries thorough conviction.”

The Court also said that the rule quoted as to the burden of proof under the defense of want of novelty is applicable to a controversy in the courts between a successful and an unsuccessful party to an interference case previously decided in the Patent Office, the language of the Court being as follows :

“These two cases are closely in point. The plaintiff in
 “this case, like the defendant in those cases, is challeng-
 “ing the priority awarded by the Patent Office, and
 “should, we think, be held to a strict proof,”

the Court adding that this rule is more stringent even than the rule applied by the Court below, as stated by it in the following words :

“The complainant on the issue here assumes the burden
 “of proof, and must, I think, as the evidence stands,
 “maintain it by a clear and undoubted preponderance of
 “proof.”

In *Morgan vs. Daniels* this Court further added the following remarks, which are pertinent to the case at bar and refer to—

“the rule which controls a chancellor in examining a
 “report of a master, or to an appellate court in reviewing
 “findings of fact made by the trial court. There is always
 “a presumption in favor of that which has been once
 “decided, and that presumption is often relied upon to
 “justify an appellate court in sustaining the decision
 “below.”

See *Crawford vs. Neal*, 144 U. S., 585.

Camden vs. Stuart, 144 U. S., 104.

Furrer vs. Ferris, 145 U. S., 132.

The reasoning in the opinion in *Morgan vs. Daniels* points out the decided tendency of the courts to sustain departmental decisions on questions of fact, and to hold them as conclusive and final in the absence of testimony sufficient to produce a clear conviction that the Patent Office or the departmental tribunal erred in its conclusions of fact; and that the burden of so proving is upon the party controverting the departmental decision, and that such party must establish the error beyond any reasonable doubt.

If this is the rule applicable to cases in which a defendant, under a plea of want of novelty, attempts to overcome the prima facies of a patent, or when the plaintiff in a suit under Sec. 4915 attempts to overcome a decision adverse to him in an interference before the Patent Office; or is the rule in a suit to set aside a judgment (as in *Butler vs. Shaw*, 21 Fed. Rep. 321), or in a contest between two claimants for land patented by the United States to one of them (as in *Johnson vs. Towsley*, 13 Wallace 72), very much more pertinent is the rule to the case at bar in which (apart from the evidence showing a decision of the Patent Office on the issue of identity of construction, in favor of the defendant by the grant of a broad patent to him), the burden of proof is upon the plaintiff upon the same identical question under the issue of infringement which he tenders by the allegation of his bill of complaint. In other words, the burden of proof to sustain the charge of infringement is in every case upon the complainant and this burden is not discharged by evidence of a character which leaves the question uncertain or doubtful. But even if the testimony offered under such an issue in the Courts is sufficient to create a probability that the affirmative of the issue is true, then under the rules laid down in the cases cited, this effect of the evidence is entirely rebutted and wholly overcome and the burden of proof shifted, by proof of a decision by the Patent Office Department deciding the identical question by a grant to the

defendant of a patent for the identical machine in controversy, especially when, as the record discloses in this case, it was so decided after consideration of the plaintiffs' patent charged herein to have been infringed. The rule in *Morgan vs. Daniels* has been recently applied in *Cartridge Co. vs. Peters* by the Court of Appeals in the Sixth Circuit, 78 O. G., 621, in an able opinion by Judge Lurton delivering the unanimous opinion of the court, in which the learned judge said, in concluding his opinion, that—

“the complainant has not produced that thorough conviction that he is the first inventor of these improvements, which he must do to justify a decree annulling the deliberate and well-considered action of the Patent Office. * * * There are many inexplicable things tending to cast a doubt as to who was the first inventor. * * * On the whole case, however, we lean to the correctness of the judgment of the Circuit Court and of the action of the Patent Office. This mental attitude is one which requires that the decree of the Circuit Court shall stand.”

This doctrine, however, is not new. It is fairly inferable from the reasoning of Judge Clifford in *Corning vs. Burden*, 15 Howard, 252, and of Justice McLean, on circuit, in *Brooks vs. Bicknell*, 2 McLean, 432.

As, however, the decision of the Patent Office is not conclusive, though presumptively correct and decisive in the absence of evidence which fully meets and rebuts it, the court is, therefore, brought to consider and weigh the evidence for and against the correctness of the decision of the departmental tribunal.

A Brief Comparison of the Plaintiffs' and Defendants' Machines.

Let us disregard form and look only at the principles of construction and operation of the two machines respectively, keeping in mind at the outstart the fact—essential to a correct conclu-

sion—that both parties utilize and retain, as a distinctive element in their respective combinations of mechanism, a “triple-valve,” such as shown in patent 220,556 and other prior patents. Both have *now* produced a quick-action machine, evolved from these prior devices; and in such new machine of both parties, the mechanism necessary to perform *all the old triple-valve functions*, are substantially identical, and these are old, and these the world has a right to use, and these remain in *both* the machines of the plaintiff and defendant respectively and operate to perform their usual functions as *triple-valve* mechanisms. They have not been altered or added to in any respect to change or qualify their triple-valve functions in either machine. The mere fact that both parties desired to produce the same additional result, and that both succeeded in that respect, is not of the least importance in determining the question at bar. What we wish to know is, whether or not each party added mechanism to the old device, which produces the new result *in the same way* and by *analogous means involving the same principles* of construction and operation. If they did not, there is no infringement, even though their respective devices produce identical *results* and are *functional* equivalents in that respect.

Recalling to the mind of the Court that the plaintiffs' machine consists of “additional members,” as he calls them, “combined” with the old triple-valve of his prior patent, 220,556, forming two machines in one casing, (the old machine venting auxiliary-reservoir-air as before, and the new or added machine venting only train-pipe air *without passing such air through the old machine*) we find by comparison therewith that the defendants' machine does *not* consist of “additional members” added to the old triple-valve, and thereby constituting *two* machines combined, but it consists of *one* machine, and that the old one, improved, and improved in a part which never before by any one in the world was ever thought could be improved or modi-

fied, viz., by separating the triple-valve chamber into two chambers communicating with each other through a restricted opening; in plain words, inserting a *bushing* or *partition* therein, and so producing differential pressures in the chamber on either side of said partition, by which the *old main-valve* of the triple-valve is made to simultaneously vent both auxiliary-reservoir air and train-pipe air to the brake-cylinder.

This was a great invention by Mr. Boyden. It was a discovery; a revelation of the latent powers of the old machine, made wonderfully effective by the most simple change, and in a part of the device never before attempted to be modified, and which the skill of the mechanic would never suggest to him to alter, add to or modify to produce the effect sought for. The means adopted to produce the effect obtained, *i. e.*, differential pressures, producing the desired effect, could never be *reasoned* out from anything then known in the art; certainly not from anything contained in the plaintiff's patent. It was a most ingenious invention, simple though it is, and the widest possible departure from the principle on which 360,070 is constructed.

No one skilled in the art or otherwise could, from anything contained in the plaintiff's patent, construct or evolve such a structure as Boyden's. The patent in suit does not teach the principles—much less the mechanisms—contained in defendant's machine, and it was never *intended* to teach it, or anything even remotely resembling it, either in construction or operation.

No person, with an understanding of the patent in suit, can logically contend that Westinghouse meant, by anything said therein, to include a triple-valve device in which the *main valve* of such was made to *vent train-pipe-air* or to vent it through the *triple-valve-chamber*, and any person attempting such a change, without also combining with it Mr. Boyden's partition in the valve chamber, would make an inoperative structure that would be worse than useless.

In other words, if we abandon the principle of segregated machines, as defined by Westinghouse patent, we *must* apply the Boyden principle in the reconstruction of the valve-chamber.

This is a leading, forceful and predominant *fact*, and it governs the decision of the question of identity or non-identity.

**The Construction of the Patent in Suit is to be
Qualified and Not Broadened, by Reason
of the Fact that the Device, However
Meritorious in Theory, is Not in
Practical Use.**

Confessedly the invention of the patent in suit, as shown and described therein, is not now made and sold by the plaintiffs, and has not been since 1887 or 1888. (Record, p. 149, line 36.) The reason for its abandonment appears clearly from the evidence in the record (page 126, line 6), and from the remarks of the judges in the New York cases (59 Fed., 594, affirmed, 63 Fed., 962-969); and although it is an operative device, it did not meet the public demand *without the improvements afterwards patented* in Westinghouse's later patent, 376,837. The defendant (Boyden's) device, on the other hand, admittedly operates as efficiently as the *latter*, and is not open to the objections to the former (360,070). The plaintiffs' contention, therefore, seeks to broaden the scope of a *paper* invention, and of the indefinite claim 2 of the patent therefor, to repress a mechanically different thing with which it cannot successfully compete.

In *Long vs. Pope Manufacturing Co.*, 75 Fed. Rep., 635, where the bill was dismissed by the Circuit Court in a case for alleged infringement of a patent which the plaintiff sought to broaden by construction to include the defendant's device, the Court of Appeals, in the First Circuit, in an able opinion by Judge Putnam sustaining the decree below, said:

1. "This patent was taken out in 1862, and, so far as it comes in issue here, it has not been put into practical

"use. Therefore, in determining the inventor's conception of the functions of the claims in issue, of the condition of the art, and of the improvement which he gave to the public, our safest resource, after so long a lapse of time, is the patent itself." * * *

2. "If the functions of the invention were solely those stated in the specification, the claim must clearly have a narrow range, while if the other function now suggested is permitted to aid in controlling its construction, it is entitled to a broad one. It is plain, nevertheless, on all rules, that so much of the mere form given in the specification, drawings and claim, is essential and must be retained, as is necessary in order to accomplish all the functions expressly enumerated therein. * * *

"A function afterwards discovered cannot be used to broaden it, and such a function is available to the patentee only when the patent, construed in the light of the circumstances existing when it is applied for, is broad enough to embrace it. In the case at bar there is nothing to show that the function now claimed for the invention was in the mind of either the inventor or of the Patent Office when the patent issued." * * *

3. "If this invention had been put in early use, and so continued with a long public acquiescence, it might perhaps have safely received therefrom a practical construction more favorable to the complainants. But in view of the rapidity with which mechanical improvements advance in this age, it would be a dangerous precedent to give to a mere paper patent, which has lain dormant for years, a breadth not contemplated on its face by reason of some new function discovered long after its issue, and after that function had been availed of in practice by others. There appear in this case some elements which perhaps would render it not inequitable to permit that result here; but the precedent, if established, would, on the whole, operate more to entrap honest manufacturers than to advance the useful arts."

The principles stated in the foregoing opinion (which has been divided into paragraphs for convenience of comparative reference) are applicable to the case at bar. The device described in the Westinghouse patent in question, has admittedly not been manufactured since it was superseded by the improvement thereon described in the later Westinghouse patent No. 376,837 issued in 1888; it admittedly contained defects which the latter remedied, and which superseded it. This is so clearly shown by the evidence in the Record, and by the opinions of the New York courts that it cannot now be successfully explained away or controverted. Against the principle stated in paragraphs 1 and 2 above, it is sought now by the plaintiffs to give to the machine, through its piston, a new function not contemplated by the inventor nor disclosed in the patent. As said by Judge Putnam, "so much of the mere form given in the specification, drawings and claim is essential, and must be retained, as is necessary in order to accomplish all the functions expressly enumerated therein." Hence, if the plaintiff's contention is correct, that the invention is broad enough in scope and intention to include dispensing with the auxiliary valve and giving the main valve the additional function of admitting train-pipe air, by reconstructing the valve-chamber of the triple-valve element of the combination, or is broad enough to dispense entirely with the segregated passage-way, "directly admitting train-pipe air to the brake-cylinder by utilizing the valve-chamber of the 'triple-valve' element of the combination for that purpose, or is broad enough to include a combination with the 'triple-valve' element of the claim, of "a device for admitting air *directly* from the main-air-pipe to the brake-cylinder" (the rejected and erased claim), or is broad enough to cover, not a combination with the triple-valve element of some *added* part or parts (through which the train-pipe air is vented), but a device which consists solely of a reconstruction of the triple-valve element itself and not employing any of the 'additional

members' described in the specification or any substitute therefor, and which 'triple-valve' element retains all its old valves which also retain all their old triple-valve functions of admitting reservoir air, but perform an additional function, not because of any change in them but solely because of a restricted partition in the valve-chamber of the "triple-valve" element, it is very certain that the patent does not disclose in its specification and drawings as part of the invention, this giving of a new function to the old valves of the "triple-valve" element, and which, as Judge Putnam remarked in *Long vs. Manufacturing Co.*, under similar circumstances above referred to, had been discovered and put in practice by these defendants *after* the issue of the patent in suit, and which would be giving to such patent a breadth not contemplated on its face, as inclusive of an invention not in the mind of the inventor when he made his application, and a scope not contemplated by the Patent Office in the consideration and allowance of the claims in controversy, and finally as establishing a precedent which, as Judge Putnam said, "would operate more to entrap honest manufacturers than to advance the useful arts."

The Construction of the Claims as Deduced from the Face of the Patent.

The patented mechanism consists of a brake device, having for its foundation or principal element in the new combination a triple-valve device such as described in the Westinghouse patent No. 220,556. This device operated to admit air pressure to the brake-cylinder solely from the auxiliary-reservoir. To this device, as so constructed and operated, and without any material change therein, either in its parts or in the mode of operation of any of its parts, or in any of the triple-valve functions performed thereby, the patentee of 360,070 (the patent in suit) *added* two elements, viz, an auxiliary-valve (marked 41)

and a passageway (marked 46) controlled thereby. This valve 41 was purely *auxiliary*, not only in mechanical construction and mechanical operation, but in the function performed thereby; hence (as stated in the patent) it was *independent* of the main valve, and could be plugged up without in any manner affecting the action of the triple-valve, or any of the ports or passages of the latter, and necessarily, in a machine constructed on that principle, the passageway 46 is separate from the triple-valve proper and leads *directly* from the train-pipe to the brake-cylinder.

From the patent in suit we extract the following:

"So far as hereinbefore described, the triple-valve
 "accords in all substantial particulars with, and is adapted
 "to operate similarly to those of my letters patent Nos.
 "168,359, 172,064 and 220,556, and in order that it may
 "perform the further functions requisite in the practice
 "of my present invention, it is provided with certain
 "*additional members.*"

No one can read the specification of the patent in suit without reaching the conclusion that the *essence* of the invention consists in combining *two separate and distinct* machines, in such manner that the old one will, under certain circumstances, *i. e.* when quick action is desired—bring the new one into action, *which latter performs no function whatever of the old triple-valve machine.*

We shall not take up the time of the Court discussing the question of pioneer patents and rules for considering claims therein. It is sufficient to say that under the decisions of this Court (notably *Morley vs. Lancaster*, 129 U. S., 263), no matter whether the *function* performed by the new mechanism is entirely new or not, and no matter how broad is the range of equivalents to be permitted in determining identity of mechanisms, it cannot be, and never has been, sanctioned by this Court that a defendant's device infringes such a patent, even if it perform precisely the same functions, unless its *mechanism* is constructed and operates on the *principles* disclosed in the patent

in question. Indeed this Court has distinctly said so in *Morley vs. Lancaster* in these words (see page 266 of the report).

“The Morley claims are not for a result or effect, irrespective of the means by which the effect is accomplished. It is open to a subsequent inventor to accomplish the same result, if he can, by substantially different means,”

and affirming (*McCormick vs. Talcott*, 20 How., 402), which was a suit on a pioneer patent, the Court said that mechanism will not be held to infringe it unless it “operates on the same principles and performs the same functions by analogous means or equivalent combinations.” In *Morley vs. Lancaster* the defendant’s machine was held to infringe because this Court found that the mechanical devices used by the defendant were known substitutes or equivalents for devices employed in the patented machine to effect the same result; and this language was used by this Court in defining the term “known equivalent” in reference to a so-called pioneer machine.

Scope and Meaning of Claim 2.

Referring again to the face of the patent in suit, to recall the “additional members” which Westinghouse “combined” with the old triple-valve of 220,556 to make up his invention of the patent in controversy, what construction can we put on the claim 2 in question from the information given by the specification and without other aid?

Let us read it, to be reminded that every element expressed in it, even to the “further traverse” of the piston, is old, both singly and in the same combination, in the old triple-valve of 220,556, the only new thing expressed in the claim being the statement of the *function* of the “additional members.” (See R., p. 468 :

“2. In a brake mechanism the combination of a main-air pipe, an auxiliary-reservoir, a brake-cylinder, and a

"triple-valve, having a piston whose preliminary traverse
 "admits air from the auxiliary-reservoir to the brake-
 "cylinder, and which by a further traverse *admits air*
"directly from the main-air pipe to the brake-cylinder,
 "substantially as set forth."

It cannot be logically contended that the claim is comprehensive of means generally, irrespective of its construction or mode of operation, except that it is brought into action by the "further traverse" of the triple-valve piston. We are obliged to import into the claim *some* means to enable the triple-valve piston to perform this *abnormal* or *additional function*; otherwise the claim read literally would be for an inoperative combination and incapable of producing the desired result. This is true for two reasons: (a) because the function of the triple-valve alone is *not* to admit train-pipe air *directly* to the brake-cylinder, nor is it capable of such action, whether on a partial or a full traverse of the piston; and (b) because the triple-valve proper has no ports or passages leading from the train-pipe side of the triple-valve piston chamber *directly* to the brake-cylinder, and consequently, the triple-valve piston (without such ports) could not be capable of "admitting air directly from the main pipe to the brake-cylinder" by "a *further* traverse," or any other kind of traverse.

If there is any mechanical proposition in this case that is not disputed or open to dispute, it is that the "triple-valve" element of the invention in question, is the *same* triple-valve element of the preceding patents mentioned, nothing more and nothing less, and not performing any new, different or other function, *as such*, than it performed when alone and used simply as a triple-valve. Its piston only co-operates in the device patented, to produce the result recited in the claim, because in the performance of its ordinary, usual and old function, its *further traverse* contacts with and moves a new "auxiliary-valve 41" located in its path in the valve casing, which valve normally

covers a port 42, which opens a passageway 43-46 leading to the brake-cylinder. These "additional members" and the arrangement of them in juxtaposition to or in the path of the triple-valve piston (and wholly disconnected therefrom) in the valve casing, is the entire invention.

Indeed, the patent in suit says so, in those words: because after describing in nearly 2½ pages the construction of the old triple-valve proper, then follows (in exactly 22 lines of the patent, and on lines 5 to 27 of page 466 of the Record) the description, *and the only description in the entire specification*, of the construction of the "additional members" with which the old triple-valve of 220,556, is "provided" as aforesaid. The remainder of the specification is taken up with description of the operation of the device, defining triple-valves, and a disclaimer.

Reasoning by exclusion, it is nowhere shown in the specification, that *other means* than the auxiliary-slide valve 41 and the by-passage 43 and 46 may be employed to carry the air *directly* from the *train-pipe* to the *brake-cylinder*.

Beyond doubt the plaintiff is entitled to a broad claim for *this combination*, covering a wide range of mechanical equivalents, but he is not entitled to such a broad construction as to cover *any* and *all* mechanism involving the principle of admitting train-pipe air direct to the brake-cylinder when the old and usual "further traverse" of the triple-valve piston take place. To so hold would deprive any other person from improving or changing or adding to the old triple-valve of the automatic brake, by mechanism integral therewith, and wholly different in principle of construction and operation from the plaintiff's added elements, which will effect the *same result*. The authorities do not countenance any such theory of construction of patents for inventions, whether correctly classed as pioneer patents, so-called, or not.

Having thus ascertained the nature and scope of the invention, from a reading of the specification, let us see whether or

not our views are corroborated by a reference to the file and contents of the application therefor.

The Scope and the Meaning of Claim 2, as Qualified by the File and Contents of the Application.

The record (see pages 705, 714) discloses that the application, as originally filed, contained a claim and statement which will now be quoted, as they are controlling factors in the correct interpretation of claim 2. This *original* claim and this statement were erased by the applicant after rejection of said claim, and of claim 2 now in issue. The statement erased is as follows (R., p. 714):

"Further, while in the specific construction described and shown the function of admitting air from the main pipe is performed by a valve *separate* from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve *integral* with the main-valve and *formed by an extension thereof*, would be included in and embody the essential operative features of my invention."

The original (1st) claim erased, was as follows :

"1st. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, and a "triple-valve, *provided with a device for admitting air directly from the main air-pipe* to the brake-cylinder, substantially as set forth."

The effect of the erasure of said statement and claim is, in law, a disclaimer that the valve element of the combination to admit train-pipe air to the brake-cylinder may be *integral* with the main-valve of the triple and merely *brought into operation* by the piston—in fact, it is an implied admission that it must be separate and independent from the main-valve, moved and brought into register with a

separate, independent and auxiliary port and passage-way (wholly disconnected from the triple-valve element) leading through the casing or chest from the train-pipe direct to the brake-cylinder. This view, if it needed any corroboration, is found in the *letter of applicant* to the Patent Office, accompanying his action *erasing said statement and claim*, in which he said (see Record, page 718, folio 1175):

“It is to be understood that applicant does not seek to broadly claim a device for admitting air directly from main-air pipe to the brake-cylinder. * * * When, however, the triple-valve is *provided* with an *auxiliary-valve*, operated by its piston which performs a new function additional to that of the triple-valve as previously employed, it is believed that *such combination* is wholly novel.”

This statement conclusively implies an *auxiliary-valve* in claim 2. But the contents of this file containing this letter absolutely preclude the possibility of construing the allowed claim 2 (allowed *after rejection*, allowed *after erasure* of above broad statement, allowed after erasure of this original first claim, and allowed *after receipt of this letter* defining the invention of *this claim 2* as a “combination” of an “auxiliary” valve with the old triple-valve, the piston or its “further” traverse being the actuating means), as being for *means generically*, operated by the piston of the triple; and which may be *integral* with the main-valve of the triple, or that the Patent Office intended to grant any such claim.

The Circuit Court recognized the force of this, but avoids its usual, proper and required effect by accepting the complainants' proposition, that the aforesaid *statement* in the specification was erased *because the drawings did not show a device which would warrant such a description*; yet that Court says, the patentee may nevertheless claim that his patent covers such a construction if his *invention* is broad enough to include it.

This is a very startling proposition in the law of patents, and remarkable for its novelty and departure from a line of decisions which are too well established to be so easily qualified or overruled. There is no better established principle in patent law at this day than that the doctrine of equitable estoppel is applicable with full force and effect to forever prevent a patentee who has, pending his application in the Patent Office, erased a broad statement of invention and a broad claim founded thereon, whether voluntarily, but more particularly *after* rejection and objection by the Patent Office, as in this case, from ever afterwards asserting for the remaining claims or any substituted claim, a construction or interpretation which shall be tantamount in scope and comprehensiveness to the original and erased statement and claim.

Sheppard vs. Carrigan, 116 U. S. 593.

Sutter vs. Robinson, 119 U. S. 530.

Roemer vs. Peddie, 132 U. S. 317.

Yale Lock Co. vs. Greenleaf, U. S. 554.

Crawford vs. Heysinger, 123 U. S. 589.

Corbin Lock Co. vs. Eagle Lock Co., 150 U. S. 38.

The decision in *Reese vs. Sewing Machine Co.*, 61 Fed. Rep., 958, affords no countenance for any qualification of this salutary rule; besides, the facts in that case have no parallel with those in the case at bar.

Westinghouse's application was filed November 19, 1886, containing the above quoted statement and claim. That erased (1st) claim and the (2nd) claim now in controversy in this case were both rejected. The Circuit Court seemed to think that the prior reference on which the claims were rejected did not in fact operate to negative the novelty of said erased claim, but that the erasure thereof was for the reason hereinbefore referred to. The Circuit Court was entirely in error in this; but whether it was or not is entirely immaterial. The applicability of the doctrine of estoppel is not limited to cases in which the party

happens to rightfully exercise his right of express or implied disclaimer. It is not dependent upon whether his *judgment* was right or wrong, but upon his act. It would be remarkable indeed, if the deliberate act of a party cancelling a broad claim and a broad statement of invention in the performance of a public act of patenting an invention, where his act is purely *ex parte*, could afterwards declare that his act was a *mistake of judgment*, or that it was done for some reason not apparent on the record, and evidence of which rests only *in pais*, and is not accessible to the public. The latter is entitled to be told *plainly* by the record, as Justice Miller said in *Merrill vs Yeomans*, and Justice Bradley repeated in *Keystone Bridge Co. vs. Phœnix Iron Co.*, *what it is that limits its rights* and what exclusive privileges have been carved out and given to the patentee by the monopoly granted.

It will be observed on reference to the file wrapper and contents of the application (see Record, page 714, folio 1166) that the *original* claim 1, which was erased, was in the following words :

“1. In a brake mechanism the combination of a main
“air pipe, an auxiliary reservoir, a brake cylinder, and a
“triple valve *provided with a device* for admitting air
“directly from the main air pipe to the brake cylinder,
“substantially as set forth.”

The second claims was, and is :

“2. In a brake mechanism the combination of a main
“air pipe, an auxiliary reservoir, a brake cylinder, and a
“triple valve *having a piston whose preliminary traverse*
“*admits air from the auxiliary reservoir to the brake*
“*cylinder, and which by a further traverse* admits air
“directly from the main air pipe to the brake cylinder,
“substantially as set forth.”

The words contained in each of these claims not found in the other are printed in italics for the purpose of ready comparison, and from which it will be seen that they do not differ in substance, when it is considered that the “further traverse” of the

piston is old, and existed in the combination expressed in the 1st claim as much as it does in the 2nd. The two claims are, and doubtless were intended to be, broader than the remaining claims, and the language of the first clearly indicates that it was intended to be broader than the 2nd, because it claims a triple valve provided with means generally, i. e. *a device of any kind* operating to perform the particular function or result stated in the claim, which is the *same* function or result stated in the 2nd claim.

The record shows that this original claim 1, as well as the present disputed claim 2, precisely as the latter now appears in the patent, were rejected by the Patent Office on reference to Boyden's earlier patent No. 280,285, of June 26, 1883.

Following this letter of rejection, the applicant acquiescing therein as to said claim 1, erased the said claim and substituted therefor the present limited and comparatively narrow claim 1 (see file wrapper and contents Rec. pages 717-718) and at the same time erased from the specification the statement quoted, that the "separate valve" could be integral with the "main-valve," and explained that *claim 2* implied the presence of an "auxiliary" valve in "combination" with the triple-valve, in the letter to the Patent Office asking reconsideration and allowance of said claim 2 (see Record, page 718, folio 1175). It is impossible to avoid the effect of this implied disclaimer. In the opinion of the Circuit Court the learned Judge uses the word "so-called" disclaimer, but uses it in reference not to this *erased* clause, but to an *inserted* clause at the end of the specification in reference to the Boyden Patent of 1883. The learned Judge discussed the effect of the Boyden prior 1883 patent, and the *inserted* clause, differentiating it from the invention in suit, but wholly omitted the most important implied disclaimer, arising from the fact that the broadening clause herein first above referred to, and the original first claim founded thereon *were deliberately erased by the patentee after objection and rejection* by the Patent

Office. It is these acts of the patentee which constitute the disclaimer and not the insertion of the clause to which the learned Circuit Judge referred, His opinion construed the 2nd claim in suit as covering, in the words of the erased 1st claim, every "triple-valve *provided with a device* for admitting air directly from the main air pipe to the brake-cylinder," provided it was brought into operation on the "further traverse" of the piston, erroneously assuming that such "further" traverse was *per se* new. Obviously he was wrong, and was correctly reversed.

It is wholly unnecessary for the purpose of the point we are now presenting, to discuss or decide whether or not the Boyden prior patent of 1883 anticipated, qualified or negatived the novelty, in whole or in part, of either of the claims in question. Suffice it to say that the applicant's attorney, at the time of making said amendments, and more particularly at the time of inserting the clause at the end of the specification differentiating said Boyden prior device, *accompanied the same by a letter* in which he refers, not only to the *function*, but to the *structure* of the Boyden patent, and admits in express words *that no claim is made to broadly admit train-pipe air directly to the brake-cylinder*, which, of course, means in a triple-valve device, for that is what the applicant was discussing and what he was distinguishing against. However that may be, he says in said letter, as plainly as the English language can convey the meaning, that his device consists of a *valve auxiliary* to the "triple-valve as previously employed," to perform an additional function, and that its novelty resided in a *combination* of such auxiliary-valve with the old triple-valve. No other meaning can be taken from the applicant's letter, which is as follows (see R., p. 718):

"When, however, the *triple-valve* is *provided* with an "*auxiliary-valve* operated by its piston, which performs "a new function *additional* to that of the *triple-valve* as "*previously employed*, it is believed that such *combination* is wholly novel."

There is nothing in this letter indicating any novelty in the "further traverse" of the piston as a new movement *per se*, because it has no further or other traverse than it had before. The effort was to show that one of the *old* movements of the piston does something which it did not do before **and solely because** of some "additional members" which it actuates on this movement. Every word of this letter indicates that the invention does *not* consist in some improvement *in and of the triple-valve itself*, but of a *combination* of the triple-valve with some *added* or *auxiliary-valve* whereby the *combined* mechanism (not the piston alone, nor the auxiliary-valve alone), may, through the action of the triple-valve piston, produce some new result or perform some new function; and it is "such combination" which the letter says the applicant believes to be wholly novel. And what is said in that letter is not disputed. What is disputed is that the 2d claim shall be construed to be for means which are *not* auxiliary to and not *independent* of the triple-valve as *previously employed*; and for means which are *integral* with the triple-valve to enable it to perform a double function *in and of itself*; which latter is a character of structure which by no stretch of imagination could have been contemplated by the Patent Office officials, as intended to be within any claims of Mr. Westinghouse's patent as allowed to him; and is a construction of the claim involving wholly different principles of mechanical construction and operation; and which could not possibly be evolved from any description contained in the patent in suit.

Claim 2 is in Form and Substance for a "Combination."

We may be pardoned for referring again to the file and contents of the application for corroborative support of the following view of the claim in question. The letter of the patentee, Record, p. 718 (written after rejection and erasure of original claim 1 and present claim 2, and asking reconsideration and allowance of present claim 2, notwithstanding its previous

rejection), clearly shows (as does also the language of the claim itself), that the invention patented is a true *combination*, in the technical sense of that word, with a "triple-valve," of the "additional members" described in the specification, or their mechanical equivalents, which are to be "auxiliary" to the "triple-valve" and "independent of the main-valve" thereof.

The theory advanced by Westinghouse counsel that the idea of a "combination" may be brushed aside, is not sound, because not only is the claim in form for a combination, reciting the several elements thereof, but the claim uses the word "combination;" and the explanatory letter referred to says, "when, however, the '*triple-valve*' is provided with an '*auxiliary-valve*,' etc., it is believed that such *combination* is wholly novel." Is not the invention covered by this very claim (which is the one in dispute), therefore, by the force of these words, a true "combination" in the technical sense? How, therefore, can the new elements—the "additional members"—be wholly dropped out, and the "triple-valve" element (which the specification says is the well-known triple-valve of 220,556 with its graduating-valve and main-valve), be reconstructed to make its *same identical valves* do something which as valves of a "triple-valve" they could not possibly do, and hence make it a wholly different thing from the "triple-valve" expressly made a separate and distinct *element* of the *combination* patented? Moreover, such a substitution of a different "triple-valve" element breaks up the "combination" referred to in the applicant's letter, because it not only discards entirely the "additional members" referred to in the specification, or any mechanical equivalent thereof, or any substitute therefor, but it requires, in order to produce the result sought for, a remodeling of the valve-chamber of the "triple-valve" element in order that while retaining all its (old and usual) triple-valve functions, it shall be enabled thereby to produce the additional result sought for; and this reconstruction of *that element* the Patent Office has correctly ruled is the invention of Mr. Boyden.

Several Views Under which the Machines may be Compared.

1. It seems impossible to conceive of two machines so alike in results, and yet more widely and radically different in principle of construction and operation. No man could construct the defendant's device nor obtain the slightest aid in so doing, from anything contained in the plaintiff's patent, not even the patentee and co-plaintiff, Mr. Westinghouse, whom, it is not inappropriate to add, has not testified in this case nor attempted to assert to the contrary. This is a significant circumstance, and entitled to be considered, more especially if our contention be well founded in law, that the offer of defendant's patents in evidence rebutted the plaintiff's *prima facie* case and shifted the burden of proof.

2. Another principle—or rather maxim—of the patent law, is applicable here to aid us in determining this issue of fact viz.: the rule that what will infringe if later will defeat if earlier.

Let us, therefore, suppose that the triple-valve device of the defendant (which has no by-passage and no "auxiliary-valve," but in which train-pipe air is admitted to the brake-cylinder by a remodeling of the old "triple-valve" element), *preceded* Mr. Westinghouse's invention of the patent in suit, the latter would be the very first to state, that his invention was not anticipated thereby, because (he would argue), that taking his old "triple-valve" of 220,556 and *without remodeling it in any respect*, he made a new "combination" (in the strictest technical sense), with such "triple-valve" (and without thereby changing or adding to or subtracting from any of its parts or of the functions of any of its valves or chambers), of certain "additional members," in every sense (both physically and functionally), so *auxiliary* to the "triple-valve element of the combination that it must not be "integral" with the main-valve thereof (see statement erased from specification), and must be "independent" thereof. He could, therefore, truly and correctly contend

(if Boyden's device in suit preceded him), that the latter did not anticipate the "combination" of elements which he has thus shown and described in his specification, and pointed out in his claims—by *express words* in all the claims but the 2d, and by clear implication in the 2d claim, as was obvious to Judge Lacombe as stated in his opinion in 65 Fed. Rep. 99.

3. It seems almost a work of supererogation to cite other proof of differentiation, but let us, out of caution, do so. It has been seen that the plaintiff's device as shown and described has in combination a triple-valve, and added thereto a separate and segregated passage-way leading directly from train-pipe to brake-cylinder and a valve controlling it which is auxiliary to the triple-valve entirely outside of it, and *physically disconnected from it*; while the defendant's device has no additional passage-way at all, leading either directly or indirectly from train-pipe to brake-cylinder, and of course has no auxiliary or other valve to control a port or passage which has no existence, but consists, not of a "combination" with an old "triple-valve" element of some auxiliary device, but of the old "triple-valve" element remodelled by simply partitioning its piston chambers, whereby the old valve-chamber became a passageway not only for reservoir-air as it always was and still is, but for train-pipe air as well, and the main valve of the triple-valve not only admitted reservoir-air (as it always did and still does), but admitted train-pipe air as well on a full stroke of the piston. But this full or further stroke is the same action and for the same purpose as and for which it always was performed, *i. e.*, actuating the main-valve for admitting maximum reservoir pressure for emergency purposes. The mere fact that in plaintiffs' device another and auxiliary-valve is so placed *outside* the triple-valve chamber that on a full stroke of the piston it will strike such added valve, does not make such *old further traverse* a new function of the piston. The *combination* with such piston, having such a stroke, of an added element—a new valve—gives the *entirely* a

new function, but it is unsound and fallacious to say that the *further traverse* is per se a new function of the *piston*.

(4.) In view of what has been said, let us look at the collateral circumstances in respect of the *by-passage* controlled by this new *added* valve, the two constituting the "additional members" described in the specification. How can the plaintiff reasonably contend that the word "directly" in the claim does not imply a segregated passageway, and that "auxiliary" does not mean "additional" in respect of a valve which the description says is to be "independent" of the valves of the (old) "triple-valve" element in the "combination" pointed out in the claim? The surrounding facts preclude the possibility of any such contention being sound, and of these it suffices to mention the following only.

(A.) The disclosure is shown in Boyden's earlier patent of 1883 (four years in advance of Westinghouse's patent in suit), of a "triple-valve" of the slide-valve form, with a check-valve opening in its piston (exactly the same in that respect as defendant's present alleged infringing device), which operated *to admit train-pipe air through the triple-valve chamber* (such air being admitted, however, to augment the brake-cylinder pressure), thus showing *how* train-pipe air could be admitted to the brake-cylinder *through the triple-valve chamber* without any separate or additional passageway. THIS WAS FOUR YEARS BEFORE THE DATE OF THE PATENT IN SUIT. (See Record, page 498, and cut opposite).

(B.) To that earlier device, Mr. Boyden added in 1888 the further invention of producing *differential pressures* in the "triple-valve" chamber by means of a *partition* therein with a restricted opening, and so operated the old valves (not new or additional ones), of the "triple-valve" to admit train-pipe air in advance of or simultaneous with reservoir-air, and thus produced "quick action," so-called.

(5.) Before concluding the presentation of our views on this particular aspect of the cause, we desire to call the attention of the Court to, and to thank our learned opponents for, the very frank and truthful admission contained on page 7 of the Westinghouse Supplemental Brief, as follows:

"The two valves of defendant's structure are *both* capable of *admitting auxiliary reservoir air only*, **"when the partition 9 is absent**, because in the structure as thus organized, *there are no such air-passages* as to make it possible for **any movement** of the triple-valve piston to result in opening **any port** by which *train-pipe air* could be admitted to the brake-cylinder."

The following conclusions logically follow from this absolutely true fact, so admitted:

(a.) The defendant's structure (without the partition 9) has two valves—a graduating-valve and a main-valve—and a piston with two movements—a preliminary and a further—the first movement actuating the graduating-valve and the further movement actuating the main-valve; and this structure, *so organized* (without the partition 9) will admit only reservoir air to the brake-cylinder, *no matter whether the piston makes a preliminary or a full traverse*; and the defendant's device so constituted (without the partition 9) will neither produce the new result of the plaintiff's device (admitting train-pipe air,) nor in any manner interfere with the plaintiff's claim, taken in its broadest and literal sense; and finally, that this defendant's device (without the partition) is an operative "triple-valve" for admitting *reservoir air* (only) by means of two valves actuated by the two movements of the piston, respectively.

(b.) That the identity of *said device*, WHEN THE PARTITION IS PLACED IN THE VALVE-CHAMBER, with the Westinghouse invention in suit, is, therefore, dependent solely upon whether or not Mr. Boyden's reorganization of the *valve-chamber* of the "triple-valve" element, AND WITH NO OTHER CHANGE WHATSOEVER, is the *mechanical* equivalent of Mr. Westinghouse's

"combination" with a "triple-valve" (as an entirety and unaltered), of two other distinct elements (a separate passage-way 46 and an auxiliary-valve 41 to control it), the latter being in no sense any part of the "triple" nor affecting its action or function as *such*, but on the contrary being "additional members," distinct elements or integers, in a true "combination" of elements, some old and some new—to produce some *new* result?

(c.) This is exactly the proposition into which Judge Hughes crystallized the whole case when he said, in his opinion (R., p. 880).

"As there was no novelty in the extreme traverse of the old triple-valve piston, it must be eliminated from consideration and the mechanical equivalency of Boyden's device of the partitioning ring integral with the triple-valve itself, on the one hand, and on the other hand, the Westinghouse device attached to the triple-valve, and consisting wholly of apparatus not integral, but segregate, individual, several, *additional to and independent of it*, depends upon the character of the two devices themselves, considered and *compared apart from* the extreme traverse, and not upon their being put in action by the extreme traverse *of the triple-valve piston*."

And this proposition he repeats in a paraphrased sentence on previous page (878), premising it by the statement that it is "the question at bar" thereby expressly saying that it is *the* question, the decision of which ruled the decision of the case and constituted the matter adjudicated.

His answer to his own question thus tersely put, twice in the opinion was "that they seem to us to differ as widely from each other as two devices for accomplishing the same result can well differ." (R., p. 880, folio 1419.)

He was undoubtedly correct. And his conclusion is corroborated by the paragraph we quote above from page 7 of plaintiffs' supplemental brief.

Comparison of the Devices by Comparison of the Functions of Their Pistons.

The error underlying the Westinghouse argument to show "substantial identity" is that while they admit that the "further traverse" of the piston is *per se* old, they argue that it performs a new function when it actuates *any* valve and opens *any* passage to produce the *new result* of admitting train-pipe air.

Their contention in this regard is untenable, (1) because so broad a construction amounts to a reinstatement of the rejected and erased original claim 1 for the "combination" with a "triple-valve" (having *two movements* of its piston) of "*a device*" for admitting, &c.; and (2) because while it is true of the Westinghouse machine that its "further traverse" of piston does something which it did not do before, *it only does it because* of the true "combination" therewith of an *added* valve and an *added* passageway. But it is not true of the Boyden machine, because it is PHYSICALLY IMPOSSIBLE for HIS piston to do something which it did not do before, for his piston has the same two movements it had before, *it controls the same two valves it did before and in the same way*, and it is not combined with nor does it actuate any new or added valve, nor control any new or added air-passage, and, in fact, does nothing more nor less than it did before, but simply actuates the old valves which governs the same old "triple-valve" passages that they always controlled and exactly in the same way.

Obviously it is the *partition* in the valve-chamber (producing differential pressures), and not the partition plus the *piston*, that produces the new function or result in Boyden's machine. It is not even true that these differential pressures are produced only on a movement of the main-valve 22, which occurs on the further or full traverse of the piston; but if it were so, it still would not sustain the plaintiff's proposition (as respects the

Boyden machine), that this further movement of the piston is the primary cause or in any manner aids in the production of the new result, because this further movement of the piston does not co-act with the partition, it co-acts with the *(old) valves* and only *in the same way and exactly for the same purpose as before*. Take the partition out of the device and the fact is demonstrated to an absolute certainty.

The plaintiffs have confounded the principle of their own machine with ours in respect of the alleged new function performed by the piston, because, in respect of theirs, their contention is quite true—for in theirs the piston on its further traverse does something which it did not do before—it contacts with and moves a *new* valve, and which thereby opens a *new* air-passage; but it is a mistake to say, even in respect of *their* machine, that it is the further traverse alone which produces the new result of admitting train-pipe air, because obviously it is the result solely of the “*combination*” with such “further traverse” of an *added valve* and an *added* air-passage, *all of which co-act*, and *must* co-act to do this new thing.

On the other hand, in the Boyden machine the *piston* does not co-act with any new valves, *for there are none*; and it does not, either directly or indirectly, open any new passageway, *for there is none*; and surely it does not co-act with the partition, nor does it co-act in any new way with the *main-valve 22*, to produce this *new result*, in that it moves *that* valve only on its further traverse, for the very obvious reason that it opens *that* valve now, exactly as it opened it before (in prior triple valves) to wit, on its “further traverse,” and *only* on its further traverse.

Some notice ought to be taken of the assertion in Westinghouse supplemental brief, pp. 6 and 7, that the Boyden device, if stripped of its partition, is a “structure which no one uses or wants to use.” We might truly say the same thing of plaintiff's automatic device of their patent 220,556, if we add—when they (the public and users) can get either of the improved devices of either of the patents in conflict in this case. It is to be

observed, also, that the plaintiffs do not attempt to deny, (1) that the device (without the partition) is a perfectly practical and useful automatic triple-valve; (2) that it has two valves and two movements of its piston, operating said valves in the manner already stated; (3) that it is free to be used by anyone since patent 220,556 expired; (4) that it contains the principle of delivering reservoir-air by means of a graduating-valve and a main-valve, the former doing ALL the *graduating work* and the latter doing none of it, and acting only for "full and emergency application" work, and then only on a further or final traverse of the piston. This is the principle and mode of operation of the expired patent 220,556, and we challenge our learned opponents to deny it or qualify it; and we further assert that Boyden's device (when stripped of its partition) becomes a practical and useful and complete embodiment of the device of the expired patent 220,556; and which assertion it would not be left to us to make, if that patent was still in force.

But, suppose this was not so, this court will be unable to find anywhere in any of the briefs of our opponents a denial of our proposition, (which alone is the material subject) that the Boyden machine (if stripped of its partition) is equally with the machine of 220,556 a practical, useful and complete device to admit reservoir-air to the brake-cylinder, both for graduation or service, and also for emergency work.

The argument made in Westinghouse's supplemental brief that the "triple-valve" which Boyden improved by partitioning its valve-chamber, is a device unknown in the prior art because it has two valves and not one valve, is erroneous for two reasons: *First*, because patent 220,556 is expressly for a graduating-valve additional to the *main-valve*, both valves for *reservoir-air* admission, and *that patent is not confined to the slide-valve form*, but would include the poppet-valve form, as Westinghouse would quickly assert if the patent was still in force, and hence would include a "triple-valve" (without Boyden's partition) but

with his graduating-valve i, j, k and main-valve 22, as now used by him. *Second*, because, as correctly stated by Judge Morris (R., p. 846, folio 1367), that

“The use by Boyden of a central opening through the
“triple-valve piston to admit train-pipe air to the triple-
“valve chamber was not new, nor the use of a poppet-
“valve for the main-valve of the triple, both of these
“constructions having been shown in the Westinghouse
“patent 141,685 of May 24, 1873.”

Note.—Such a method of feeding-in train-pipe air *to charge the reservoir* was old, as the Judge says; and he might very well have added that such a central check-valved opening in the piston to admit train-pipe-air *to the brake-cylinder to augment the pressure, was old and was the invention of Boyden* and was described in his 1883 patent—the very patent on which this disputed claim 2 of Westinghouse’s patent in suit, was originally rejected, and against which Westinghouse distinguished in his letter by claiming that his (Westinghouse) device was a “combination” with a “triple-valve” of an “auxiliary-valve” &c.

The attention of the Patent Office was also called to this, by a paragraph in Boyden’s 1892 patent, No. 484,134, as follows (see R., p. 797):

“In my present invention I use the check-valved feed-
“passage of my 1883 patent, leading from the train-pipe
“through the triple-valve piston to the main-valve cham-
“ber, and thence both to the auxiliary-reservoir and the
“brake-cylinder, for the double purpose of supplying the
“auxiliary-reservoir and also enabling train-pipe air to be
“vented directly through the main-valve chamber into
“the brake-cylinder to aid in supplying the brakes in
“emergency stops.”

Comparison of the Facts in the Case at Bar with the Facts Involved in Burr vs. Duryee and Gill vs. Wells.

(See illustrations on folder, opposite p. 53 of this brief).

The opinion of Mr. Justice Clifford in *Gill vs. Wells*, 22 Wallace 1, suggests three several tests we may apply to the facts in the case at bar to determine the correctness of our general conclusions:

I. It was said by Judge Clifford that the dropping out in the reissue claim, of the tunnel or trunk for directing the fur to the cone, and substituting "means for directing the fur to the cone" made the reissue void as for a *different* invention. *Sem-ble*, it would have been held none the less a *different* invention if its identity had been the subject of inquiry as an alleged infringing device in a suit charging infringement of the original patent.

II. Let us now suppose that Westinghouse had amended and reissued his patent in suit (as Wells did), by eliminating the description of the segregated passageway leading *directly* to the brake-cylinder, and by dropping out the auxiliary or additional-valve and substituting therefor a description of and claim for a device (such as Boyden's), in which the "triple-valve" chamber was used as the so-called *direct* passage, and the *main-valve* of the triple employed not only to do its own work as before, but endowed with a new and *additional* function by a *remodelling of the valve-chamber of the "triple-valve" element* of the "combination" of the original patent, and by means not even remotely suggested in the specification and *solely whereby* one of the old valves performed a new function. Can it be doubted for an instant that this Court would say without the least hesitation, that such a reissue was for a *different* invention? It is none the less different because it is the subject of a subsequent original patent to a different person.

In *Gill vs. Wells*, 22 Wallace 1, the learned Judge considers the question of identity under the doctrine of equivalents, and states it thus :

“Whether one device is or is not an equivalent for another is usually a question of fact * * and the rule is that if the defendant omits entirely one of the elements of the patented combination, without substituting any other, he does not infringe, and if he substitutes another in the place of the one omitted, which is new or which performs a substantially different function, or if it was not known at the date of the plaintiff's patent as a proper substitute for the omitted element, he does not infringe.”

These remarks are pertinent to the case at bar, in which the “additional members” constituting the only novelty in the patented combination, are omitted entirely, and nothing substituted for them to perform their function, it being performed by mechanism operating on a different principle and not known at the date of the plaintiff's patent but invented afterwards.

III. Another view of the case at bar may also be taken. Beyond doubt a patent is a contract and the consideration for the monopoly is the description in the specification, not alone of the specific mechanism shown in the drawings, but a full, clear and exact description of its mode of operation, i. e., its principle of construction and operation, in order that the public may be able, after the expiration of the monopoly, to make, and use the invention in all the possible forms or modifications, embodying the principle or mode of operation disclosed, that would be suggested to a mechanic skilled in the art. Looking at this Westinghouse specification of the patent in suit, in that light, can any one fairly say that it teaches that the “triple-valve” element of the “combination” need not be the triple-valve in any of its various forms referred to in the specification, but may be a triple-valve provided with modifications (not described and not then known) to produce differential pressures therein and

thereby give different and additional functions to *its* valves, and that by so doing, the directions of the patent to provide an "auxiliary" valve "independent" of the triple, and a separate passageway leading "directly" to the brake-cylinder, *may be disregarded?* We fail to find anything in the specification which teaches this, and not a single person interested in the case, either party, witness or counsel, has been bold enough to assert that it does. Yet it is necessary that it should in order to find identity of the defendant's device with the machine of the patent in suit.

In *Burr vs. Cowperthwait*, 4 Blatchford 163, which was a suit on the Wells patent for a machine for making hat bodies, the Court (Ingersoll, J.), stated the rule of *O'Reilly vs. Morse*, (15 Howard 62, 119), as to functional claims, and applied it to the case there under consideration in language which may aptly be applied to the case at bar.

In that case the means or mechanism used by the defendant produced precisely the same *result* as the patented mechanism, and the functions of certain old parts of the two devices respectively were identical; but in the plaintiff's patent it was pointed out that it contained a channel or way interposed between the picker-cylinders and the revolving cone, combined with means to guide or direct the sheet of fur on to the revolving cone, which said guiding or directing elements (which distinguished the novelty of the machine), were found to be wholly unnecessary in the defendant's machine and not contained therein, although said machine produced the same results as the plaintiff's of directing the fur to the revolving cone, and the same variable thickness of fur by controlling the manner of feeding the fur. The Court held that there was no infringement. The same construction was afterwards given to a subsequent re-issue of this patent, in *Burr vs. Duryee*, 1 Wall. 531, and again on a further re-issue of the patent, in case of *Gill vs. Wells*, 22 Wallace 1.

After the decision on the Wells patent, in *Burr vs. Cowperthwait*, the patent was re-issued to cover, in the combination with the rotating exhausted cone, *means* for directing the fur therto, instead of the specific means formerly claimed and described in the specification. As thus re-issued, the patent was passed upon by this court in *Burr vs. Duryea* 1 Wallace 521, in which Justice Grier, delivering the opinion of the court stated several principles, aptly pertinent under a similar state of facts in the case at bar, as follows :

“An infringement involves substantial identity, whether that identity be described by the terms ‘same principle’ same ‘modus operandi’ or any other * * *.”
 “The argument used to show infringement assumes that every combination of devices in a machine which is used to produce the same effect, is necessarily an equivalent for any other combination used for the same purpose.”
 “This is a flagrant abuse of the term ‘equivalent’ * * *.”
 “To constitute an infringement it must be a copy of the thing described in the patent, either without variation, or with such variations as are consistent with its being in substance the same thing.”

In that case it appeared that the defects in prior machines resided in their want of means to *guide and direct* the fur to the revolving cone and deliver it thereon in variable thicknesses at different points. *It was conceded that Wells, the patentee, was the first to produce that result in such a machine ;* and great stress was laid upon that fact in the effort to induce this court to give a broad range of equivalents for the *expressed* novel element (in *Burr vs. Cowperthwait*) and to the re-issued 1st claim, (in *Burr vs. Duryea*), for the indefinitely stated “means for directing the fur-bearing current,” as the novel element in the combination made the subject of the re-issue claim.

In both cases, however, the courts refused to give undue effect to the so-called pioneership of the invention, as to make it cover “means generally ” for directing the fur. It would

not have helped the patentee to have added "when operated or brought into operation by the driving mechanism," if such driving mechanism was old in such machines. No more can similar words, "actuated by the piston on its further traverse," help the plaintiff here to claim "means generally" for admitting train-pipe air "directly to the brake-cylinder." Such introduction of actuating devices into an otherwise indefinite claim do not help it out, when such actuating means are shown to be old and acting as such as they always heretofore acted in like machines, which differ from the patented machine only in not containing as an "additional" element, the "means" for producing the new or added function, in the new "combination" made up by adding to the *old* machine such new "means." In that case, the machine of the defendant, Duryea, was a machine patented to one Boyden, in whose patents statements were contained (exactly as in the Boyden patent in the present case at bar), that the object was to produce the same result as the Wells machine, but by discarding the Wells principle and mechanism, the words of *that* Boyden patent being quoted therefrom in the report, as follows, (1 Wallace, p. 562-563):

"This invention relates to an improved mode of directing or guiding the fur, as hereinafter fully shown and described, *whereby trunks and all other comparatively complicated appliances hitherto used for the purpose are dispensed with*, and an exceedingly simple and efficient device substituted therefor.

"The invention consists in placing directly in front of the picker a plate so bent or curved that its surface will have a certain relative position with the axis of the picker and the surface of the cone, and give such a direction to the fur as the latter is thrown on it by the rapid motion of the picker that the fur will be drawn properly on the cone by the exhaust or suction within it."

Later on in the opinion, this Court explained away the so-called "substantial identity" of the two machines, in its own language, differentiating it from Wells, as follows (see page 572 of 1 Wallace):—

"Now the machine of Boyden has not one of the peculiar devices or combination of devices of the Wells machine, nor any substantial identity with it, unless by substantial identity is meant every machine which produces the same effect. These abstract phrases 'substantial identity', 'equivalent', 'mode of operation', &c. are often used in such a vague and equivocal manner that they mystify and lead many to absurd conclusions, who will not distinguish between things that differ. That two machines produce the same effect will not justify the assertion that they are substantially the same, or that the devices used by one are, therefore, mere equivalents for those of the other. There is nothing in the Wells machine, or its devices, which suggests the peculiar device employed by Boyden. His machine has no tunnel, no cap, no flap, nor any equivalent thereof, nor does it incorporate in its structure the substance of the first invention. There is nothing to be found in the specification of Wells which would ever suggest the peculiar device of the Boyden machine. As an improvement it has more claims to originality than that of Wells."

Later on in the opinion, the Court comparing the specifications of the plaintiffs' and defendants' patents, said (see page 573 of report):—

"No one who reads the two specifications, or inspects the two machines, can aver that they contain the same combination of mechanical devices, or substantially the same, to produce the desired affect. Not one of the devices, or its equivalent, used in one is to be found in the other, nor is its mode of operation the same. The argument used to show infringement assumes that every combination of devices in a machine which is used to produce the same effect is necessarily the equivalent for any other combination used for the same purpose."

It must be remembered that this finding was, notwithstanding the fact, as stated by Judge Ingersoll, and so argued in this court (page 551 of report), that "before the discovery of Wells, no machine was known or used that did, by *any means*, direct a sheet of fur on to a section of a revolving cone, * * to form a bat of fur on the cone, * * of the desired shape and thickness, * * at the will of the operator." And it may also be broadly and properly observed that the re-issue claim was for "means for directing the fur-bearing current."

This case has never been overruled, but, on the contrary, was followed, in a subsequent second re-issue of the same patent, in *Gill vs. Wells*, 22 Wallace, 1; and the same interpretation of the *actual invention* adhered to, notwithstanding the general, broad and indefinite language of the re-issue claim.

Strong efforts were made in *Burr vs. Duryee*, to urge upon this Court the so-called pioneership of the Wells machine, but this Court said, defining pioneership :

"We are of the opinion that the invention of Wells was * * not founded on any new discovery of the application of any element or power of nature to produce an effect. He was not the first to devise the application of a vacuum to a cone for the purpose of forming and compressing bats for hat bodies. * * He has improved this machinery by his peculiar devices * * combined in a machine which however failed to be automatic till further improved. * * As required by statute, he truly and correctly stated the principle or mode of operation of his machine and the functions performed by its several devices. * * He has a valid patent covering his whole invention—no more, no less."

These remarks in *Burr vs. Duryee* were made in respect of facts exactly parallel to those in the case at bar. It cannot be pretended that the Westinghouse patent in suit is a pioneer within the true definition above described; it cannot be pretended that it discloses for the first time the principle or idea of quickening the serial action of the brakes by venting the train-pipe

at intervals at or near each of them (R., p. 68, l. 7, and R., p. 759, l. 42); it is not pretended that the earlier Boyden patent (R., p. 498, l. 3) of 1883 (4 years ahead of Westinghouse) did not admit train-pipe air as well as reservoir-air to the brake-cylinder, and it is expressly admitted in the applicant's letter to the Patent Office, that it is not intended by his claim 2 to cover broadly the admission of train-pipe air to the brake-cylinder (R., p. 718, l. 37)—and of course he meant in a "triple-valve" device, for that is what he was distinguishing against, for he was endeavoring to show that Boyden's prior patent of 1883, for a triple-valve device in which train-pipe air was admitted to the brake-cylinder was not a quick-action device.

In the case at bar the plaintiff has strongly urged this Court to overlook differences in mechanism of the respective devices and obvious differences in their principle of construction and operation respectively, on the plea, whether true or not, that Westinghouse was the first to put into practical form a triple-valve device having additional members which performed the additional function of admitting train-pipe air to the brake-cylinder to quicken the action of the brakes. In other words, having, as he alleges, whether true or not, been the first to produce this result, he asks the Court to construe his patent so broadly as to cover every device to accomplish that purpose which is made a part of an old triple-valve, and operates in conjunction therewith. To sustain such a contention at this late day, would be to overthrow a long line of decisions to the contrary. Precisely the same claim and the same contention was made in *Burr vs. Cowperthwaite*, supra, in which the Court admitted that:

"It is clear that before the discovery of Wells' no machine was known or used that did by any means direct a sheet of fur on to a section of a revolving, exhausted, perforated cone or other form, parallel with the axis so as to form a bat of fur on the cone or other form, of the desired shape and thickness in properly regulated quantities at the will of the operator." * *

In that case the bill was dismissed, because the Court did not find in the defendant's machine the mechanism described in the patent, or the mechanical equivalent therefor to control or give direction to the sheet of fur carried by the current of air to the cone. Nor was there anything substituted therefor, it having been found in the defendant's machine (which was the same machine as in Burr vs. Duryee and Gill vs. Wells), that the current of air, which carried and directed the sheet of fur, was controlled by the picker-cylinders, *without the aid of the plaintiff's guiding or directing devices, or of any substitute therefor, or of any device, in fact, interposed between the picker cylinders and the rotating cone.* The Court said in its opinion that it was a complete and useful machine without any such mechanism or any guiding device being interposed between the parts named for guiding and directing the fur to the cone. The language of the opinion being as follows, (4 Blatch, 171):

"It is a complete and useful machine for forming bats
 "of fur on a perforated exhausted cone, without any
 "trunk or channel-way, or other device interposed
 "between the picker-cylinders, rotary brush or other dis-
 "integrating apparatus and the cone on which the bat is
 "to be formed. * * * Without such trunk, channel-
 "way or other device so interposed, the defendant's
 "machine is a perfect one complete in all its parts.
 "*Without it the plaintiff's machine would be use-
 "less.* In one machine the trunk, channelway or other
 "means so interposed is an *essential* means. In the other,
 "it is a *non-essential*. In one machine the trunk with
 "hinged hood controls the current of impelled fur in the
 "direction it should go. In the other other, the current
 "of impelled fur is directed and controlled in the way it
 "should go, by the power of the picking cylinders."

This case in its facts is exactly parallel with that at bar. The Westinghouse patent points out distinctly that it is *essential* to have a segregated or additional passage used to *direct* the train-pipe air to the brake-cylinder, and equally essential to

have an *auxiliary*-valve to control that segregated passageway, and also that the auxiliary-valve is no part whatever, either physically or functionally, of the triple-valve element in the combination, the same being "independent" of the main-valve thereof. In the defendant's, neither the by-passage, nor the auxiliary-valve to control it, are essential nor even useful, nor are they, or any substitute for them, present.

Exactly as in the hat body case, so the defendant here has found, that by using his system of *partitioning the valve chamber* of the triple-valve he can direct the train-pipe air, when required, *through the triple-valve chamber* and control it by the *valves of the old triple-valve*, and that he does not need the additional passageway and auxiliary-valve of the plaintiff's invention nor any equivalent therefor, or any substitute therefor, and, in fact, dispenses with them altogether. It would be difficult to find two cases more closely parallel in the essential facts controlling their decision. (See illustration and comparisons on folder.)

Comparison of the Findings of Fact in the Case at Bar, with Like Findings in Burr vs. Cowperthwait.

Ingersoll, J. in *Burr vs. Cowperthwait*, 4 Blatch (170):

"In defendant machine, there is no guiding trunk, "interposed between the pickers and the cone, to control "and give direction to the sheet of fur carried by the "current of air on to the cone. Neither is there anything "either as an equivalent to the guiding trunk, or in lieu "or in substitution thereof, or for any purpose, interposed "between the pickers and the cone."

Morris, J. in *Westinghouse vs. Boyden Brake Co.* (R., p. 838, folio 1365.)

"I am not satisfied * * * that the poppet valve "22, of the Boyden mechanism is such a (an auxiliary) "valve, for Boyden's poppet-valve 22 does * * * to

chine.

"some extent perform the functions of a main-valve of
 "the triple, as well as the function of Westinghouse's
 "auxiliary quick-action or emergency-valve. * * *
 "Valve 22 will, if the engineer uses his break carefully,
 "do the work of a main-valve, as is *demonstrated*, I think,
 "by the experiments in which the sensitive graduating-
 "valve *ijk* was plugged up. So I take it that defend-
 "ant's valve *ijk* (40) must be held to be the sensitive grad-
 "uating-valve usual in triple-valve devices, since Patent
 "220,556, and the defendant's valve 22 must be held to be
 "the *main-valve*, and that in defendant's mechanism he
 "has been able, by an ingenious arrangement restricting
 "the admission of auxiliary-reservoir air to the triple-
 "valve chamber, to cause the *main-valve* to do both main-
 "valve work when needed, and to do quick-action work,
 "when needed."

If this be true, then the plaintiffs' proposition (on pages 47
 and 48 and repeated several times thereafter on pages 67, 73 and
 78 of their *principal* brief), that "the real 'main valve' of Boy-
 den is the valve *i, j, k*, (40), through which auxiliary-reservoir air
 is admitted for all practical purposes * * * and that stem-
 slide valve (*i, j, k*) is the true 'main valve' *cannot be true*."

The crucial test question was correctly put in the case at bar
 by Judge Hughes of the Court of Appeals (and correctly answered
 in the negative by him) as follows; premising his remarks by
 the statement, that:

"The transmission of train-pipe-air and auxiliary-reser-
 "voir-air simultaneously to the brake-cylinder is a result
 "or function and is not patentable." (Precisely as this
 "Court said of the hat body machine, in *Burr vs. Duryee*
 "and *Gill vs. Wells*, that the '*directing of the fur* from
 "picker to cone' was not the 'mode of operation of the
 "machine,' but the *result* of the use thereof). The mean-
 "(Judge Hughes says) by which this or any result or func-
 "tion is accomplished may be many and various and if
 "these several means are not *mechanical equivalents*,
 "each of them is patentable,' adding: 'The question at

"bar' is whether defendant Boyden's machine in which "the same result is attained (by a novel reconstruction of *the 'triple-valve' itself*), is the *mechanical equivalent* "of Westinghouse's 'attached machine,' non-integral, "segregate and individual consisting of another stem, "another valve, and by-passages peculiar to itself, leading "from the additional valve to the brake-cylinder."

After stating that this precise question was necessarily passed upon by the Patent Office in the grant to defendant of broad claims in his patent therefor, the learned Judge for the fourth circuit added that while such ruling was evidence of great weight though not conclusive, he fully concurred therein, and said:

R., p. 880. "Comparing the two devices apart from the "triple-valve piston in extreme traverse, we are unable to "entertain a doubt that the ruling of the Patent Office "was correct to the effect that Boyden's device was not "the mechanical equivalent of that of Westinghouse. "They seem to us to differ as widely as two devices for "accomplishing the same object can well differ."

"The plaintiff's contention is that Boyden's main-valve 22 is the equivalent of the Westinghouse "auxiliary-valve because, 'Boyden makes it perform the "same purpose.' But Boyden's 'poppet-valve' 22 (substituted) for the slide-valve (which) is the main-valve of "220,556. Boyden's is not an 'auxiliary-valve;' it is "mechanically the original main-valve of the original "triple-valve, and it performs the service which is performed by the main-valve of 220,556. It is not the "mechanical equivalent of (auxiliary) valve 41' (simply "because it performs an additional duty). 'The performance *incidentally* of quick-action service does not make "it an 'auxiliary-valve.' *It is the same valve.* The incidental service is auxiliary, but the valve itself is the "same and unchanged." (R., p. 881).

R., p. 882 "Obviously there is no 'auxiliary-valve,' "independent of the main-valve, in the Boyden device."

Summary of Conclusions.

The defendants do not infringe this patent upon any construction of claim 2, which would not require it to be defeated for want of novelty in its expressed combination of mechanism, or as claiming a mere function or result. In view of the prior art shown in the patent 220,556 and frankly admitted in the patent in suit, Westinghouse invented nothing but the segregated "additional members" making a new "combination" with an old "triple-valve."

Westinghouse proceeded upon the principle of *adding* a separate machine, without disturbing the "triple-valve" element functionally or physically. Boyden abandoned all idea of a separate machine, or a separate valve, or a separate air-passage, and commenced with the idea of using the *same* valves (retaining all their old functions), and the same passage through the triple-valve chamber (it retaining its old function of venting reservoir-air), relying solely upon his new idea and means of effecting differential pressures in the valve-chamber to effect the entrance of train-pipe air when his *main-valve* is opened by a full traverse of the piston to vent reservoir air (as before), for emergency or full-brake pressure work.

The plaintiff's contention may be fairly stated from their brief as follows:—Claim 2, they say, includes by implication (1) an "auxiliary" valve "independent of the main valve"; (2) a passageway capable of conducting train-pipe air to the brake-cylinder, without passing through the reservoir, and (3) a triple-valve, having at least one valve to control the reservoir port, and also a piston whose short traverse actuates the reservoir-air valve and whose full-traverse actuates the train-pipe-air valve.

In order to find infringement by defendants, they assert that the specification of the patent discloses sufficient to justify

calling the following remarkable changes "mechanical equivalents" of the three elements named; viz.:—

I. The "further-traverse" of the piston, while *per se* old and still retained for its primary purpose of actuating the main-valve, *performs a new function*, they say, because it moves an "auxiliary" valve which has been so located in the structure as to be actuated when such usual and old further-traverse occurs; although it is obvious from the mere statement of the proposition, that the new function, in so far as it involves any novelty or patentability (quoad the prior patent 220,556, which had the same movements of piston), is produced by the "combination" of piston **and valve**, and not by the piston alone.

II. That the "passageway" for admitting air "directly" from train-pipe to brake-cylinder, they say, need not be a *separate* passageway, but may be the valve-chamber of the "triple-valve", through which reservoir-air is admitted; although such chamber is old and still performs its old function and is retained for *that purpose*, and so it is said that the triple-valve chamber also performs a new function, to wit, the function of the separate passageway of the patent, which latter may be, under such circumstances, entirely dispensed with.

III. While it is true, they admit, that the auxiliary-valve must be "independent of the main-valve" of the triple, and although it is true that "triple-valves" having both graduating and main valves, of both slide and poppet forms, were well known in the art, and operated by the piston by its preliminary and final movements respectively; yet they say no man may give *one of those old valves* in such *old* structure an additional function—though he do so by means of his own invention of mechanism of a character not even remotely hinted at in the patent in suit.

IV. The "auxiliary" valve, they say, may be on the reservoir side of the piston and therefore enclosed within and a *part of* the "*triple-valve element* of the "combination"; although it is

obvious that such reconstruction of that element would drop out both the "additional members" described *as essential* in the patent in suit.

V. Notwithstanding that the machine would *not* produce quick action with all four of these changes, nor *unless differential pressures were produced by special means, operating at the proper time, in the valve-chamber*, yet differential pressures (they say in their brief but not in the record), and equivalent means to produce them, exist in the Westinghouse device; notwithstanding that the patent does not contain the most remote intimation of such a thing, and not a word of evidence in the record tending in the slightest degree to dispute with Mr. Boyden the pioneership in *valve-chamber* differential pressures and his means to produce them, and notwithstanding the *prima facies* arising from the grant to him of his patent for *such* means, so operating.

This illogical character of the plaintiff's reasoning in order to find so-called "equivalents" leads only to a *reductio ad absurdum*; and suggests the applicability here, of Judge Clifford's remarks in *Burr vs. Duryee*, (see page 572, 1st Wallace).

"The (defendants) machine has not one of the peculiar
 "devices or combination of devices, of the Wells machine,
 "nor any substantial identity with it, unless by substan-
 "tial identity is meant every machine which produces the
 "same effect. These abstract phrases, 'substantial iden-
 "tity,' 'equivalent,' 'mode of operation' etc., are often
 "used in such a vague and equivocal manner, that they
 "mystify and lead many to absurd conclusions who will
 "not distinguish between things that differ. * * Now
 "an infringement involves substantial identity. * * It
 "is a copy, either without variation, or with such varia-
 "tions as are consistent with its being in substance the
 "same thing. * * No one who * * inspects the two
 "machines can aver that they contain the same combina-
 "tion of mechanical devices, or substantially the same,
 "to produce the desired effect."

"its equivalent, used in the one is to be found in the other, nor is its mode of operation the same. The argument used to show infringement assumes that every combination of devices in a machine which is used to produce the same effect, is necessarily an equivalent for any other combination used for the same purpose. This is a flagrant abuse of the term 'equivalent'."

Morris J., comparing the two devices said:

R., p. 844. "It appears from * * patent 360,070 that what Westinghouse meant by 'auxiliary valve,' which is made one of the elements of the first and fourth claims, is such a valve * * *which is independent of and performs none of the functions of the main-valve.*"

R., p. 844. "I have not been able to satisfy myself that Boyden makes use of an 'auxiliary-valve' in the sense in which that term is employed in the specification and and some of the claims of the patent 360,070 now in suit."

After acquitting Boyden of infringement of claims 1 and 4, the court considers and quotes claim 2—

"Westinghouse discovered that he could accomplish this result by * * * cause the piston of the triple-valve to make an **unusual** and **further** traverse, and thereby actuate a valve which opened a port by which train-pipe-air was admitted," &c. See Record, p. 843, folio 1363.

Note. We have quoted above, to show that Judge Morris believed that "the further traverse of the piston" was absolutely new in this structure. There can be no doubt that he so believed, and there can be no doubt that he was wrong, and there can be no doubt that he construed claim 2 as not impliedly containing the "auxiliary-valve" of the other claims, and as he had already said (R., p. 844), that defendants do not so use an auxiliary-valve.

one of them do quick-action work by an ingenious reconstruction of the triple-valve chamber entirely novel with Boyden; he could not have held them to have infringed claim 2 upon any construction of the claim which *included* the "auxiliary-valve" as an element.

Given the admission that the paragraph in the decision of Judge Morris above quoted is founded on an error in fact, and *that the further traverse of the piston was old*, and that in the triple-valve of patent 220,556 such "further traverse" was used for the sole purpose of opening wide the *main-valve*, to admit *reservoir-air*, and that such further traverse would have no effect to vent train-pipe air in the machine of patent 360,070 in suit *unless an auxiliary-valve, is added*, located at the terminus of the traverse of the piston and controlling a *separate* or by-passage leading "directly" to the brake-cylinder, the learned Judge's construction of claim 2 is shown to be erroneous, even on his own reasoning, and for which *on these very grounds stated* he was properly reversed. He was properly affirmed as to the claims 1 and 4, because he said, and correctly held, that an essential feature of the Westinghouse machine *as described in the specification* was an "auxiliary" valve, "which is independent of and performs none of the functions of the main-valve of the triple" and that *defendants had no such valve*.

VI. The plaintiff's contention, as gathered from the *quoted* passage on page 3 of their *supplemental* brief, rests upon their view that claim 2 is to be broadly construed to cover "any valve device" brought into operation by the further traverse of the piston, that will vent train-pipe-air directly to the brake-cylinder.

It is respectfully submitted that this is equivalent to asking this Court to reinstate the erased original and rejected 1st claim. The word "valve" in the above sentence "any valve device" is mere surplusage, and the latter is equivalent to the sentence "a device" for the simple reason that the function stated in both

claims is the admission of air, and any device whose function is to admit air, must admit it through an opening or port, and any device controlling an air opening or port is, in the technical sense, a valve. The words "further traverse" in the 2nd claim do not distinguish it, in substance, from the original erased 1st claim, (which did not contain these words), for the reason that both claims expressly include as an element a "triple-valve", such as 220 556, which contains *a piston having both a preliminary traverse and a final traverse in its usual operation*, the former opening its graduating-valve and the latter opening its main-valve. It would be both illogical and contrary to the doctrine of interpretation of patents, to hold that a claim which expressly includes a well-known element specifically referred to as 220,556, having a piston with two well-known movements, might for the sole purpose of distinguishing it from some other claim, be construed as including such an element *altered to have only one of such movements, i. e., a preliminary or partial traverse and never a full one.*

But the plaintiffs contend in their brief (though not in the patent) and *must* contend in order to find identity in any respect whatever with the defendant's device, that the (Westinghouse) invention may be stripped of what they call non-essentials, to wit, a *segregated* passageway, and that, while it must have an auxiliary-valve, such valve need not be physically auxiliary, as shown in the patent, but may be integral *and one and the same* with the main-valve of the triple-valve element; the "gist" of the invention, as they allege, being the provision of a valve, whether it be one of the triples or not, that will admit train-pipe-air, provided it be brought into operation by the "further traverse" of the piston. Aside from the proposition advanced by the defendants, which is incontrovertible and has not been answered by the plaintiffs, that even such a broad construction would be useless and inoperative to produce the result, *without a reconstruction of the valve-chamber* (which the Westinghouse patent

does not teach but which the Boyden patent *does* teach for the first time), there are several reasons why the contention of the plaintiffs is unsound.

First. The plaintiff's contention admits that there must be a passageway for train-pipe-air directly to the brake-cylinder. It will not do to say that the triple-valve-chamber may be such a passageway as is contemplated in the plaintiff's patent. If the latter disclosed for the *first time* a triple-valve-chamber and a separate passageway, one for reservoir-air and the other for train-pipe-air, of course it would not necessarily constitute non-indentity to combine the two in one, but where the reservoir-passage existed before, and where it still exists, and is still used for the same purpose that it was used before, the plaintiff's contention is equivalent to dropping out entirely his passageway when he seeks a construction which includes the old passageway to convey *both* airs to the brake-cylinder.

Second. His contention that the further traverse of the piston contacting with and moving a specifically new valve (not an old one already in the device, but with an added function) is "making the piston on its further traverse perform an added new function," is a perfectly correct contention, and that is exactly the invention patented by Westinghouse, in connection with the separate passageway controlled by such valve. But the further traverse of the piston, *not* contacting with, *but carrying at all times* the old *main-valve*, which is *not* an added valve, but is and always was a part of the "triple-valve" element, and still remains in the triple-valve element to perform its old function of admitting reservoir-air on *the same final traverse* of the piston, is not making the piston (in defendants' apparatus) perform a new function in its further traverse, *simply because, by reconstructing the valve-chamber, such old MAIN-VALVE now also performs an additional function.*

Third. The plaintiff's contention, that the defendants' main-valve, is an auxiliary-valve merely because it performs an additional function on the same further traverse of the piston, by

which its main-valve functions always were performed in the old art, is obviously an argument not that defendant's main-valve is the the *mechanical* equivalent of the plaintiff's auxiliary-valve to perform the new purpose, but that it is the *functional* equivalent.

Judge Hughes states the proposition more neatly in the following language, in his opinion (R., p. 881):

"The performance incidentally of quick action service
 "does not make it (the main-valve) an auxiliary valve. It
 "is the same valve. The incidental service is auxiliary
 "but the valve itself is the same and unchanged."

Non-identity, as a Finding of Fact by Three Tribunals.

Three times by three tribunals in succession, (the Patent Office, the Circuit Court, and the Court of Appeals), have the plaintiffs in the case at bar been told that the defendants' novel, admirable and ingenious mechanism, is the "triple-valve" of the prior art improved as described in Boyden's 1892 patents and now operating to vent both such airs by means of novel changes entirely in the *valve-chamber*, and without any changes in, additions to, or subtractions from, its *old valves* or the old *double traverse* of its piston; and that it does *not* contain the "additional members" or any mechanical equivalent therefor, which Westinghouse added to a "triple-valve" having two valves already and a piston having two traverses, to make up his new "combination", as he calls it, in his letter to the Patent Office.

In view of the burden of proof being on the plaintiffs under the single issue of fact involved, and in face of the *prima facie* presumption against the proposition arising from physical differences in the machines, and in the face of a grant of a patent to defendant on the application in which this precise question of fact was passed upon, and in the face of two decisions by the lower Courts, both finding against the plaintiffs' aforesaid proposition,

it is preposterous to say that this Court should, on the mere ipse
fact of counsel in the brief (aided by their pictorial illustrations
of *imaginary* structures in their brief, but not in the record,
and by obvious misnomer of the vital parts of the machine,
and by obviously misleading coloring of such parts) say that
the plaintiffs have discharged their burden of proof beyond any
reasonable doubt, or will upon such showing reverse the find-
ing of fact by three tribunals in succession, all in perfect
accord with each other, on this most vital and decisive ques-
tion of non-identity.

Respectfully submitted,

HECTOR T. FENTON,

Of Counsel for Defendants.

February, 1897.

BRIEF OF RE-ARGUMENT

—BY—

LYSANDER HILL.

ON BEHALF OF THE BOYDEN BRAKE COMPANY,

“Straight” and Automatic Air Brakes.

As the straight and automatic air brakes have been fully described previously, (pp. 3 to 8 in my former brief), I will only discuss the old triple-valve of the automatic air brake, and then show what Mr. Westinghouse and Mr. Boyden respectively invented and combined with the old triple-valve, by which the train-pipe is vented under each car of its air pressure in order to accomplish the result of quickening the serial application of the several brakes throughout the train.

Two Distinct Old Forms of Triple-Valves.

There are two distinct forms of “triple-valves” known to the air-brake art—distinct not in producing different results or having a different mode of operation, but only in their mechanical construction. The one form employs the *sliding* type of main-valve, while the other employs the *poppet* type of main-valve. These two old forms of triple-valves are represented by the cuts opposite ~~the following page.~~

Comparison of the Two Old Forms.

PASSAGES OR CONNECTIONS.

In both forms you will perceive there are passages which connect with the train-pipe; with the auxiliary reservoir; and with the atmosphere.

PISTONS.

In both forms there is a piston whose function is to actuate the different valves in the triple-valve structure

THE OLD SLIDE VALVE FORM OF TRIPLE VALVE.

AUXILIARY RESERVOIR CONNECTION.

AUXILIARY
RESERVOIR

In both structures there are four valves—Feeding-in Valve, blue; Graduating Valve, yellow; Release Valve, green, and Main Valve, black. The valves all functionate as Triple Valves, and it follows that if said valves are "Triple Valves" in the *slide* form, they are also Triple Valves in the *Poppet* form. The piston in both has a "preliminary traverse" and a "further traverse," but the latter is not shown in the *Poppet* form.

Cuts of the Two Large Models Used During the Reargument.

THE OLD SLIDE VALVE FORM OF TRIPLE VALVE.

THE OLD POPPET FORM OF TRIPLE VALVE.

In both structures there are four valves—Feeding-in Valve, blue; Graduating Valve, blue; Release Valve, green, and Main Valve, black. The valves all functionate as Triple Valves, and it follows that if said valves are "Triple Valves" in the *slide* form, they are also Triple Valves in the *Poppet* form. The piston in both has a "preliminary traverse" and a further traverse," the two traverses being old, and used since 1873.

FEEDING-IN-VALVE.

In both forms there is a feeding-in-valve (colored blue), whose function is to control a port by which compressed air is admitted from the train-pipe to the auxiliary-reservoir, where it is stored ready for use.

GRADUATING VALVE.

In both forms there is a sensitive graduating-valve (colored yellow), whose function is to control a *small* port through which the air passes slowly or in graduated amounts from the auxiliary-reservoir to the Brake-cylinder, to *slowly or partially* apply the brakes for ordinary service stops.

RELEASE VALVE.

In both forms there is a release-valve (colored green), whose function is to open a port by which air is discharged from the brake-cylinder to the atmosphere, to release the brakes.

MAIN VALVE.

In both forms there is a main-valve (colored black), whose function is to control a *large* port through which the air passes quickly and fully from the auxiliary-reservoir to the brake-cylinder, to quickly and fully apply the brakes for emergency stops.

SUMMARY OF PARTS OF BOTH FORMS OF OLD TRIPLE-VALVE.

First: Each structure has three passages with like connections.

Second: Each structure has a piston.

Third: Each structure has a feeding-in- valve (blue).

Fourth: Each structure has a graduating-valve (yellow).

Fifth: Each structure has a release-valve (green).

Sixth: Each structure has a main-valve (black).

Operation of the Old Triple-Valve.

TO CHARGE THE BRAKES.

In both old structures the air passes from the train-pipe, shifts the triple-valve piston to the left, then passes through a feeding-in-valve (blue) into the valve-chamber and then to the auxiliary-reservoir.

TO SLOWLY AND PARTIALLY APPLY THE BRAKES.

In both structures when a *small* amount of air is discharged by the engineer from the train-pipe, the pistons make their "preliminary-traverse," and thereby open the graduating-valves (yellow), permitting the auxiliary-reservoir air to slowly, or in graduated amounts, pass to the brake-cylinder to slowly or partially apply the brakes.

RELEASE OF THE BRAKES.

In both structures when the maximum pressure is restored by the engineer in the train-pipe, the pistons are moved to their normal position, to the left, thereby opening the release-valves (green) and discharging the air from the brake-cylinder to the atmosphere and releasing the brakes.

TO QUICKLY AND FULLY APPLY THE BRAKES.

In both structures when a *large* portion of air is discharged by the engineer from the train-pipe, the pistons make their "further" or "full traverse," and thereby open the main-valves (black), permitting the auxiliary-reservoir air to *quickly* and *fully* pass to the brake-cylinder and apply the brakes in the shortest time possible and with the maximum pressure.

Therefore the operation of both these old triple-valve structures is the same; they both produce the same results; they both contain pistons which functionate to operate the different valves, and they both contain the same number of valves (four) which functionate precisely the same in their individual capacity, and as a whole. The only difference

between them is in the mechanical construction of their corresponding valves. In one the *main-valve* is of the SLIDE FORM, whereas in the other the *main-valve* is of the POPPET FORM, but in both the main-valve governs the large or main port between the auxiliary-reservoir and brake-cylinder, and is opened by the "further traverse" of the piston. Therefore, I respectfully submit that if the *slide-valve* (black) is the main-valve in one structure, the *poppet-valve* (black) is also the main-valve in the other structure.

These two triple-valve structures are old, all the patents on them have expired, they are public property and any one can make or sell them, or either of them, without being held liable under any patent.

Complainants' and Defendants' Inventions.

COMPLAINANTS' DEVICE.

[See Cuts opposite following page.]

Mr. Westinghouse took the *slide form* of triple-valve, the structure just described, to which he arranged an "auxiliary-valve device" (colored red), shown in the lower cut opposite, and which is made visible in the small models which your Honors have, by turning down the cover concealing the additional device. This "auxiliary-valve device" consists of:

First: By-passages 43 and 46, whose function is to vent the train pipe under each car, whereby the pressure of the train-pipe is quickly reduced and thereby the application of the several brakes throughout the train made nearly simultaneous.

Second: A valve 41, *auxiliary* to this triple-valve. The function of this new valve is to open and close the said by-passage whereby the venting of the train-pipe air is controlled.

Third: In giving to, or endowing, the old "further traverse" of the piston with, a *new or additional function*, to wit, opening the new auxiliary-valve 41.

OPERATION OF COMPLAINANTS' DEVICE.

With this new device added, the old slide-valve form of triple-valve operates as previously described (see upper cut opposite), but when the piston of the triple-valve makes its "further traverse" to perform its old function of *opening* the main-valve (black), to permit the auxiliary-reservoir air to pass to the brake-cylinder (as shown by the red line, see lower cut opposite), said piston now performs the new function—that of *opening* the additional valve 41 (red), which vents the train-pipe air to the brake-cylinder through the additional passage 46 (as shown by the blue line), which has the effect of quickening the application of the brake on the next car, and so on throughout the train, which results in applying all the brakes of the train nearly simultaneous. Thus, in the complainants' structure, *two* valves are employed, and the piston on its *further traverse* required to perform a new or additional function.

DEFENDANTS' DEVICE.

[See Cuts opposite following page.]

Now, Mr. Boyden took the old *poppet form* of triple-valve just described and perceived, what no man living before him did, that this old triple-valve possessed latent powers that were capable of venting the train-pipe without an additional machine or another valve of any kind, and moreover, that the *further traverse* of the piston need not be called on to perform a *new* function or to do anything more or less than it always had done, and Mr. Boyden's conception was reduced to practice by the most ingenious and simple means imaginable; namely, he merely divided the valve-chamber C from the piston-chamber D by inserting a partition 9.

Before this simple change was made the structure was an old plain triple-valve, public property, capable of doing only old triple-valve work. Now, with the *partition* added, it continues to do the same work as before, but it will now also vent the train-pipe. Your Honors will perceive that no passage has been

THE OLD SLIDE FORM OF TRIPLE VALVE, Incapable of Quick Action.

Complainants Structure.

The Old Slide Form of Triple Valve plus the Complainants Second Machine, consisting of an Auxiliary Valve 41, and By-passage 46, shown in Red.

It is therefore seen that the Complainants take the slide form of Triple Valve and combine with it a second machine through which the train-pipe air is vented, and endow the piston with a new function, that of operating the second machine.

Incapable of Quick Action.

**The Old Poppet Form of Triple Valve, made Capable of Quick Action
by inserting Boyden's Partition 9.**

It is therefore seen that Defendants take the old Poppet form of Triple Valve and make it vent the train-pipe air by simply inserting the Partition 9 without requiring a second machine of any kind, or requiring the piston to perform a new function.

added for train-pipe air to pass through; no new valves have been *added* nor does the *piston* perform any new function. The only change made is the insertion of the partition 9.

OPERATION OF DEFENDANTS' DEVICE.

Your Honors will recall that, as a plain triple-valve, when the brakes were to be *quickly* and *fully* applied, the piston of this same structure made its "further traverse," and fully opened the main-valve port for the auxiliary-reservoir air to pass to the brake-cylinder (as shown by the red line, (see upper cut opposite). Now, when the partition 9 is in place, that old operation of the piston and the main-valve is performed just as before, but the partition serves to partially confine the auxiliary-reservoir air in the piston-chamber D and thereby prevents that air from freely passing to the valve-chamber C, so that the previously existing 70 lbs. pressure in the valve-chamber is instantly discharged through the wide-open port of the main-valve and said pressure is thereby reduced to about 5 lbs., whereupon the air-pressure from the train-pipe, at 55 lbs., enters the chamber C (shown by the blue line, see lower cut opposite), and commingling with the auxiliary-reservoir air (shown by a red line), is vented through the *main-valve port*, which results in the quickening of the brakes on the following car. Thus in the defendant's device only *one* valve is used to vent the two airs, and that the old main-valve (black) of the triple-valve, and the piston is *not* required to perform a *new function*.

It is therefore seen that in defendants' structure the only alteration in the old triple-valve is the *insertion of the partition 9* which enables the old triple-valve to vent the train-pipe air.

Defendants' structure therefore does not employ :

First : Any by-passage.

Second : Any auxiliary-valve.

Third : Nor require the "further traverse" of the piston to perform any *new* or *additional* function.

All three of these are the very essence of, and are absolutely required in the complainants' structure. As not one of them is to be found in defendants' structure, evidently, that structure is not the same as complainants.

Comparison of Complainants' and Defendants' Devices.

In the Westinghouse device the old element (triple-valve) is provided with a new and an additional valve device that *functionates* to vent the train-pipe air. The new device is actuated by the "further traverse" of the old piston. Thus, as stated in Claim 2, the piston "*by a further traverse, admits air directly from the main air-pipe to the brake-cylinder.*"

In the Boyden structure no new device is added to the old triple valve element to vent the train-pipe, or to be actuated by the "further traverse" of the old piston. The device Boyden added *functionates* to suddenly reduce the pressure in the valve-chamber, and the train-pipe air then enters said chamber and flows out through the *main-valve* port, which is, and always is, wide open when making an emergency stop with *any* form of triple-valve. In Boyden's device it is true the train-pipe air is admitted to the brake-cylinder *at the moment* the "further traverse" of the piston is made, but this result is produced *not* "by the piston" as in complainants', but by the partition 9.

In other words Mr. Westinghouse's *new device* (the auxiliary-valve 41) *functionates* to do the *new thing* by a preceding action of the old element (the piston), whereas Boyden's *new device* (the partition) *functionates* to enable the *old element* to do the *new thing*.

Certainly here is a radical difference between two inventions to accomplish the same result. The Court of appeals in comparing them remarked, "they seem to us to differ as widely from each other as two devices for accomplishing the same

result can well differ," and this conclusion of that Court is true for the following reasons:

- (a) Westinghouse's added device (the auxilliary-valve) functionates to vent the train-pipe.

Boyden's added device (the partition 9) functionates only to restrict the flow of auxiliary-reservoir air.

- (b) Westinghouse's added device (the auxiliary-valve), is operated by the "further traverse" of the piston.

Boyden's added device (the partition 9), is not operated by the further traverse of the piston, or otherwise, for it remains stationary.

- (c) Westinghouse endows the triple-valve piston with a new function, to wit: opening the new auxiliary-valve to admit train-pipe air.

Boyden does *not* endow the triple-valve piston with any new functions, or call on it to do any thing more than it always did,—it simply opens the same old valves.

With these great existing differences, we submit it is not possible for the device of the defendants to come within any claim the complainant's patent may have.

Comparison of the Two Devices with Claim 1, 2 and 4, Alleged to be Infringed.

Claim 1 is as follows:

"In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, a triple valve, and an *auxiliary-valve* device, actuated by the piston of the triple-valve and independent of the main-valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake-cylinder, substantially as set forth."

Now, all the elements named in this claim are old in automatic air-brakes except the "*auxiliary-valve*." In the defendant's device no "auxiliary-valve" is employed, as the old main-valve, black, is used to vent the train-pipe are at the same time

it is performing its old function of venting the auxiliary-reservoir air. Therefore there is no infringement of claim 1, as the only new element in that claim is not found in defendant's device.

Claim 4 is as follows:

"The combination, in a triple-valve device, of a case or chest a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary-reservoir and a brake-cylinder and to the atmosphere, respectively, and an *auxiliary-valve* actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, substantially as set forth."

This claim is substantially like claim 1, all its elements being old except the "*auxiliary-valve*," and defendant's device not having an auxiliary-valve, is no infringement of that combination for the same reason that applies to claim 1. The Circuit Court and the Court of Appeals for the Fourth Circuit both held that neither claims 1 nor 4 are infringed by the Boyden device.

Claim 2 is as follows:

"In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which, by a further traverse, admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth."

Owing to the ambiguity of the language used in this claim it is subject to several different constructions.

AMBIGUITY OF CLAIM 2.

The ambiguity arises from the fact that the combination named in the claim was old. It is simply the old triple-valve device of patent 220,556 and other old triple-valve patents. The two traverses were also old, and it was old to apply the partial traverse for graduating and service stops, and the full traverse for emergency stops.

The only new thing referred to in the claim is indicated by the words: "A piston * * * which, by a further traverse *admits air directly from the main air-pipe to the brake-cylinder.*" The "piston" is the mechanical element here named as the actor; and the words "admits air directly from the main air-pipe to the brake-cylinder," specify merely the function or act performed by the piston. But a *function* is not patentable; and hence the claim must rest squarely on the *piston*, which is said to perform the function.

The piston, itself, however, is old, being nothing more nor less than the piston shown in Fig. 4 of patent 220,556 (R., p. 762); hence, a claim based on the *piston* as the alleged element of novelty cannot stand. The entire combination named in the claim, including the piston, is old; and in the old structures the piston had the same movements that it has here, and under precisely the same conditions. This old combination cannot lawfully be claimed here; and yet, if we read the claim literally, it is the only mechanical thing that *is* claimed here. How, then, shall the claim be construed?

In considering this question, the first thing which arrests our attention is the fact that the combination named in the claim, including the piston, *does not perform the function alleged of it*, and cannot perform it without the aid of other important instrumentalities not mentioned in this claim, viz., the auxiliary-valve 41 and by-passage 42, 43, 46. It did not perform said function, in patent 220,556, because of the absence of these additional instrumentalities; and it does perform it in patent

360,070 because of their presence. They are, therefore, absolutely vital to any proper legal construction of the claim, and must, in some form or other, be construed into the claim; otherwise, the claim is invalid, for the same reason that Morse's eighth claim (*O'Reilly vs. Morse*) was held invalid.

CONSTRUCTION OF CLAIM 2.

We can conceive of only two ways in which the *necessary additional elements* can be construed into the claim, viz., (1) by construing it so broadly as to cover *all possible additional means* which will enable the specified combination to produce the specified result; and (2) by construing it to cover, as implied elements of the combination, *the auxiliary-value 41 and its by-passage*.

Can there be any doubt as to which of these two constructions should be adopted? We think not. The former would bring the claim directly within the inhibition of this Court in *O'Reilly vs. Morse*, 15 How., 62; *Burr vs. Duryee*, 1 Wall., 570, and *The Incandescent Lamp Case*, 161 U. S., as well as under that of the leading English case on this subject, *Neilson vs. Harford*, 1 Webster's Pat. Case, (cited and commented on at length in *O'Reilly vs. Morse*), as being for a "principle," or, in other words, for all possible ways of accomplishing the result, whether they were known to Mr. Westinghouse, or included within the means invented by him, or not. Such a construction would make this Court say, in substance: "The combination that is named in the claim does not do the work; something must be added to it to enable it to accomplish the function; and we will, therefore, construe the claim as covering everything that *can* be added to it for that purpose, whether like the means which Mr. Westinghouse invented or not, and whether now known, or discoverable only by future effort." This Court will never give such a construction to the patent law; for it would overthrow every decision on the subject made in this country or England during the last fifty years. If Sawyer & Man, who

broadly claimed "carbonized *vegetable* fibre" for incandescent lamp filaments (*The Incandescent Lamp Case*, 161 U. S.), were not allowed to cover carbonized *bamboo* fibre, because they had no knowledge of its superior qualities when they procured their patent, how can Mr. Westinghouse be allowed to cover, by the indefinite language of his second claim, devices which he did not invent, and of whose structure and mode of operation he was totally ignorant? The doctrine of *The Incandescent Lamp case* is, that a patentee can cover only what he has invented or discovered, and that if his claims, by the use of broad generalizations, reach out beyond his real discovery, they must be limited back to it by construction. What Mr. Westinghouse invented and added to the old triple-valve, and described in his patent as new, was the auxiliary-valve 41 and its by-passage; and if his second claim reaches beyond this, it should be limited back to it, as was done in *The Incandescent Lamp Case*. This fully protects his rights, and leaves other inventors to benefit the public by discovering other and different means for accomplishing the result.

We are, therefore, constrained to adopt the *second* of the two constructions, which can be given his claim 2, viz., to read the claim as embracing the auxiliary-valve 41. This corresponds to the description contained in the specification, and gives effect to the words "substantially as set forth," found at the end of the claim. It is consistent with the statement of the specification, that the triple-valve

*"is not, therefore, saving as to the structural features
 "by which it performs the further function of effecting
 "the direct admission of air from the main air-pipe to
 "the brake-cylinder, as presently to be described, claimed
 "as of my present invention."* (R., p. 784 L. 12.)

The Patent Office Record Shows that Mr. Westinghouse Himself Placed this Construction on Claim 2.

Mr. Westinghouse's attorney, in his letter, when arguing for the allowance of this second claim, said that the "applicant does not seek to broadly claim a device for admitting air directly from the main air-pipe to the brake-cylinder," but that "when, however, the triple-valve *is provided with an auxiliary-valve, operated by its piston*, which performs a new function, additional to that of the triple-valve as previously employed, it is believed that *such combination is wholly novel*." (R. p. 718, L. 41.) It is consistent with the admission of complainants counsel, p. 41 of their brief, used in the Circuit Court of Appeals, at Richmond, where they said that the "quick-action attachment, consisting of an air-conduit or passage-way, directly from the train-pipe connection to the brake cylinder, *and a valve to control it*,
 * * * *is so made the subject matter of every claim in controversy as to give character and effect thereto*, and render the scope of the claim coextensive with the invention." It agrees with the decision of Judge LACOMBE, in the New York case, who construed the second claim as like the first, but more limited—meaning that the first claim covered the auxiliary-valve, whereas, the second claim covered it only when used on the *final traverse* of the piston—but reading the auxiliary-valve into all of the claims.

So construed, the claim is not infringed by the Boyden device, which has no auxiliary-valve or by-passage, but, on the contrary, has a entirely novel mode of operation, whereby the work is performed by the old plain triple-valve without the aid of anything added by Westinghouse.

THE COMPLAINANTS' CONSTRUCTION OF CLAIM 2.

Complainants' counsel, on p. 22 of their brief at the former hearing in this court, suggested that Westinghouse "availed himself of the capacity of the triple-valve piston for varying

lengths of travel," "to perform a new function," viz., by its final traverse to *open a passage directly from the train-pipe, and thereby charge train-pipe air directly into the brake-cylinder*; and they seem to think that if the second claim be construed as covering the performance by the piston of this "new function," the defendants will necessarily infringe the claim. But in this they are in error, as we will now proceed to demonstrate.

In their assumption that the *Westinghouse piston* performs a new function, they are correct. Prior to the invention of the patent in suit, that piston, in making an emergency-stop by the old triple-valves, performed one function, namely, that of opening the *main-valve* to admit *auxiliary-reservoir air* to the brake-cylinder. In the device of the patent in suit he retained that old function and added the new one of opening also the *auxiliary-valve* to admit *train-pipe air* to the brake-cylinder, thus it now performs two functions.

But, in making an emergency-stop with the Boyden device, the piston performs only *one* function, to wit: its old and well-known function of opening the *main-valve* to admit auxiliary-reservoir air to the brake-cylinder, common to all the old triple-valves. Having performed that function, the piston ceases to act. Now, *that* function does not admit train-pipe air to the brake-cylinder—if it did, the old triple-valves would be quick-action triples, and there would have been no occasion for the new invention of Mr. Westinghouse—and if it did, the Boyden device *with the partition 9 removed* would be a quick-action triple, which it admittedly is not. It is clear, therefore, that opening the main-valve is not the *cause* of admitting train-pipe air. The opening of the main valve merely creates a passage-way from the valve-chamber to the brake-cylinder—the *old passageway*, always created in the same way by the main-valve of the old triple-valves when making an emergency stop. When this passageway is thus created, the train-pipe air will not enter the valve-chamber and flow to the brake-cylinder, *unless*

the pressure in the valve-chamber can be, in some way, reduced far below that of the train-pipe. Now, what causes the pressure in the Boyden valve-chamber to be reduced below the train-pipe pressure, when making an emergency stop? Not the opening of the main-valve, because, when the partition 9 is removed and the main-valve opens to its full extent, in making an emergency stop, the pressure in the valve-chamber *does not* reduce below that of the train-pipe. What, then, is it that reduces the pressure of the valve-chamber to a greater extent than the train-pipe pressure? We answer: Mr. Boyden had the genius to perceive that when the main-valve was open to admit auxiliary-reservoir air to the brake-cylinder, as in all the old triple-valves when making an emergency stop, *if he could choke off the auxiliary-reservoir air from entering the valve-chamber so fast as it discharges therefrom to the brake-cylinder*, he would thereby obtain such a reduction of pressure in the valve-chamber as would enable the train-pipe air to open the check-valve 26 and flow to the brake-cylinder together with the auxiliary-reservoir air; and he inserted the partition 9 to *choke off the auxiliary-reservoir air, and thereby accomplished quick action* by the venting of train-pipe pressure on each car. In this act the main-valve simply performs its old function of opening the passageway; while the partition 9 performs a new function—that of choking off the auxiliary-reservoir pressure from the valve-chamber. When this new function of the partition is superadded to the old one, then quick action takes place; and only then. The new function performed by the piston in the device of Mr. Westinghouse is not a choking-off function, and is not performed upon the auxiliary-reservoir air flowing *into* the valve-chamber; on the contrary, it is a valve-opening function, and is performed upon a sliding piece of metal arranged in the side wall of the drain-cup. The two new functions of Westinghouse and Boyden are, therefore, absolutely different from each

other—nothing could be more so; they are performed upon different materials, and they are performed by different agencies—the one, by the final traverse of the piston acting on the new auxiliary-valve; the other, by the motionless presence ~~of~~ of the obstructive partition having *nothing to do with the piston*, and acting only on the air-pressure in the valve-chamber.

It follows, as before stated, that if we adopt the legal construction of the claim, as suggested in the brief of complainant's counsel, to wit: That it covers all triple-valve devices in which the piston performs the *new function* of the Westinghouse piston, still the defendants' device would not infringe the claim, because (1) its piston performs no *new function*; (2) only the partition 9 performs anything like a new function in the Boyden device; and (3) that function is totally different from the new function of Westinghouse piston, and produces the result by a totally different mode of operation. **Given an old triple-valve, Westinghouse adds a new air-passage, and a new valve to control it and endows the movement of the piston with a new function; given an old triple-valve, Boyden adds a new stationary partition to reduce the pressure in the valve-chamber, but does not endow the movement of the piston with a new function.** How could two inventions be more totally different from each other than these two? And, how can any valid claim be drawn on the one that will cover the other? The vice in the theory of complainants' counsel, relative to claim 2, lies in its ignoring the fact that Westinghouse's piston, in making its "further traverse," performs *two* functions (the old and the new), while Boyden's piston performs only *one* (the old); and that Boyden has discovered how to take advantage of this performance of the piston's *old* function by choking off the access of auxiliary-reservoir pressure to the valve-chamber, and *thus* causing the train-pipe air to enter that chamber and pass to the brake-cylinder. The question is not whether they both effect quick action, for that is only the general result, and not patentable to either; but it is, *how* they

effect it; and, as we have seen, they do the work by entirely different devices and different methods.

Therefore, even if the Court construes the ambiguous language of claim 2 to mean just what the complainants contend for, namely, the "further traverse" of the piston performing a *new function*, by which the train-pipe air is admitted to the brake-cylinder, the defendants' device cannot be an infringement of that claim, as in it the piston *does not* perform a *new function*. But this construction of complainants is not permissible in view of the rejection of claim 2, and its subsequent allowance, as stated in applicant's letter to the Patent Office (R., p. 718, L. 41), that when an "auxiliary valve" is used with the old triple-valve piston, *that* is a novel "combination."

Claim 2 Construed as Including the Double Traverse of the Piston, a Passage-Way and a Valve.

Claim 2 construed as set forth on p. 89 of complainants brief for "(1) the double traverse of the piston, (2) a passage, or way of access directly from the train-pipe to the brake-cylinder and (3) a valve which controls the passage."

This statement of complainants counsel as to what constitutes the "*essentials*" of the Westinghouse structure, we agree is correct as far as it goes, but we add that any statement of "*essentials*" must be *consistent* with the specification. On this important point (*essentials*) the specification is clear and explicit and shows that what complainants' counsel call the "*essential features*" to wit, the passage for train-pipe air and the valve, are expressly stated to be "additional members" to the triple-valve. The specification of the patent says: (Rec. p. 785 last line.)

"the triple-valve accords * * * with my letters-patent * * * 220,556, and in "order that it may perform the further functions requisite in the practice of

"my present invention, it is provided with certain *additional members*, which will now be described. For the purpose of effecting the admission of air directly from the main air-pipe to the brake-cylinder when it is desired to apply the brakes with great rapidity and full force, an auxiliary slide-valve 41 (the red valve) is connected" etc., and a separate passage 46 to the brake cylinder is provided. It is therefore submitted that the "essentials" must consist of "additional members" *added* to the *old* triple-valve.

We do not contend that claim 2 should be limited as complainants say "by a *slavish* adoption of the *identical* instrumentalities" described in the specification, on the contrary we say construe the claim as broadly as possibly consistent with the specification of the patent, to wit: a valve and passage-way of any form or character which are "additional members" to the *old* triple-valve. These are what Mr. Westinghouse describes as his new devices and claim 2 so construed will be co-extensive with his invention.

Defendants device does not infringe claim 2 thus construed because the valve and passage employed are *old* triple-valve parts, and in no sense "additional members" of the triple-valve, and therefore not within the claim 2 under this construction.

Complainants' Contentions Answered.

COMPLAINANTS' CONTENTION AS TO DEFENDANTS' MAIN-VALVE 22
BEING THEIR AUXILIARY VALVE.

The complainants realizing that they are compelled to find an auxiliary-valve in the defendants' devices try to do so by specious arguments and theories, contending that the defendants' OLD POPPET FORM of main-valve is the new AUXILIARY-VALVE of the patent in suit. But this Old Poppet Valve (Black) was in triple-valves as early as in 1873. (See Patent No. 141,685, R-, p. 736). Its function therein was to admit the auxiliary-reservoir air to the brake-cylinder, a function

which it still performs in the defendants' device; but now, because the same valve admits the train-pipe air while it is admitting auxiliary-reservoir air, they say it becomes a new and auxiliary-valve. The Court below, in defining this valve, stated:

"In the original triple-valve it performed no other service than admitting auxiliary-reservoir air into the brake-cylinder; in Boyden's device it continues to perform that service, and is made incidentally instrumental in allowing the passage of train-pipe air. The performance incidentally of quick-action service does not make it an auxiliary-valve. It is the same valve. The incidental service is auxiliary, but the valve itself is the same and unchanged." (R., p. 881.)

And that statement of fact is obviously absolutely true.

WHY IT IS THE MAIN-VALVE.

In all triple-valves used since 1873 to the present time the main-valve thereof is located on the auxiliary-reservoir-side of the piston, so that when closed, it prevents auxiliary-reservoir air from passing to the brake-cylinder, and when opened admits the auxiliary-reservoir air to the brake-cylinder. Now, this is just where the defendants' POPPET-VALVE 22 (black) is located, and is just what it does when closed and what it does when opened. It was the MAIN-VALVE before the partition 9 was put in the device, and the insertion of the partition cannot make the MAIN-VALVE that existed before in the structure an auxiliary or additional valve, and this fact has been three times so decided.—First, by the Patent Office (R., p. 815, L. 23); second, by Judge Morris, of the Circuit Court (R., p. 845, L. 2); and, third, unanimously by the Circuit Court of Appeals for the Fourth Circuit (R., p. 881, L. 40).

COMPLAINANTS CONTEND THAT THE DEFENDANTS' PARTITION 9 IS FOUND IN THEIR STRUCTURE AND IS OLD.

This contention is absolutely untrue, as the complainants' structure does not contain a partition to divide the valve chamber C from the piston chamber D. If the complainants' device

has such a partition, why the necessity of the "additional members," consisting of a by-passage and auxiliary-valve? And why is it that the piston therein has to do more work, by performing an additional function, than it did before? No; Boyden's partition is not found in complainants' device.

The complainants are trying to deceive the Court by a specious argument that the port 35 and the end of the main-valve 14 is the equivalent of Boyden's partitions; but are those things of complainants *located* between the piston-chamber D and valve-chamber C? No. Or, do those things make the triple-valve *per se* vent the train-pipe in the complainants' device? No. The fact is, that counsel for complainants realize the controlling character of defendants' *partition* 9, and are simply trying, by specious arguments, to make the Court believe that it is not new with Boyden, and that it is found in complainants' structure.

BOYDEN'S PARTITION NEW.

As to its being, new, no one can point to a triple-valve in the whole prior art that contains *such* a partition, one that will confine the air in the piston-chamber D and cause the air-pressure to be *lowered* in the valve-chamber C, so that the triple-valve will vent the train-pipe air by such an operation. This partition 9 was absolutely new with Boyden. It was *broadly* patented to him on his application, dated September 30, 1889, (R., p. 799, L. 5,) *before December* 12, 1889, *when this suit was brought*; therefore, their allegation on page 5 of their brief is untrue.

ALL TRIPLE-VALVES HAVE SOME KIND OF PARTITION.

It is true all triple-valves have partitions; the piston is a partition, all the valves are partitions, the dividing walls are partitions, but no partition operating like Boyden's is found in any prior triple-valve or in any structure that complainants have; a partition that will endow the triple-valve with capabilities to vent the train-pipe *without adding any valves* or changing its old function, and not requiring its piston to perform a

new function or to do one thing more or less than it always did. That kind of *partition* is nowhere found in the whole art except in the Boyden invention.

CREDIT DUE MR. BOYDEN.

To Mr. Boyden is due the credit that the art is advanced one more step by the invention of a partition inserted in the triple-valve chamber by which additional valves and passages are dispensed with and the prior quick-action structure is simplified one-half, whereby fewer parts are required to be kept in order, fewer parts to be replaced, and a greater certainty of action when the apparatus is called on to prevent the loss of life and the destruction of property.

THE CAPABILITY OF BOYDEN'S PARTITION.

That partition is a very simple and small thing, but its capabilities are great; by it the latent powers of the triple-valve are made available; by it the old emergency application of the triple-valve is changed; by it the *additional* member of the patent in suit or of a "second machine" of any character are entirely dispensed with and the piston not required to do additional work.

In the Boyden structure the feeding-in-passage from the train-pipe through the piston to the valve-chamber, and thence to the auxiliary-reservoir, is to be regarded as always open inward towards the valve-chamber, but checked by the check-valve 26 against backward flow into the train-pipe. The Boyden piston, with its check-valve, is borrowed bodily from the old Boyden patent of June 26, 1883, No. 280,285, where it will be found illustrated in Fig. 3 of the patent drawings. (R., pp. 448 and 776). An inventor naturally prefers his own creations, and Boyden preferred his own old form of piston, with its central check-valved feed-passage, and its tubular inward extension or stem. In Boyden's patent of June 26, 1883, four years before the patent in suit, he applied to this check-valved central

feed-passage the term "an always-open, one-way passage;" and it is a construction which Mr. Westinghouse expressly disclaims in the disclaimer which appears in the specification immediately before the claims of the patent in suit. (R., p. 788.)

Now, if the check-valve of this passage be omitted from the Boyden device here in suit, the passage will be absolutely open between the train-pipe and the triple-valve chamber at all times, and in both directions; *but the device will still perform quick-action on the emergency-stop, just as before*, the office of the check-valve being merely to prevent air from passing backward into the train-pipe, and not to prevent it from passing forward from the train-pipe to the valve-chamber. Without the check-valve 26, the device will not operate to graduate, or for service stops, because the auxiliary-reservoir air will escape backwards into the train-pipe. But in making an emergency-stop, the auxiliary-reservoir air has no time to flow back into the train-pipe before the piston is drawn back through its full traverse; and, as the partition chokes off the flow of auxiliary-reservoir air to the valve-chamber, the reduction of pressure thereby affected in the latter chamber allows the train-pipe air to press forward into said chamber, just the same without as with the presence of the check-valve. We mention this fact to show that it is the partition 9 to which the whole credit of quick-action in the Boyden device is due. True, the partition alone will not produce quick-action; *but when added to an old triple-valve capable of performing its old and usual functions, the partition 9 will superadd the function of retaining the train-pipe air for quick-action.*

COMPLAINANTS CONTEND THAT THE BOYDEN DIFFERENTIAL PRESSURES ARE FOUND IN THEIR STRUCTURE.

This is absolutely untrue; of course all tripe-valves, in operating, must have differential pressure, but none have those differential pressures which are produced in the operation of the Boyden structure. Namely: First, retaining 70 lbs. pressure in

the piston-chamber D; second, *reducing* the prior 70 lbs. in the valve-chamber C to 5 lbs. pressure at the instant that the pressure in the train-pipe is at 55 lbs. and thereby uniting the train-pipe and auxiliary-reservoir pressures in the triple-valve chamber and simultaneously venting them together through the port opened by the old main-valve of the triple-valve. (See card 6, with model of defendant's structure.) *This* kind of differential pressure never existed in any triple-valve prior to Boyden's invention, nor does it exist in the complainants' structure. Nowhere have complainants pointed out in their structure that the maximum pressure of 70 lbs. in the main-valve chamber is *reduced* from 70 lbs. to 5 lbs., and thereby *make the main-valve of the old triple valve vent the train-pipe pressure* at the instant it vents the auxiliary-reservoir pressure. These are the Boyden differential pressures: and they are not found in the operation of the complainants' structure.

COLORING THE SEVERAL VALVES DIFFERENTLY.

When this case was first presented in the Circuit Court the defendants adopted the method of coloring the corresponding valves in the defendants' and complainants' structures the same color, and applying a different color for each kind of valve; they also used this method before the Circuit Court of Appeals, the object being to assist the Court in quickly distinguishing the different valves without great labor on their part of tracing the different and numerous lines that form the boundary line of the valves. The complainants did not adopt this system in the lower Courts, but finding that it clearly enlightened the Courts as to just what the different valves were, they have for the first time adopted it before this Court. Now they have a perfect right to do so, but *they use the colors to complicate* and confuse the two structures by omitting and not coloring the corresponding valves alike. For instance, in the cuts of their device opposite page 22 of their brief, they properly color the valves. That is to say, the *release-valve* (green), the sensitive

graduating-valve (yellow); the main-valve (black) and the auxiliary-valve (red) which vents the train-pipe air, but they failed to color the feeding-in valve, blue (see same colored, opposite page 18 of my original brief).

But when they color the valves in the defendants' device, opposite pages 39, 40 and 78, they do not color the feeding-in valve (blue) nor the sensitive graduating-valve (yellow) Now, why did they not frankly put the proper color on all the valves in both structures? The reason is, that if they colored the sensitive graduating-valve 18 in the defendants' structure, yellow, they would have to color the main-valve, 22, black, and therefore there would be no valve left to be colored red, that would correspond to their new auxiliary-valve 41; a procedure that is specious and misleading, and intended to befog rather than elucidate the subject under controversy.

THE COMPLAINANTS' METHOD OF COLORING PROVED TO BE
ERRONEOUS.

Their erroneous method of coloring the valves is conclusively proved by numerically comparing the valves in both structures.

COMPLAINANTS' STRUCTURE.	DEFENDANTS' STRUCTURE.
First: Feeding-in valve (blue).	First: Feeding-in valve (blue).
Second: Release valve (green).	Second: Release valve (green).
Third: Graduating valve (yellow).	Third: Graduating valve (yellow).
Fourth: Main valve (black).	Fourth: Main valve (black).
Fifth: Auxiliary-valve (red).	(No fifth valve).
Making five in all; four belong to the old triple-valve and one belongs to the <i>new</i> machine.	Making four in all, and all of which belong to the old triple-valve.

Therefore it is obvious that complainants' red color on the main-valve in the defendants' structure, to show that it is an

auxiliary-valve, has no justification, and is absolutely misleading and erroneous.

THE NUMEROUS IMAGINARY VALVES ALLEGED TO SHOW MODIFICATIONS OF COMPLAINANTS' STRUCTURE.

The complainants have inserted cuts of numerous imaginary valves in their brief for the purpose of trying to break the force of defendants' coloring. Now these imaginary valves are not in the record. There is no testimony pertaining to them nor have the defendants had an opportunity to rebut the statements pertaining thereto, and therefore they should be considered with great caution if considered at all by the Court.

It is a conspicuous fact about these numerous valves which purport to show that the complainants' and defendants' structures are substantially the same, that in those shown opposite p. 62, of plaintiffs' main brief, which are minus the Boyden Partition 9 dividing the valve-chamber from the piston-chamber, *two* valves and a by-passage are required to vent the two airs; i. e., a red valve to vent the train-pipe air and a black valve to vent the auxiliary-reservoir air; and those opposite p. 64, that show one valve venting the two airs without any by-passage *have* the Boyden Partition 9. Therefore these very imaginary valves prove that by the use of the Partition 9 *one* valve is made to perform the two functions, and where the partition is not shown, *two* valves are required, and this is just where the difference is between the two inventions. In other words, Westinghouse uses the old main-valve (black), of the triple-valve to vent the auxiliary-reservoir air, and a *new* valve (red), to vent the train-pipe air; whereas Boyden uses only the old main-valve of the triple-valve to vent *both* the auxiliary-reservoir air and train-pipe air. (See card 6, small models of defendants' device.)

Designate, color, or arrange these as you may, when you find one valve venting the two airs, *that* is Boyden's invention, and where you find two valves venting the two airs that

FOLDOUTS TOO LARGE TO
BE FILMED

is Westinghouse's invention. This rule is infallible and distinctly defines the difference between the two inventions, and should they be put into a hundred different imaginary forms the two inventions can be immediately distinguished by the application of this rule.

It is submitted that it is opposed to common sense to multiply indefinitely the structures by inserting cuts of imaginary forms that only tend to confuse instead of shedding light on the subject, and that, too, by imaginary forms that have not been *testified to*.

Patent 360,070 Not a Pioneer or Meritorious Invention.

The complainants in order to get a broad and general construction of the patent in suit, and to impress the Court with its alleged merit and magnitude, have endeavored to establish a "pioneership" for it that is wholly specious and not consistent with the facts of history pertaining thereto.

To construe the claims of the patent in suit as liberally and broadly as the circumstances and language of the claims will permit, is proper, and is but justice to the complainants; but in view of the failure of this device to solve the problem of quick-action air-brake, to give the patent undue credit as a meritorious invention, and then use that credit as a reason for expanding the claims, would be a wrong to both defendants and to the public.

EXHIBIT OF 1879, 1887 AND 1888 PATENTS.

The illustrations on folded insert show just where the patent in suit stands as to pioneership and just how meritorious it is.

PATENT OF 1879—DISCLOSING THE FUNDAMENTAL LAW OF QUICK-ACTION.

The drawing to the left represents the device which disclosed the fundamental law of consecutive quick-action, and that law is applied in every quick-action brake of to-day. It was patented

in 1879, in the United States, by Mr. Westinghouse. It consists, first, of a train-pipe; second, an auxiliary-reservoir; third, a brake-cylinder; fourth, triple-valve, all of which are old and constitute the plain automatic brake, and in order to quicken the serial application of the several brakes in a train, it has combined with it an *auxiliary-valve*, colored red, to vent the train-pipe, and a supplemental-piston, colored brown, to actuate the auxiliary-valve. Now, in its operation when a quick-action is to be made, sufficient air is discharged by the engineer from the train-pipe to move the piston of the triple-valve its full stroke and open the main-valve (black) to fully apply the first brake with auxiliary-reservoir air, the course of the air being shown by a red line, and at the same time this discharge of air by the engineer moves the supplemental piston (brown), which opens the auxiliary-valve (red) at each car and vents the train-pipe air, its course being shown by a blue line, resulting in effecting the quick application of the brake on the following car, and so on throughout the train, producing a nearly simultaneous application of the several brakes. (R., p. 759, L. 42.)

THE UNSUCCESSFUL DEVICE OF THE PATENT IN SUIT OF 1887.

Now, in 1886 or 1887, Mr. Westinghouse took this fundamental law of 1879 and applied it in the device of the patent in suit, shown in the central figure. In the 1879 device the auxiliary-valve device (red) was actuated by a supplemental piston, but in the 1887 device the supplemental piston was dispensed with and the auxiliary-valve located in the triple-valve casing, in such relation to the piston thereof that the latter was endowed with a new *function* simultaneously with the performance of its old function of opening the main-valve (black) to vent the auxiliary-reservoir air, shown by a red line. The new function consists of opening the auxiliary-valve (red) to vent the train-pipe air, shown by a blue line, thereby resulting in quickening the action of the following brakes in the train, the

same as in the prior device of 1879, except that the auxiliary-valve (red) in 1887 is actuated by the triple-valve piston instead of by a *supplemental* piston, as in 1897. Now, this 1887 device on public trial at Burlington, Iowa, in 1887, failed to apply the brakes throughout the train sufficiently quick, and produced worse shocks than before, and therefore was unsuccessful. (R., p. 128, L. 12.)

THE SUCCESSFUL DEVICE OF 1888. (AT RIGHT HAND OF FOLDER.)

Mr. Westinghouse then constructed the successful device of patent January 21, 1888, not in suit, shown to the right, and again reverted back to his 1879 patent, and in addition to adopting the auxiliary-valve (red) thereof, he also at last adopted the *supplemental* piston (brown) thereof, and combined the *two* with the old triple-valve, so that when the brakes were to be quickly applied, the auxiliary-reservoir air, shown by a red line, was admitted to the brake-cylinder by the main-valve (black), and also to the chamber containing the supplemental piston (brown), and that piston opened the "auxiliary-valve," which vented the train-pipe air, shown by a blue line. With this combination, which is not in suit here, he obtained satisfactory results.

Now, from this history, it is quite obvious the patent in suit was *not* the first to disclose the fundamental law of serial quick-action, as that was made known in 1879 by patent No. 217,838 (R., p. 759), nor was it the first to practically apply *that law*, as that was accomplished in 1888 by the device of the patent No. 376,837 (R., p. 131, L. 12). Therefore, the complainants' contention that the patent in suit is a great, meritorious and pioneer patent is erroneous, and not well founded.

FUNDAMENTAL LAW DISCLOSED PRIOR TO THE
WESTINGHOUSE 1879 PATENT.

Furthermore the fundamental law shown in the 1879 patent to Mr. Westinghouse was not first disclosed by him, as it was

first patented in England (R., p. 68, line 7), March 12th, 1879, No. 980, by Sanders. Mr. Westinghouse was in England about that time, as his signature to the specification of the United States patent, No. 217,838, was witnessed at 17 Grace-Church street, London, E. C. (R., p. 761), and his application for the United States patent was filed May 21st, 1879, (R., p. 759, L. 4), two months after the English patent was published to the world.

VENTING THE TRAIN-PIPE AIR TO THE BRAKE-CYLINDER DIS-
CLOSED PRIOR TO THE WESTINGHOUSE PATENT OF 1887.

Nor was Mr. Westinghouse the first, in the patent in suit, to vent the train-pipe air into the brake-cylinder, to augment the pressure therein, as that was done by Mr. Boyden and patented to him June 26, 1883, and that patent was the cause of the rejection and erasure of Mr. Westinghouse's broad claim from the patent in suit. (R., p. 717, L. 18).

WHY THE DEVICE OF PATENT IN SUIT WAS UNSUCCESSFUL.

Now, let us see why the device failed. It will be observed that the first device of 1879, and the last, the successful device of 1888, both use auxiliary-valves, but actuate them by *supplemental* pistons; whereas the intermediate device of patent in suit does not use any supplemental piston, but uses the *old further traverse* of the piston to actuate the auxiliary-valve, thereby requiring the said piston to perform a new and *additional function*, or perform the double duty of opening the main valve (black) of the triple-valve to vent the auxiliary-reservoir air, and also opening the *auxiliary-valve* (red) to vent the train-pipe air. This double work necessarily makes the piston move slowly and requires a greater reduction of train-pipe air to actuate it, which results in a piston action *too slow* to sufficiently quicken the application of the brakes throughout the train, therefore *this double work of the piston* is what caused the failure of the device of the patent in suit. This defect was

remedied in the 1888 patent by utilizing the supplemental piston, and thus relieving the triple-valve piston of the extra work.

A SIGNIFICANT FACT.

It is a significant fact that when "auxiliary-valves" are used *successfully* a supplemental piston is used to actuate them, and this fact proves that the defendants' device does not use an auxiliary-valve, and that the main-valve 22 is *not* an auxiliary-valve, because, if it were, the piston would have to perform an *additional function*, and to do double work, and thereby the defendants' device, which has proven successful, would be impracticable, for the reason that the device of patent in suit was unsuccessful.

COMPLAINANTS' EXCUSE AS TO FAILURE OF THE
PATENT DEVICE IN SUIT.

The complainants explain that the failure of the patent in suit was due to no inherent defect, but to the small size of the ports of the valves, and that when the ports were made larger the device worked substantially as well as the 1888 patent, where a supplemental piston is used. Now, there is no testimony which sets forth where and when this was tried or proven to be true, and the fact remains that if it is true, why do the complainants complicate their successful device with a supplemental piston when so simple a thing as *making a port larger* would remedy the defect? The physical facts are, that if they made the port under the auxiliary-valve larger the air-pressure on that valve would be increased, and consequently the resistance to its movement would be increased in the same ratio, thereby resulting in making the piston of the triple-valve move still more slowly, requiring a greater reduction of train-pipe pressure and the brakes would be more retarded than if the ports were the size shown in the patent. The records shows that they experimented with the device of patent in suit several months after its failure at the Burlington trials (R., p. 148, X-Q. 159) and at

last accomplished the desired result only when they reverted back to the supplemental piston of 1879 patent. Their allegations are wholly inconsistent with the facts disclosed by the records and with physical reasons herein given.

COMPLAINANTS' CONTENTION AS TO THE QUICK-ACTION
DEVICE OF 1879 BEING INOPERATIVE.

The records show that the defendants made fifty of the devices of the patent No. 217,838 of 1879 and tested them on a rack equipped with fifty brakes, just as in practice, and the devices *did work as set forth in the patent* (R., p. 669, L. 37), and did greatly quicken the action of the brakes and that they were operative. Now, on the other hand, what does the record show about the operation of the device of patent in suit? It proves that it was a failure (R., p. 126, L. 26), and it required great inventive skill and several months' work to accomplish the result, and then it was not by the device of patent in suit, but by another device for which they procured the 1888 patent. It is therefore submitted that if, according to complainants' contention, the first device (1879) was inoperative, and therefore should not be favorably considered, why should the second device (1887) receive favorable consideration since it was proven to be a failure, and is not now used, and never shown in their catalogues (R., p. 149, L. 31). The device of 1879, at least, has the credit of being the first in the United States to show the fundamental law of quick-action, and to show a *supplemental piston* actuating an auxiliary-valve, which are embodied in the successful device of 1888; but the *actuating* of the "auxiliary-valve" by the triple-valve piston, *the leading thing of the patent in suit*, and which the complainants set such stress on here, is not used at all by them or any one else, nor has it ever been used since its failure at Burlington in the spring of 1887.

In calling the attention of the Court to the patent of 1879, which discloses the fundamental law of serial quick-action, and

to the fact that the patent in suit was inoperative to produce the result sought for, and to the other matter just referred to; it is not for the purpose of belittling the patent in suit, but this is done for the purpose of rebutting the great pretensions of counsel as to the *merits* and *pioneership* of that patent, and their efforts to have it construed for something more than the facts surrounding it warrant.

SUMMARY.

First: That the complainants' invention consists of the old automatic brake plus a second machine consisting of: (A) an additional passage; (B) an auxiliary-valve controlling the said passage; and (C) endowing the triple-valve piston with a *new or additional function*: i. e., to actuate the said auxiliary-valve.

That the defendants' device does not contain an additional passage or an auxiliary-valve or use the piston to perform a *new or additional function*: and, therefore, is for a wholly different invention, and does not come within any claim of the patent in suit.

Second: That the complainants' contention and assertions as to the patent in suit being meritorious and pioneer, are fallacious and not supported by acts, for instead of possessing these qualities, that device is simply an unsuccessful patent which does not possess even the merit of being the first to disclose the fundamental law of quick-action, nor of being the first to reduce that law to practice and, therefore, should not be construed by this Court to be for anything more than just what it fairly describes.

Third: That the defendants' invention is meritorious as being the first to disclose that the triple-valve *per se* possessed in itself latent powers to vent the train-pipe air without complicating the automatic-brake system with additional or auxiliary-valve devices of any kind; and further, that this great change was brought about by the most simple means imaginable (Partition 9). A device that cannot get out of order, that needs

no repairing, and which is absolutely sure to act when called on in emergency to prevent loss of life and the destruction of property.

Fourth: To hold the defendants' device an infringement of the *unsuccessful* and the *unused* (R., p. 149, L. 36), device of the patent in suit would tend to discourage rather than encourage progress in mechanical art, and, furthermore, not only prevent the railroad companies from using a device that had advanced the art one step forward, but would maintain a monopoly that last year netted over two million, six hundred thousand dollars profit, and cut the railroad road companies off from the benefit of competition in supplying themselves with air-brakes, which, by law, they are required to use, and that, too, by a patent for a device which the railroad companies decided *not* to use after being tested by the most proficient experts in the country, the Master Car Builders' Committee, who reported, in 1887, after the test at Burlington of the device of the patent in suit, that "the field for improvement was open as wide as in 1886." (R., p. 126, L. 26).

Fifth: We consider that it is proper and just to construe the claims of the complainants' patent so as to cover the invention described therein; but should not be expanded so as to cover the defendants' device, which does not use the invention described in the complainants' patent as a whole or in one detail, and which operates by an entirely different mode of operation.

Respectfully submitted,

LYSANDER HILL,
Of Counsel for Defendants.

APPENDIX

IN ANSWER TO

PLAINTIFFS' SUPPLEMENTAL BRIEF.

Further Traverse of the Piston.

The great theme of complainants' counsel is, the utilization of the "further traverse" of the triple valve piston to do work that it never did before, by which great and beneficial results are accomplished. For the first time in this litigation they now concede before this Court that the *further traverse* is old, but they say it possessed defects, and Mr. Westinghouse's "remarkable invention in suit converted the cause of difficulty into an element of success." On page 3 of supplemental brief they solicit the admiration of the Court, when dilating on the further traverse, by stating that—

"Such triumphs in mechanics are only achieved by those whose genius is of the supreme quality which enables a commander to snatch victory from defeat."

And Mr. Betts, in the most impressive manner, told this Court in substance at the prior argument, that—

‘When in case of an emergency, as when a draw-bridge was open or a switch misplaced, or some deadly danger ahead, that then the engineer, by the means at his control, could utilize the further traverse of the piston *‘to perform a new function’*—to do work it never did before, and thereby vent the train-pipe air, which instantly causes the brakes to be applied throughout the train with lightning-like rapidity, and with the greatest available force, resulting in saving the lives and limbs of numerous passengers, and the property of the railroad company; and that the utilization of the *‘further traverse of the piston to do work that it never did before* is the great and underlying principle of Mr. Westinghouse’s invention, and one that well deserves a broad and liberal construction by the Courts; and as claim 2 more *nearly* covers that invention, it should not be limited ‘by a *slavish* adoption of the *identical* instrumentalities shown.’

Now, the alleged facts set forth in this argument can safely be conceded by defendants, for the very reason that this great and underlying principle contended for—to wit, the further traverse of the piston “*performing a new function*” and doing work that it did not do before, by which train-pipe air is vented, **is not used by defendants**. And further, this very point forms the parting of the ways between the complainants’ and defendants’ respective inventions.

Mr. Westinghouse took the old triple-valve (patent 220,556) and when the piston made its old “further traverse” to open the main-valve (black) to admit auxiliary-reservoir air to the brake-cylinder for emergency applications of the brakes, as it always did, he utilized that old further traverse of the piston and caused it to do *additional work*, that of opening an auxiliary-valve which did not previously exist in triple-valves, to

vented the train-pipe air, thereby Mr. Westinghouse endowed the *further traverse* of the piston with "*a new function*."

Now Mr. Boyden in order to reach the result of venting train-pipe air, proceeded on a very different principle from that of utilizing the "*further traverse*" of the piston to do additional work or to "*perform a new function*." He took the old triple-valve and when the piston made its old further traverse to open the main-valve (black) to admit auxiliary-reservoir air to the brake cylinder for emergency applications of the brakes, just as it always has done, he modified the old triple-valve chambers by *inserting a partition*, whereby the maximum air-pressure of 70 lbs was reduced to 5 lbs. in the main-valve chamber, and thereby the train-pipe air is vented through the main-valve simultaneously with the venting of auxiliary-reservoir air, thus not requiring the "*further traverse of the piston*" to do any thing more or less than it always had done. Consequently, conceding as true what counsel for complainants say, as to claim 2 being broadly for the further traverse of the the piston "*performing a new function*" of opening a port, or doing anything else imaginable, more than it did before, by which train-pipe air is vented, the defendant's device, not operating so that the further traverse of the piston "*performs a new function*," cannot be held an infringement of that claim.

Misleading Cuts.

Another procedure of complainants' counsel which calls for serious comment, is the introduction of cuts representing imaginary devices not in the record. These cuts and accompanying statements are essentially misleading. This was resorted to, to a very large extent, in their main brief, but in their supplemental brief they introduce *incomplete* cuts which they pretend represent the different positions and actions of the defendants' valves, but which are wholly erroneous.

Plaintiff's Counsel's Imaginary Valve Positions.

Opposite page 8 plaintiffs' supplemental brief, they show the upper cut opposite, as representing the valves of Boyden structure in the "graduated" position.

It will be noticed that the graduation valve-port (40) is only slightly open with reference to the main-valve, 22, so that air, shown by a red line, can barely enter. This position is absolutely erroneous as the Boyden "graduating valve" never takes any such position. In graduating the small port (40) is open full, as shown by the lower cut opposite, which is the same as shown opposite page 10 of complainants' supplemental brief, which they allege is the position for a "full" application of the brakes.

The alleged position in the upper cut is *never* taken, and the position shown in the lower cut is the one *always* taken *for graduation*, and the reason that the small port will never partly open as alleged is, that when the piston once starts to move towards the train-pipe it will not stop until the shoulder of the stem comes in contact with the main-valve, 22, as shown in the lower cut, consequently the port in the graduating valve is always open to its full capacity when graduating.

By this newly-created position (existing nowhere except in the minds of plaintiffs' counsel), of defendants' graduating valve partly opening the port 40 to graduate the brakes shown in the upper cut, the piston would necessarily make its "preliminary traverse;" then to open the graduating port wide for a "full" application of the brakes, shown in the lower cut, the piston would have to make the "further traverse." Now as there are only *two* "traverses" to the piston, we ask how is the main-valve 22 to be opened? The ingenious counsel for Complainants should have invented a *third* traverse to open valve 22, in order to get their erroneous allegations out of this predicament. They have not seemed to realize this, or possibly they did, and this last view might account for the abridgment of the

Cut from Plaintiff's Supplemental Brief.

(Opposite Page 8)

Alleged to represent the graduated position of defendant's Graduating Valve but which position in fact never exists, as port 40 is never partially opened as it always remains full as shown in the lower cut.

Cut from Plaintiff's Supplemental Brief.

(Opposite Page 10)

Alleged to represent the full application position but which in fact truly represents the graduated position.

E.—The only difference between the two cuts is that port 40 is partially open in the upper cut and fully open in the lower cut.

The Valve 22 is *erroneously* colored Red, in order to have the coloring correspond with Plaintiff's cuts, and for the same reason the Graduating Valve is colored Black.

cuts, because if the relative parts had been shown complete, this *discrepancy in the traverses of the piston* would be at once apparent. The court will see the illogical and ridiculous outcome of an argument based on the invention by counsel of imaginary positions shown by cuts not in the record, and which have not been subjected to rebuttal evidence.

Now the plaintiffs' counsel resort in this specious graphic argument about "graduated" and "full" application with the small port 40 in order to reserve the old main-valve 22 of defendants' structure to be classed as the new auxiliary valve of patent in suit.

In this proceeding counsel fails to point out in defendants' structure the valve equivalent to the graduating valve (yellow) of the old patent 220,556 and also in patent in suit, and make the defendants' graduating valve 40 (which they erroneously call the "main-valve") take the place of *both* the graduating-valve (yellow) 29 and the main-valve (black) 14, of patent in suit. This is a startling proposition and is the handiwork of counsel, as the abridged cuts and the imaginary positions are not part of the record.

Plaintiffs' Counsel's Imaginary Air Action.

The phenomenal air action shown in cut opposite following page, reproduced from plaintiff's supplemental brief, page 11, which their counsel allege "*shows an additional operation*" of the train-pipe and reservoir airs (blue and red lines, respectively), in defendants' device, is wholly misleading. This graphically-displayed piece of fiction is even more startling than their previous one on account of the physical impossibility of accomplishing it, although plaintiff's counsel have the boldness to allege that it shows the action of the two airs (blue and red) in defendants' device.

The action that *actually* takes places by the train-pipe air (blue) and auxiliary-reservoir air (red) in defendants' device in a quick-action application of the brakes, is shown in the lower

cut opposite page 69 of this brief, where the two airs enter the triple-valve chamber and there commingle, becoming one air, and as impossible to *separate thereafter* as it would be to separate hot and cold water after they had been united. How, then, is it possible for the *two* airs to separate in the valve-chamber, as illustrated in the cut opposite, and portions of the auxiliary-reservoir air (shown by a red line) seek out the small graduating passage in the valve-stem and pass through it, while the train-pipe air (shown by a blue line) passes through the large port opened by the main valve 22?

To suggest such an absurd, preposterous physical action as this can only be the resort of persons in dire extremity.

This illustration is wholly misleading, and is used in order to *try* to show that in defendants' device, when a quick application takes place, two valves are employed (which is not true), one to vent the auxiliary-reservoir air (red line) and the other train-pipe air (blue line) with the object of making it appear like complainants' device where two valves *are used* in a quick application, viz: the main valve 14 of the triple-valve to vent auxiliary-reservoir air, and the "auxiliary-valve" 41, separate and "*independent*" from the main valve, to vent train-pipe air. The illustration is spurious and purely imaginary. No such operation of *two* valves is found in defendants' device, for the fact is the main-valve 22 (*one valve alone*) admits both airs, or rather the two airs, after they have been united in the valve-chamber which precludes any such ridiculous alleged operation of the two airs as suggested in plaintiffs' illustration.

Plaintiffs' Counsel's Imaginary Partition.

Plaintiffs' counsel, realizing the importance of defendants' position in regard to Mr. Boyden's invention of *partitioning* the valve-chamber, by which the old triple-valve is made capable of venting the two airs in quick applications of the brake, have endeavored, by the illustrations opposite page 12 of their supplemental brief (illustrations that are not in evidence), to show

Cut from Plaintiff's Supplemental Brief.

(Opposite Page 11)

Alleged to represent a new operation in the Boyden structure, but which is wholly impossible because the Train Pipe Air (blue line) and Reservoir Air (red line) unite in the Valve Chamber and can never separate thereafter and consequently could not take the diverging and separate courses shown.

NOTE.—The Valve 22 is *erroneously* colored Red, in order to have the coloring correspond with Plaintiff's cut, and for the same reason the Graduating Valve is colored Black.

that plaintiffs' device contains a partition equivalent to Boyden's in order to make it appear that if *such* partition was removed quick action in the plaintiffs' *device* would be destroyed.

This *alleged* "equivalent partition" is marked X in the lower cut of said illustrations. Now, a partition, of course, does exist in plaintiffs' device, as partitions of *some* character must necessarily exist in *all* triple-valve devices, which, if broken or removed, would obviously destroy the quick-action application. But what conceivable bearing can *such* a partition have in the case at bar? The fact that the removal of a portion of the *wall* would destroy quick action, does not prove that *it* is the "equivalent" of Boyden's partition.

The removal of the passage 46 would also destroy quick-action and counsel might, therefore, call *it* the "equivalent" of Boyden's partition, but it would not be true. However, the *wall* marked X does not functionate to make the *old triple-valve* capable of venting train-pipe air in plaintiffs' device, as the defendant's partition 9 does in their device, and therefore the part X is *not* the "equivalent" of the defendants' partition 9. If such were the case, and *that* is Mr. Westinghouse's invention, we ask why did he *add* to the old triple-valve the "auxiliary-valve" 41 and the direct passage 46, which in the patent are designated as "additional members?" And why did he fail to describe such a partition in his patent, if thereby he could dispense with his *additional* members? This cut opposite page 12 of plaintiffs' supplemental brief is another piece of fiction, and the contention of plaintiffs' counsel is treating a very serious subject as though it were a farce, is wholly unwarranted from anything found in the Record, and is totally lacking in the dignity and frankness due to a cause before this Court.

Non-Identity.

The learned and ingenious counsel for plaintiffs, realizing that before claim 2, or any other claim of the patent in suit, can be adjudged to be infringed, *identity* must first be established between the two structures, and knowing truly that to produce

quick-action, plaintiffs' device requires the use of two valves at the final traverse of the piston, viz: the main-valve (black) of the triple-valve to vent auxiliary-reservoir air, and an "*auxiliary-valve*" (red) *added to the triple-valve to vent train-pipe air*; and knowing also that in defendants' device only *one* valve, in fact, is used to vent both the airs, *they must*, in order to establish identity show that defendants' device also employs an "auxiliary valve." Being unsuccessful in this matter in the lower courts, plaintiffs' counsel now proceed to introduce some newly-discovered evidence—some inventions of their own—and produce the erroneous illustrated propositions, the rationale of which would, if advanced before expert engineers, be received with ridicule.

The identity or non-identity being the controlling factor as to the determination of the question of infringement, and the plaintiffs depending on establishing identity by proving the main-valve 22 of defendants' device to be the "auxiliary-valve" of plaintiffs' patent, we desire, before closing, to call the Court's attention to the following fact:

The *main-valve* in all triple-valves is the valve which controls the *main-port* from the auxiliary-reservoir to the brake-cylinder, and is always opened by the "further-traverse" of the piston to admit the full and quick flow of air in applying the brakes for an emergency; and the sensitive "graduating-valve" is a valve *supplementary* to the main-valve, and used to admit air partially and slowly in graduating or making "service stops." The nomenclature was given by Mr. Westinghouse himself, and will be found in claim 1 of his patent 220,556, dated Oct. 14th, 1879, (R. p. 766), where the slide-valve is termed the "main-valve," and the sensitive graduating valve as "an auxiliary-valve operated by the same stem *to close or open a port through the main-valve without necessarily moving the main-valve.*" Boyden's stem, i, j, k, (some-

times marked 40), closes or opens "a port through the main-valve without necessarily moving the main-valve," and therefore corresponds *exactly* to the sensitive graduating valve *e*¹ of Westinghouse's patent 220,556 (marked 29 in the patent in suit), and does not correspond in any respect to the main-valve of either patents. Judge MORRIS and the Circuit Court of Appeals were clearly right, therefore, in holding Boyden's stem-valve, i, j, k, to be the graduating valve, and his poppet-valve 22, the main-valve, of his device; and this fact and the finding by the Court that it is a fact is, we submit, decisive of the whole controversy.

Complainants Have Shifted their Position on the Main Issue.

We desire to call the attention of the Court to the very remarkable and, we submit, very unjust position now assumed before this Court by plaintiffs' counsel.

The patent in suit defines the invention as consisting of the old triple-valve, *provided* with *certain* "additional members" to perform the new function (R., p. 786, L. 5), and describes the "additional members" as an "auxiliary valve 41" and a passage 46 leading from the train-pipe to the brake-cylinder (R., p. 786, L. 8).

The plaintiffs' expert (Newbury), explaining his understanding of the combination of devices in claims 1, 2 and 4, alleged to be infringed, and particularly claim 2, which is considered by plaintiffs to "more nearly cover the invention," states (R., p. 28, L. 17):

"This claim 2, when read in the light of the specification, is for a combination of four essential elements or

"devices combined together to form a brake mechanism," as follows:

- a. A main-air or train-pipe.
- b. A reservoir to be attached to a car.
- c. A brake-cylinder provided with a piston which connects with the brake-shoes of the wheels of the car.
- d. A triple-valve provided with a piston and "*a valve mechanism*," the piston having two traverses * * * the preliminary traverse operating the (triple) valve mechanism for the admission of air from the auxiliary-reservoir to the brake-cylinder, * * * and the further traverse operating the "*valve mechanism*" * * * for the direct admission of air from the train-pipe to the cylinder.

It will be observed in the above that the *auxiliary-valve element* of the combination is termed by the expert "a valve mechanism."

The same expert witness finds that claims 1 and 4 describes substantially the same as above, but instead of designating the new element "a valve mechanism" he says in these claims it is an "auxiliary-valve." This witness then alleges that he finds these combinations in the defendants' device by selecting the valve 22 thereof as the "auxiliary-valve," or "a valve mechanism," as he terms it in claim 2.

Thus the plaintiffs rested their *prima facie* case.

The defendants accordingly answered this position of plaintiffs by showing that their structure does not employ "a valve mechanism" or an "auxiliary-valve" in combination with the triple-valve, and that the valve 22 is not an added or auxiliary-valve, but is the *old original main valve* of the triple-valve, endowed with a greater capability, by which train-pipe air may be vented at the same time it (the main valve) opens to vent auxiliary-reservoir air, thereby simultaneously venting both airs through the main valve, without using an auxiliary-valve and

separate passage, the "additional members" of the patent in suit, or their mechanical equivalent in any form.

The case was thus made up, and the position taken by the plaintiffs was defended on *these lines*, and in due course came before the Court for argument.

The plaintiffs in their briefs, pp. 40-41, used in the two courts below, when summing up the position they had taken as to claims 1, 2 and 4, stated:

"Thus it will be seen that this *quick-action* attachment, consisting of an air conduit or passageway directly from the *train-pipe connection* to the brake-cylinder, and a valve to control it, such valve being itself under control of the triple-piston and so combined with the old automatic brake appliances * * * that *this*, the chief novelty and element of utility of the Westinghouse invention now in controversy, is so made the *subject-matter of EVERY claim in controversy* as to give character and effect thereto, and render the scope of the claims co-extensive with the invention."

On *the issue* thus made up and tried in the Circuit Court, Judge Morris said:

"I have not been able to satisfy myself that Boyden 'makes use of an 'auxiliary-valve' in the sense in which that term is employed in the specification and in some of the claims of the patent No. 360,070 now in suit.' (Rec., p. 841). 'And what Westinghouse meant by the 'auxiliary-valve' * * * is such a valve as he described in his specification, and which is independent of and performs none of the functions of the main-valve of the ordinary triple-valves.' Also 'the defendants' valve 22 must be considered to be the main-valve.' (R., p. 845, l. 2.)

The Circuit Court of Appeals for the Fourth Circuit affirmed Judge Morris, and said: (R., p. 881)

"Boyden's (22) is not an 'auxiliary-valve': it is mechanically the original main-valve of the original triple-valve, and it performs the service which is performed

“by the main-valve of 220,556. It is not the mechanical equivalent of valve four (auxiliary-valve) in the attached apparatus of Westinghouse, simply by reason of its taking part in an emergency service in admitting train-pipe air into the brake-cylinder. In the original triple-valve it (the main-valve) performed no other service than admitting auxiliary-reservoir air into the brake-cylinder; *in Boyden's device it continues to perform that service*, and is made incidentally instrumental in allowing the passage of train-pipe air. The performance incidentally of quick-action service does not make it ‘an auxiliary-valve.’ It is the same valve. The incidental *service* is auxiliary, but the valve itself is the same and unchanged. We think the Circuit Court was correct in its view that the poppet-valve 22 of Boyden is the original main-valve of 220,556.”

Now after judgement in favor of defendants; after these findings of fact; after failing to convince the two Courts below that defendants use “an auxiliary-valve” or “a valve-mechanism” combined with the old triple-valve, complainants come into this Court and shift their position, and take a *new* one, one wholly inconsistent with their *prima facie* case against which the defendants’ defended, which new position is as follows:

The counsel for plaintiffs now define in their brief before this Court, p. 80, the plaintiffs’ invention and patent by saying it consists of—

“Certain features of the structure, which confer upon it its new capacity, viz: (1) the *double* traverse of the piston, (2) a passage or way of access, directly from train-pipe to brake-cylinder, and (3) a valve which *controls* that passage.”

“These features are the essential features of the ‘means’ by which the triple-valve piston, in its ‘further traverse,’ acts to perform its function of admitting air directly from the train-pipe to the brake-cylinder.”

On this important point (essentials) the patent specification is clear and explicit and shows that what complainants' counsel call the "*essential features*" to wit, the passage for train-pipe air, and a valve which controls that passage, are expressly stated to be "*additional members*" to the triple-valve, consisting of an auxiliary-valve 41 and passage 46. (Rec., p. 786, L. 5.)

Again in Westinghouse supplemental brief, more recently filed, on page 27, counsel take the new ground that claim 2 should be read by twice inserting the words "*by opening a port.*" By this they mean the Court to understand that claim 2 has no limitation whatever beyond that expressed literally by its words, except what they indicate by the proposed insertion of the words "*by opening a port,*" in other words, the new position taken by counsel in this court is, that they now regard claim 2 to be broader than they thought it to be at the outset of this litigation. Then, they said of the "auxiliary-valve device:"

"That *this*, the chief novelty and element of utility of
 "the Westinghouse invention now in controversy, is so
 "made the subject-matter of *every claim in controversy*
 "as to give character and effect thereto."

But such is not their view now, they have seen reason in the adverse decisions of the two lower courts to shift their position, and they do not hesitate to do it.

We submit that the position now assumed by plaintiffs' counsel is specious and untenable and should be scanned with caution by the Court. Complainants having been defeated in the lower courts on the position first taken are now resorting to one of the tricks of the sophist, to wit., first, manufacture or assume a *new definition* of terms better suited to their purpose, and second, endeavor to have the facts marshalled and judged according to their new and spurious definitions.

Supreme Court of the United States.

Westinghouse vs. Boyden==Air-Brake Case

BRIEF FOR DEFENDANTS ON THIRD ARGUMENT.

INTRODUCTORY.

The issue in this case is infringement of patent No. 360,070, granted to George Westinghouse, Jr. The dispute is almost entirely with respect to the lawful scope of this patent, and particularly of claim 2 thereof. Although there are minor disputes, as for example with respect to the philosophy or theory of operation of Defendants' brake, the decision of these would not effect the main dispute, to which we shall here chiefly direct our attention.

We propose, however, to include in this brief an explanation of, or reference to, all matters which are necessary to an understanding of the case. Our reasons for so doing are, first, that one member of the Court was not present at the previous arguments, and second, that we desire to save the Court the labor of examining numerous briefs in order to ascertain our position on the material points in controversy. This is our apology for repeating here explanations of many points that are already well understood by a majority of the Court.

The demand of the Court for a third argument of the case indicates that the main issue has proved difficult and perplexing to the Court, and admonishes counsel to scrutinize and be sure of their premises and of the deductions made therefrom.

The attention of counsel has been specially directed by the Court to the question whether the patent sued on "could be sustained as to process or method;" and the specified elements by which this inquiry

is to be determined are "the state of the art, including the patents of Westinghouse," "the proceedings in the Patent Office," and "the terms of the patent itself."

Although claim 2 of the patent sued on is a claim in terms for a combination of elements constituting an automatic air-brake, and not a claim for a process or method, and although no claim is made in the patent for a process or method, nor is any process or method described in the specification, one contention of Complainants is that this claim should be so construed as to cover the operation of admitting air directly from the train-pipe to the brake-cylinder, whenever that is done *for the purpose* of securing a "quick action" of the brakes.* A claim for a new "process or method" is therefore advanced in the argument, though not made in the patent; or, in other words, Complainants contend for such a construction of claim 2 as, if it be adopted by the Court, would be tantamount to sustaining the claim as to the process or method.

Analysis of this contention discloses that it is based primarily upon the proposition that the invention of the patent sued on is of "primary" character, and that the patent is a "pioneer" patent. The position taken by Complainants' counsel appears to betray recognition of the fact that, if the patent be construed, according to the *ordinary* rule, applicable to *ordinary* patents, (as covering the novel means it discloses and the substantial equivalents thereof) Defendants cannot be held as infringers, and that, therefore, it will be necessary to obtain the aid, in construing the patent, of an *extraordinary* rule, applicable only to *extraordinary* patents, to wit, to so-called "pioneer" patents.

In examining this contention, therefore, we are called upon to answer the following questions:

1. What is a pioneer patent?
2. Is the patent sued on a pioneer patent?

The question of infringement, and the specific question proposed by the Court, may be answered without determining the question of "pioneership;" but this latter question is made a prominent issue by Complainant, and since presumably the Court will pass upon it, it comes within the scope of our discussion.

*It is not contended by Complainants that the patent in suit is the first to disclose this operation, which is admittedly old, but the first to propose it *for a particular purpose*.

The determination of the question of pioneership will depend upon certain material matters of fact. These important or determinative facts are few in number, but it is of the utmost necessity to ascertain these with accuracy, and to apprehend fully their import, for otherwise no step in the deduction which we are called upon to make can be taken with confidence and certainty.

Careful analysis is here required to determine, not only what matters of fact are legitimate premises for the deduction to be made, *but also to distinguish these from facts which are not material to the main issue and cannot be legitimately used as premises in the discussion.* These immaterial facts and illegitimate premises should be rigorously excluded from consideration, and this should be the law of the discussion *for both sides.* We insist, at the outset, upon the importance of this analysis, and of discrimination between material and immaterial matters, because we believe that the main contention of Complainants with respect to the construction and scope of the patent in suit is based upon an illegitimate premise, to wit, upon the achievements claimed for Mr. George Westinghouse, Jr., in the development of the air-brake as the result of inventions made and patented *before* and *after* the particular invention of the patent in suit. What the Court demands to know in this connection is the exact dimensions of the new, practical result attained by the novel means disclosed by the patent in suit. The results of other inventions, whether earlier or later, are material solely for the purpose of *excluding them* from the scope of the patent in suit, and thus arriving with greater certainty at the exact extent of the result accomplished by and due to the specific invention of that patent.

We shall further require in our discussion precise definitions of certain terms of frequent occurrence in this case, so that *whenever such expression is used* it may convey *the same meaning*, and always *that specialized meaning given to it* in this case.

With a firm grasp on these essential things we may enter upon the discussion of the issue with a reasonable expectation of arriving at a sound conclusion with respect thereto.

DEFINITIONS.

The term "Quick-Action Brake" is used in this case with a specialized meaning. What is that meaning?

There is no natural line of demarkation by which brakes can be classified as either "quick-action" or "non-quick-action." In the development of the air-brake during the past thirty years one aim of inventors has been to quicken the action of the brakes as far as practicable. Every time an improvement in this respect has been effected the result has been a brake which had "quick-action" with reference to what preceded it.

Furthermore, the term "quick-action" may have reference to the operation of each *individual* brake, referring to the interval of time between the act which initiates the operation of the individual brake and the full application thereof. Or it may have reference to the operation of a *connected series* of brakes on the several cars of a train, referring to the interval between the act which initiates the operation of the series of brakes and the full application of the *last* of the series. The distinction here to be observed is that between quick action in the *individual* application of the brake on the one hand, and quick action in the *serial* application of the brakes on the other hand.

Prior to the invention of the patent in suit a maximum in quick-action for individual application of air-brakes had been attained. Abrupt application of the brakes with full pressure is not desired in ordinary or "service" stops, and even for "emergency" stops an application of the brakes as abrupt as is desired or needed was obtained from the auxiliary reservoir, the quickness of action being a mere matter of the maximum size of the valve-opening between that reservoir and the brake-cylinder. In modern practice, the brakes are never abruptly applied, in making emergency stops, with the full power available in the auxiliary reservoir, and which was available in the brakes of the prior art. On the contrary, provision is made to *prevent* the abrupt application of this power to the brakes.

But beyond this the brake-mechanism of the prior art was capable of "quick-action" in the *serial* application of the brakes to the full extent necessary for all trains which were equipped with continuous air-brakes up to that time, or for which such equipment was desired by the railroad interests. Until a short time before the patent

sued on no demand had been made by those interests for air-brake equipment, except for passenger trains, which rarely comprise more than ten cars, and usually a much smaller number. For such trains the old brake-mechanism possessed fully the essential of quick-action in serial application, that essential being that *all* the brakes of the train should be "applied or brought into action simultaneously,"* or practically so.

In 1886 the Master Car Builders' Association made a demand upon the manufacturers of brakes for an air-brake which could be successfully used on freight trains comprising as many as fifty cars, and which when used on trains of that length would be effective for making both "service" stops and "emergency" stops, just as was accomplished by existing brake-mechanisms on short trains. That association determined and stated the requirements which such a brake mechanism should fulfil, among these being that "it shall work without shock on a train of fifty cars" (Rec. p. 133). This requires "practically simultaneous" action of the brakes, or to substitute a definite formula for the indefinite statement "practically simultaneous" it requires full application of the last brake on a train of fifty cars within three and one-half seconds from the operation of the engineer's controlling-cock.† No brake which does not accomplish that is a "quick-action brake," as that term is employed in the art and in this case.

Therefore, when we say that the devices of Complainants and of Defendants are "quick-action brakes," we mean that they are brakes which, when employed on a train of fifty cars, will so operate as that the last brake will be fully applied within three and one-half seconds from the opening of the engineer's controlling-valve. The term, as

* Westinghouse patent, No. 217,838, July 22, 1879, p. 760.

† This formula is given in the proceedings of the Master Car Builders' Association of 1895, (p. 245) in the following words: "No. 2. Application Test (b) (Emergency).—Brakes must be applied on the fiftieth car with at least 45 pounds pressure, with 6 inches piston travel, in three seconds from the first movement of the engineer's handle. They should indicate at least 55 pounds in three and one-half (3½) seconds."

Judge Townsend (59 F. R. 585.) defined the "quick-action element" of the modern brakes as being "such an arrangement of the triple-valve on each car as to make the opening of such vents, and the consequent reduction of train pressure *practically simultaneous on each car.*"

applied to the modern brake, has no distinctive reference to the *individual* application of the brakes, but only to the *serial* application thereof, and to the latter only when the series embraces a very large number, as fifty.

Finally, it is to be noted that "quick-action air-brakes," even in the restricted meaning here given to the phrase, had been produced and operated with entire success prior to the invention of the patent in suit. In the successful "quick-action brakes" the opening of the discharge valves for "emergency" stops was effected by the agency of electricity. Hence a further restriction to the meaning of the phrase is necessary, and we must confine it in this discussion to *quick-action* brakes wherein the defined requisite promptness of serial application is effected by the agency of compressed air alone.

When Complainants' counsel say that Westinghouse was the first to invent and produce a "quick-action brake," they mean a brake which fulfills the requirement specified above, when operated by compressed air alone. Any brake which will do that practically is a "quick-action brake" within the meaning that attaches to that term in the art, and in this case. If the brake of the patent in suit accomplished that it is a "quick-action brake;" if not, it is not a "quick-action brake."

Another term for which at least a proximate definition is much needed is "pioneer invention," and, in defining this, we have also to notice the meaning of the phrase "new result" when used in this connection.

The terms "pioneer" and "primary" are used to designate inventions of peculiar importance, and the mark by which an invention of that character is distinguished from other inventions is the accomplishment thereby of an *industrial* or *practical* result, beneficial to mankind, and which had never before been accomplished. Judge Townsend defined a pioneer invention as one which "*for the first time* enabled 'a law of science, or force of nature, to be used so as to accomplish a *practical* and *beneficial* result'" (59 F. R. 592). Every invention, to be patentable, must produce a "new result," that is, it must present some advantage in efficiency or economy over known devices of the same class, or be characterized by some new and meritorious feature of construction or operation. This merely says that an invention, to

be patentable, must be "useful." But the "new result," in order to place the means which attained it in the rank of "pioneer" or "primary" inventions, must be broadly a new *industrial* result. An invention which merely introduced into an old structure a novel feature of operation with an incidental gain in economy or efficiency, without producing a radically new practical result, would not be a "pioneer" invention.*

Bringing together, then, our two definitions to determine what is meant in this case by the expression "the pioneer quick-action air-brake," we find that that expression applies to, and only to, the brake-mechanism, which, *for the first time in the history of the world, accomplished the full serial application of all the brakes on a train of fifty cars within three and one-half seconds by the agency of compressed air alone.*

If the brake mechanism of the patent in suit did this, it is the "pioneer quick-action air-brake," otherwise it is not. We here concede, *argumenti gratia*, that the first employment of a particular agency (air) to perform a particular office (opening the discharge-valves) which had previously been performed by another agency (electricity) to produce an old result ("quick-action" braking), may be properly dignified by the title "pioneer" invention.

It is only by expanding to this extent the term "pioneer" that Complainants can be allowed, without challenge, to say that Westinghouse was the pioneer inventor of the "quick-action air-brake." Allowing this latitude of meaning, the pertinent question is, was this "pioneer quick-action air-brake," or were the means by which "quick-action" was for the first time accomplished, patented *in and by the patent in suit*? Consulting the briefs of Complainants' counsel for their position on this question, we find that, while they assert with great earnestness that Westinghouse *was* the first to produce the new industrial results of "quick-action" (as above defined) by the use of compressed air alone, they base this assertion on the sum of the results of several inventions patented to Westinghouse, some before, and one (a very

* For example, in the leading case, *Morley Mach. Co. v. Lancaster* (129 U. S. 273) the patent was held to be a "pioneer," because the Court found that Morley was "the first inventor of an automatic button sewing machine." In *McCormick Mach. Co. v. Aultman* (C. C. A. 69, F. R. 371) the inventor was held to be a pioneer, because the invention of the "Gorham patent was the first which successfully bound grain with twine in the field."

important one) *after* the patent in suit. When we look in their brief and arguments for the definite description of that new industrial result which *the invention of the patent sued on* accomplished for the first time in the history of the world, and which, therefore, identifies *it* as a "pioneer" invention, we find that they are not able to attribute to it *any* new industrial result. They here substitute for a new *result* what is merely an *operation* (not in itself *new*), and which might not, and, in fact, *did not*, accomplish the specified *result*. They say on this point—

"*This discharge of the TRAIN-PIPE into the brake-cylinder to produce QUICK-ACTION was absolutely new with him.*" (Westinghouse).*

The italics and capitals in the quotation are those of Complainants' counsel (main brief, p. 17).

Manifestly this assertion—the extreme statement which Complainants' counsel feel justified in making in respect of the result attained *by the patent in suit*—is merely a statement of a *particular place of discharge of the train-pipe*, qualified by a reference to the *object* which the inventor *designed* to produce by discharging the train-pipe into that particular place, and which, without that qualification, would not be a true statement. The force of even this qualified statement is much diminished, if not completely neutralized, by having in view the facts for which counsel were endeavoring to make proper allowance in this extremely guarded statement. These facts are briefly—

1. That the discharge of the train-pipe at the *same points*, by the *same means* (reduction of train-pipe pressure opening valves at suitable intervals along the train-pipe) and for the *same purpose* ("to produce quick-action") was old.†

*The contention of Complainants, to which we shall largely devote attention, is that stated in their main brief filed at the first argument, and which is built upon the proposition that Westinghouse was the "pioneer" inventor of the "quick-action" brake. This proposition necessarily assumes that the *patent in suit* is the patent for that pioneer invention. Complainants' counsel do not assert this, but by dextrous use of language seek to establish it by inference without putting it in issue by direct assertion. We do not know what ground Complainants' counsel will take on this third argument, for they have not always been consistent, and have, on at least one previous occasion, retreated from the contention of pioneership and stood on the proposition that Westinghouse, by the patent in suit, accomplished (not "quick-action") but a more powerful *individual* application of the brakes; that he did this by the further traverse of the piston (which had never been used before for that purpose), and that Defendants accomplished the same result by the same means, and hence infringe claim 2. This view of the case will be fully considered herein.

† Westinghouse patent No. 217,838 (p. 759)

2. That the discharge of the train-pipe "into the brake-cylinder" with the results that necessarily attend that operation *per se* (though not to produce "quick-action") was old.*

3. That, while the *object* sought by "this discharge of the train-pipe into the brake-cylinder" might have been "to produce quick-action" it failed of its object, and that the *result* achieved thereby in respect of quickening the action of successive brakes, was precisely that attained when the discharge of the train-pipe was to the atmosphere, as in the prior art.†

In making the foregoing needed definitions we have brought into view some of the material facts and matters by which the issue must be determined, and particularly have we done so in noting the facts which hampered Complainants' counsel in their attempt to describe a "new result" as accomplished by the patent in suit. What is now of immediate importance is to establish firmly that we have stated those facts fairly and accurately. This brings us to a determination of *the departures presented by the patent sued on from structures of the same class existing previously in the art, and of the practical results of those departures.*

This is to be determined by comparing the structure, operation and result of the patent in suit, with the structures, operations and results of the prior art, including the previous inventions of Westinghouse himself.

It is particularly to be noted that these previous inventions of this patentee can be referred to in the present case *solely for the purpose of limiting and defining the scope of the patent sued on.* (James v. Campbell, 104 U. S., 356.) The merit due to them can be considered in this discussion only to *diminish* the merit to be ascribed to the invention of the patent in suit, and cannot by any possibility be considered to *magnify* the importance of that specific invention.

In all the briefs and arguments that have been presented, here and in the Courts below, the great credit said to be due to Mr. Westinghouse for the development of the air-brake has been urged as a fact which ought to influence the judicial mind to place a broad interpretation upon the particular patent sued on. On the other hand, we contend that the merits of this patentee, as an inventor, so far as they

* Boyden patent, 1883, No. 280,285 (p. 776)

† Dep'n H. H. Westinghouse, p. 124, fol. 185.

have the slightest bearing upon any question before this Court, are precisely such as they would be if this were the only improvement he had ever made, and this the only patent that had ever been granted to him. *For the purpose of adjudicating the issues of this cause justice must be blind to every achievement of this patentee, save that only which was accomplished by the invention of this patent. Other inventions of the same patentee, earlier and later, have the same bearing as if they were the inventions of strangers.*

THE NOVELTY IN CONSTRUCTION AND OPERATION OF THE MECHANISM OF THE PATENT IN SUIT.

The patent sued on, No. 360,070, we shall, for the sake of clearness and to avoid the obscurity due to the use of meaningless numbers, designate hereafter as the "auxiliary-valve patent in suit," designating other patents to which frequent reference is made by appropriate titles which suggest the inventions covered by them.

There is no difficulty at all in determining accurately what new thing or things the patentee did in and by the structure of the patent in suit. The difficulty is not met, and the dispute does not arise until the attempt is made to base upon those new features a construction of the patent which will both stand the test of comparison with the prior art, and at the same time clearly embrace Defendants' brake.

What Westinghouse did by this invention was to add to the old triple-valve structures (such as No. 220,556, of 1879, which we will call the "old automatic triple-valve patent") certain "additional members" (as the patent states), these members being a by-passage from the train-pipe to the brake-cylinder, short circuiting—so to speak—the triple-valve chamber, and an auxiliary-valve controlling it and normally cutting off the communication between it and the train-pipe; and he opened this "auxiliary"-valve by means of the usual spring-pressed stem with which the piston made contact, and which it displaced when making its usual "further" or complete traverse for the purpose of an "emergency" stop.

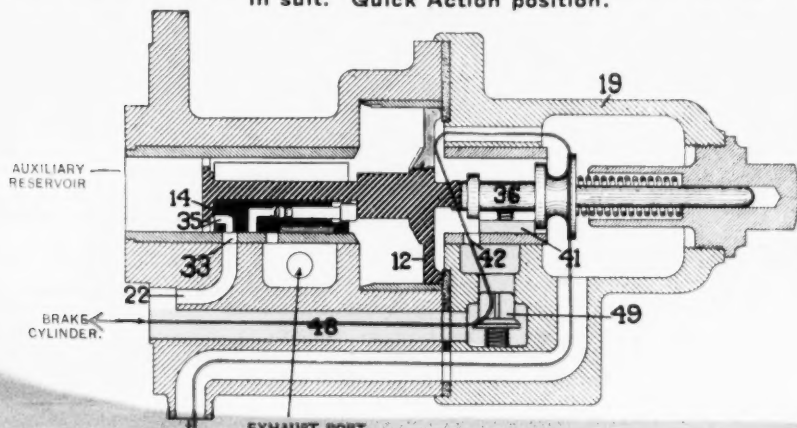

The diagram opposite this page illustrates the structure of the auxiliary-valve patent in suit. Ignoring the parts colored red (which represent the quick-action attachment) we have the old "triple-valve" mechanism of the old automatic triple-valve patent, No. 220,556.

Old Triple Valve device, plus the "Auxiliary Valve device" of the patent in suit. Released position.

Old Triple Valve device, plus the "Auxiliary Valve device" of the patent in suit. Quick Action position.

FOLDOUTS TOO LARGE TO
BE FILMED

BLEED. THROUGH POOR COPY

The triple-valve takes its name from the presence of three valves in a common valve-chamber. These are, *first*, the "feed-in" valve *a*, colored blue, the "release"-valve *s*, colored green, and the "main-valve" *H*, colored black. These valves have a common actuating organ, to wit, the piston *G*, which, in turn, is moved by varying the air pressure in the train-pipe. The main-valve *H* controls the passage *C*, leading from the valve-chamber to the brake-cylinder. As usual in triple-valves of the prior art, the main-valve has a subordinate member, termed the "graduating"-valve (colored yellow in the cuts), whose function is, upon a slight reduction of train-pipe pressure and a correspondingly slight movement of the piston *G*, to uncover a relatively small part of passage *C*, and thus admit air from the auxiliary-reservoir to the brake-cylinder, applying the brakes gradually and with moderate pressure. Thus, while we find in the old automatic brake a *fourth* valve, if we regard this (as it is in fact) as but a subordinate member or part of the main-valve, the term "triple-valve" is not inappropriate.

When, on a greater reduction of pressure in the train-pipe, the piston is moved still further forward, making its "further traverse," it moves the main-valve so as to fully open the port *C*. This port *C* is larger than that controlled by the graduating (yellow) valve, thus admitting air more rapidly and abundantly, and thereby producing a quicker maximum application of the brakes. This further movement of the piston was always resorted to in emergencies, or whenever it was desired to stop the train quickly.

In this "further" or "emergency" traverse of the piston it made contact with the end of stem 36, and displaced the latter against the pressure of its spring. In the old brakes this stem performed no office except to check the piston at the end of its preliminary traverse.

By the patent in suit the parts colored red were added to this old structure. These added parts comprise a passage, 46, from the train pipe side of the piston to the brake-cylinder, and an "auxiliary"-valve, 41, normally closing said passage. This auxiliary-valve was mechanically connected with the stem, 36, so that this plunger performed the new office of actuating this valve, while the piston performed its old office of displacing stem, 36. It may be said that indirectly the piston performs a new office, in that it actuates stem, 36, and through it valve, 41. But in the same sense it may

with equal accuracy be said that, by reason of the addition of valve, 41, the engineer's-valve on the locomotive performs a new office, because it indirectly actuates valve 41.

The operation is such that when the engineer operates his valve, as before, and the pressure is reduced as before, and the piston makes its further traverse as before, and stem, 36, is displaced as before, valve 41 will be opened by said stem, and the air in the train-pipe will discharge into passage, 46, and thus quicken the action of the brake next in series.

Here then is the basis which Complainant's counsel have for stating that, in the brake of the auxiliary-valve patent in suit, the further traverse of the piston produces a new effect, or performs a new *operation*, to wit, discharging the train-pipe into the brake-cylinder.

What were really the *new* means which performed, in this structure, the indicated operation is a controverted matter and one which must be decided before the test for infringement can be applied.

In this structure and its operation we have also the basis (if any there be) for the contention that the patent can be sustained as to method or process; although before that question can be answered the extent of novelty in the structure and its operation must be determined by reference to the prior art.

If it be held that the patent can be sustained for this process or method, the further question remains, does the brake of the Defendants, when used to produce quick-action, employ this process; i. e., does it have a piston, which, by a further traverse, "admits air directly from the train-pipe to the brake-cylinder?"

THE PRACTICAL RESULTS ACCOMPLISHED BY THE INVENTION OF THE PATENT SUED ON.

No exception will be taken, we think, to the accuracy of the foregoing statement of the novel features of construction and operation in the patented brake. We will, therefore, not interrupt the thread of the argument at this point to make minute explanations of the new structure, or minute comparisons thereof with old structures.

We have now to ascertain the *practical result* of this invention with special reference to the advance made thereby in the direction of producing a "quick-action brake." On this point we will depend upon

the deposition of Mr. H. H. Westinghouse, general manager of the Westinghouse Air Brake Company. This matter must be determined for its bearing on the question of "pioneership," but the chief importance of the inquiry, in our minds, is to determine with certainty what is the *cause* of "quick-action," and what are the *agencies* through which that cause operates in Complainants' brake to produce that result. These *agencies*, if new, are the patentable "means."

The brake of the patent in suit was specially designed to remove the difficulty which prevented the old automatic triple-valve of patent No. 220,556, then in general use, from being employed on long trains—that difficulty was the lack of sufficiently close approach to *simultaneous application of all the brakes*. The interval between the application of successive brakes on a train of fifty cars produced violent shocks, due to the fact that the forward cars of the train were checked before the speed of the cars further from the locomotive was diminished. Stated with precision, it was found that on a train of fifty cars, equipped with the standard automatic brakes, it required *twelve seconds* to apply fully the brakes of the last car.

This slowness of serial application was due to the fact that the air discharged from the long train-pipe to operate the brakes had only a single discharge opening, which was located at the engineer's valve, and hence the effect of opening that valve was not felt at the last brake until an appreciable time after the first brake was fully set (p. 123).

These old automatic brakes, under the conditions specified, were fully tested at Burlington in 1886, and in the report of the Master Car Builders of June, 1887 (p. 118), the result was summed up by this statement:

"The result of these 1886 tests was disappointing. None of the competitors, in the estimation of your committee, did satisfactory work, *owing to the violent shocks produced in stopping.*"

In other respects the results appeared to be satisfactory, for while "the expected delays in discharging and releasing continuous brakes were shown to be of no moment, * * * the objection of *successive application* was developed to an extent calling for the most serious consideration."

The violence of the shocks or collisions was registered in these tests by an apparatus called a "slidometer." A movement of 12

inches of the slidometer was found to be injurious to live stock and equipment, while movements of from 12 to 20 inches were destructive (p. 119.) "With the train fitted with the Westinghouse 'automatic' brake the maximum shock was *forty-nine* inches on 'emergency' applications" (p. 120.)

The principal object then to be attained was to prevent those shocks by bringing about quicker "*successive* application" of the brakes, which was shown to be the one thing needful. The cause of this slowness was well known, and Mr. Westinghouse had many years previously perceived that practically simultaneous action of all the brakes could be brought about by providing the train-pipe with a number of doors or exits for the air (one under each car), by opening which the air could discharge, thus quickly relieving the pressure along the entire length of train-pipe. He also perceived that these doors could be made to open *by the reduction of pressure* in the train-pipe itself. All this he had disclosed, and the means for effecting it he had patented in 1879, patent No. 217,838, which we will hereafter call the 1879 "local-vent" patent.

In that patent he had *not* thought of operating these discharge valves through the intermediary of the triple-valve piston; but he provided, as the actuating motor for each discharge valve, a separate or supplementary piston.

The object of the invention of this 1879 local-vent patent (No. 217,838) is thus stated in the specification thereof.

"It sometimes happens with such brake apparatus, especially *in case of accident*, that material advantage could be effected by having *all the brakes of the train applied or brought into action simultaneously, or as nearly so as possible*. To accomplish this it is only necessary to make provision for the *simultaneous opening of one or more ports in the air conduit passages at points not remote from each auxiliary reservoir*" (p. 759, last paragraph.)

The patent describes the accomplishment of this by placing discharge-valves at intervals in the train-pipe, these valves being opened by a *fall of pressure in the train-pipe*, just as in modern practice.

In the course of taking testimony in this cause defendants proved, by the equipment of a rack containing fifty brakes provided with this "quick-action element" of 1879, that these devices were

operative and that the time of full application of all the brakes was reduced thereby to less than half (p. 695. Q. 8.) Exception has been taken by Complainants to the conclusiveness of these tests, and they rely on expert testimony to the effect that the device invented by Mr. Westinghouse, and patented by him in the 1879 local-vent patent as a new and useful invention, was in reality an *inoperative* contrivance. This contention is not established by the testimony, but the controversy need not be pursued here, for the material matter is fully proved by the testimony of Mr. H. H. Westinghouse, who proceeds to describe what was done immediately after the Burlington trials of 1886. He describes, at the bottom of page 123, the operation of the old automatic brake, with its triple-valve mechanism and piston, pointing out that "it is only for *emergency* or quick stops that the final and complete movement of this piston and valve is required." He then says (p. 124):

"Advantage was taken of these conditions to arrange an
 " *auxiliary device* controlling communication between the
 " train-pipe and the *atmosphere*, which was caused to operate
 " *by the final or complete travel of the piston of the triple valve*
 " when a considerable reduction of pressure was made at one
 " end of the train-pipe for emergency or quick stops. With
 " the aid of this device there was a complete exhaustion of the
 " air from the train-pipe at each triple-valve, which accelerated
 " the operation of the brakes *to a degree that reduced the time*
 " *of full application on the last car from twelve seconds to six.*"

Particular attention is called to two facts here stated by Mr. Westinghouse: *First*, that the arrangement by which this result was accomplished employed the old means of *local venting in the form proposed in the 1879 local vent patent*, that is to say, the vents in the train-pipe discharged *to the atmosphere*; *second*, that the auxiliary-valve device which controlled the vent in each brake was "CAUSED TO OPERATE BY THE FINAL OR COMPLETE TRAVEL OF THE PISTON."

Here we have the "final or complete travel of the piston," operating the discharge valve of the 1879 local-vent patent. It would seem quite natural to employ this organ for this purpose, seeing that the office of the piston always has been to operate the valves of the brake mechanism, and one valve, more or less, would seem to make

no great difference; but, as will presently appear, the official tests showed that the piston was not capable of opening the discharge valves with the requisite promptness.

It will be noted that this result, obtained by the means disclosed by the 1879 local-vent patent, absolutely confirms the correctness of Mr. Boyden's conclusions. It is with *this result*, namely, application of all the brakes of a fifty-car train in *six seconds*, that the result obtained by the brake of the patent in suit is to be compared.

The cut opposite this page illustrates the arrangement here described by Mr. Westinghouse. The parts are in all respect like the corresponding parts of the patent in suit, with the exception that the discharge passages, vent to the atmosphere. It will be noted that, when this construction is modified by connecting the end of the passage H which discharges to the atmosphere so that it will discharge to the brake-cylinder, as indicated by dotted lines, the operation of the piston remains unchanged.

This arrangement, in which the "further traverse of the piston" *operates an auxiliary discharge valve permitting air from the train-pipe to discharge to the atmosphere*, does not appear by any evidence in the case to have been the invention of Mr. George Westinghouse, Jr., and we have reason for asserting that no such contention will be made by the other side. It suffices for our purpose that this arrangement is *excluded* from the patent sued on, which is in terms limited to that modification thereof wherein the passage controlled by the auxiliary discharge valve *connects with the brake-cylinder*.

From this testimony we can also get the measure of the distinctive new departure pointed out in the patent sued on, and which is the salient feature of every claim, to wit: leading the passage, through which the train-pipe air discharged at each brake, to the *brake-cylinder*, instead of to the *atmosphere*.

In the next paragraph to that last quoted (p. 124) the witness (H. H. Westinghouse) describes as the next step in the progress of development of quick-action brakes, the invention of the patent in suit, which he appropriately terms a "modification" of the arrangement last described.

The effectiveness of the invention patented in the 1879 local-vent patent to produce the desired effect, *i. e.*, to cause "nearly uniform application of all brakes *practically coincident* with the exhaustion of

Cut of arrangement described by H. H. Westinghouse, whereof the
 Invention of the Patent sued on is a "modification."

air at the forward end of the train-pipe" was experimentally demonstrated before taking any step in the construction of these test brakes. Mr. Westinghouse says (p. 123):

"By placing in the train-pipe at regular intervals a form of delicately adjusted exhaust-valve, it was found possible to cause them to operate by the moderate reduction used in 'service' applications. The operation of these valves caused air to be exhausted from the train-pipe, *wherever they were located*, and their action being *nearly simultaneous*, the effect of their operation was to cause *a nearly uniform application of all the brakes practically coincident with the exhaustion of the air at the forward end of the train-pipe.*"

It clearly appears then that it only remained to determine by trial whether the auxiliary discharge-valves could be opened promptly by the triple-valve piston. What would happen if they were promptly opened was already well ascertained.

The test of the invention of the patent in suit then was a trial of the ability of the triple-valve piston to attend properly to the duty of opening *this new valve*, in addition to the like duties it performed for the other valves.

The witness proceeds to testify (p. 125) that a train of fifty cars was equipped with brakes constructed on the plan of the patent in suit, for the purpose of the second trials, which occurred at Burlington in May, 1887.

Exhaust-valve mechanism was also provided "to be operated by electricity, capable of being inserted in the train-pipe as frequently as circumstances proved necessary." *Two* of these valve devices placed at regular intervals in the brake-pipe, were found to be sufficient to produce an *instantaneous and uniform application of all the brakes of a fifty-car train* (p. 125.)

The results obtained by the system when using the discharge-valves venting to the atmosphere and operated by electricity were, in the words of Mr. Westinghouse, that "*the desired coincidence of operation was secured* and stops were made *without perceptible shock*" (p. 126.)

The official report states that:

"This type of brake possesses four distinct advantages:

"(a) It stops the train in the *shortest possible distance*.

"(b) *It abolishes shocks and their attending damage to equipment.*"

"(c) *It releases instantaneously.*

"(d) *It can be graduated perfectly.*"

On the other hand, the result obtained by the brakes of auxillary-valve patent in suit as compared *with the old automatic* tried the previous year was, in the words of Mr. Westinghouse (p. 126), that—

"the shocks experienced in the preceding year were *greatly exceeded*; reaching a maximum of 103 inches, as compared "with the maximum of 49 inches in the 1886 trials."

The result, in the words of the official report, was to "*leave the field for improvement as wide open as it was in 1886*" (p. 126).

The result in the direction of securing "*the desired coincidence of action*" was that "*the interval of application between the first and last cars of the test train was reduced from twelve to six seconds*" (p. 125). That is to say, the mechanism of the patent sued on did not gain in the direction of securing "*coincidence of action*," which was the one thing "*desired*" after the trial of the old automatic in 1886, *a fraction of a second* over the brakes provided with the old means of venting *to the atmosphere*. Compared with the old automatic *not provided with the quick-action device of the 1879 local-vent patent*, the violence of the shocks was *more than doubled*; and compared with the electrically operated valves *venting to the atmosphere* the former was a complete failure,—the latter a perfect success.

What new result, then, can be justly claimed for this invention? The result which Complainants claim is that *compared with the brakes tried in 1886* it stopped a train in 200 feet instead of in 350. This is extolled in Complainants' brief as a wonderful result, and it is therein ascribed to the venting of air *into the brake-cylinder*. The pertinent fact in this connection is entirely obscured, and a fictitious gain is set up, when in reality there was none at all. The comparison from which this conclusion is drawn was *not* with the old automatic provided with the *existing quick-action means of local-vents in the train-pipe*, but with the old automatic *just as it was constructed for short passenger trains*. To determine the gain in promptness of individual, as well as of serial application, over what had been previously attained, or what could be attained by means then known, the comparison should have been with brakes having local-vents discharging *to the*

atmosphere. By means of these devices, as testified by Mr. H. H. Westinghouse (p. 124) the time required for full application of all the brakes was *six seconds*.

The report of the committee, where it refers to the *shortness of the stop* effected by the brakes of the patent in suit, uses as the standard of comparison *the old automatic brakes tried in 1886*, which contained no provision for acceleration. The report says (p. 128):

"These stops may be considered as phenomenal in their
"shortness, which becomes all the more evident *when we com*
"pare them with the best results obtained in 1886,"

and adds that—

"the brilliancy of this record was *completely spoiled* by the
"fearful shock given at the rear end, the slidometer moving
"it will be observed, from 70 to 103 inches." (P. 128.)

This result, namely, an apparent advantage over a device *not equipped with the known means of local venting to the atmosphere*, and even this dubious triumph, *completely spoiled* by the fearful shocks, is a good enough basis, in the opinion of Complainants' counsel, for a claim of extraordinary merit for the invention of the patent in suit.

But the very next table in the official report of the Master Car Builders gives the result in *quickness of stopping* obtained by the brakes when provided with discharge valves (operated electrically) *venting to the atmosphere*. We find that under the *same conditions* wherein the brake of the auxiliary-valve patent in suit stopped the train in 200 feet, with "fearful shock," the train equipped with the two local vents stopped it in 139 feet, without shock. And the report adds:

"Now comes the still more astonishing story: In these
"electrical stops *the slidometer never moved*, and this with the
"same cars, the same leverages, and the same pressures, the
"only difference being *the time of application*."

We have, then, presented upon the best authority the practical results attained by discharging the train-pipe to the brake-cylinder when using the brake to make a quick stop. In respect of *bringing the train to a stop* the brakes of the patent were phenomenal in their *quickness when compared with the plain automatic-brakes tried in 1886*, and phenomenal in their *slowness* when compared with the same

brakes provided with the local vents discharging to the atmosphere, which vents had quick-acting (electric) motor devices. As to *quick-ening the serial application* of the brakes, the means of the patent in suit gave *exactly the same result as the atmospheric venting-brakes when operated by the same means* (reduction of train-pipe pressure), and results far inferior to the train equipped with electrically-operated vents. As to *shocks*, the invention of the patent more than doubled the violence of the shocks produced by the *old automatic*, which latter had four times the intensity found to be injurious to cargo and equipment, whereas, with the local-vents, the train was stopped without shock great enough to produce any effect on the registering device.

Plainly, then, the claim that this invention is the "pioneer quick-action brake" rests on nothing at all. The invention did not produce a "quick-action brake," nor did it advance the art one hair's breadth towards that result. The gain in this respect *over the old automatic* was due to getting the air quickly out of the train-pipe, (which, with the means for doing it, *was old*), and not in the slightest degree to the use of the air thus discharged in the brake-cylinder. The experiments, as testified by H. H. Westinghouse, showed that precisely the same result in respect of quick *serial* application was produced whether the train-pipe discharged to the brake-cylinder or to the atmosphere.

From these facts we can determine with absolute certainty the *cause* of "quick-action," as produced in the modern air-brakes. That *cause* is the rapid and uniform reduction of pressure in the *entire length* of the train-pipe. *One* of the agencies through which that cause operates in the Westinghouse brake to produce that result we have already seen in the prior art, to wit: local discharge valves in the train-pipe. We have also seen that another co-operating agent was required in order to produce the result by the action of compressed air alone, namely, a *quick-acting motor* for the discharge-valves—a motor that would act with approximately the promptness of the electric actuating devices. When, and in what form this needed agent was devised by Mr. Westinghouse, will shortly appear.

These trials occurred six months after the application for the patent in suit had been filed, and two months after the patent itself issued. The invention was fully matured, and, indeed, there had been abundant opportunity for improvement. Did it accomplish

"the desired consummation," or even give promise of its accomplishment? Mr H. H. Westinghouse says (p. 127) that:

"The beneficial effect of the use of the *electric valves* was so marked that it apparently *seemed to the committee* to be the *only direction* in which to seek for the desired consummation."

The committee were certainly competent judges; but this belief, according to this witness, was generally shared "by those conversant with the subject. He says (p. 129):

"The improvement in respect to the time of application between the first and last brakes was so great between the 1886 and 1887 trials* that it was *not generally believed by those conversant with the subject who witnessed the tests* that a further change sufficiently great could be made to cause the quick-action apparatus to come within the prescribed requirements without the aid of electricity."

The judgment of all who witnessed these thorough trials of the brake of the patent in suit was not only that it did not accomplish quick-action, but that quick-action *could not be accomplished without electricity*. This was the point that was reached when the invention of the patent in suit was fully tested.

THE UTILITY OF THE INVENTION OF THE PATENT IN SUIT.

In demonstrating, as we think has been done, that discharging the train-pipe into the brake-cylinder is not the *cause* of which "quick-action" is the *effect*, we do not necessarily assert that that operation was without *utility*. On the contrary, it had and has utility, as may reasonably be inferred from the fact that it is found in the successful brakes of both the parties to this suit. The utility of this "modification" is said by Mr. H. H. Westinghouse (p. 124) to be, *first*, that it *saved and utilized* air that was *wasted* when the train-pipe was discharged to the atmosphere; and, *second*, that the pressure obtained from the train-pipe for emergency purposes augmented that from

*The change by which this supposed ultimate improvement was effected consisted in putting into use the invention of the 1879 local-vent patent.

the auxiliary-reservoir about twenty per cent.* The first consideration (saving *air*) is paltry in connection with an operation resorted to but rarely, and then only to save lives and property from destruction. The second consideration is more important, as it permitted the braking-power obtained from the auxiliary-reservoir to be *restricted* to that found most suitable for "service"-stops, supplementing that power by the air discharged from the train-pipe in making "emergency"-stops (H. H. Westinghouse, p. 124).

The tests showed that there was no *need* of augmenting the power of the reservoir for this purpose, but the "modification" described by the patent in suit had the advantage that it rendered it *unnecessary* to make provision for such a rapid flow of air from the auxiliary-reservoir as would otherwise be desirable in making an "emergency"-stop. This expedient, then, of directing the air discharged from the train-pipe into the brake-cylinder solved no problem, supplied no necessity, removed no hindrance that stood in the way of "quick-action." It enabled something to be done that was *desirable*, and therefore useful, but which was not necessary to "quick-action," and in fact contributed *nothing at all* to that result.

THE BOYDEN 1883 PATENT.

But it is material to ascertain at this point just how far the demonstrated utility of the invention patented in No. 360,070 in suit had been accomplished previously thereto. At this point attention must be given to Boyden's patent of 1883, No. 280,285 (p. 776) and its precise bearing upon the question under consideration, must be determined.

This patent (which we will call the "Boyden 1883 patent") shows that the brake of the auxiliary-valve patent in suit was not the first in which, *when the piston made its complete traverse*, a passage was opened from the train-pipe to the brake-cylinder, so that air could pass directly from the former to the latter.

*The method of exaggeration employed by Complainants' counsel is exemplified by frequent statements to the effect that, by the patented invention, an emergency passage to the brake-cylinder was opened "through which the *train-pipe* air *in bulk* could pour into that cylinder" (p. 17, italics are in the original). According to Mr H. H. Westinghouse the auxiliary reservoir contributes 80 per cent. of the air and the train-pipe but 20 per cent.

Boyden 1883 Patent.

The piston has made its complete traverse, which opens wide the Main Valve through which both Auxiliary Reservoir Air shown by a Yellow line, and air from the Main Air Pipe shown by a Blue line, pass to the Brake Cylinder—just as in the Defend structure.

The construction of this valve mechanism is shown in the accompanying diagram. It may be regarded as in all respects an ordinary triple-valve, and no explanation of any part will be required except with reference to *the passage through the piston from the train-pipe to the valve-chamber*, in which passage is the check-valve D. The operation of this device is such that, whenever the pressure in the train-pipe *exceeds* the pressure in the valve-chamber, air from the former passes through said passage into the latter; *and whenever the main-valve H is open*, the air thus admitted to the valve-chamber, passes freely to the brake-cylinder. Attention is particularly called to these conditions because they are *precisely those which exist in the Defendants' "quick-action brake."*

Since check-valve D always prevents back flow from the valve-chamber to the train-pipe, the passage in which it is placed is said in the patent to be "always open one way only." This condition is also *exactly duplicated* in Defendants' quick-action brake, so that anything in these respects which differentiates the brake of the "auxiliary-valve" patent in suit, No. 360,070, from the Boyden 1883 patent, equally well differentiates Defendants' quick-action brake from the brake of the patent in suit.

It will further be noted that the passage from the train-pipe to the brake-cylinder is opened when, and only when, the piston has made its extreme movement, moving valve H to such position as to uncover fully passage C leading to the brake-cylinder; in other words, *opening the main-valve*. In this, too, there is perfect coincidence between this Boyden 1883 patent and Defendants' "quick-action brake."

There is no pretense by Boyden that, when he invented and patented this brake, he had any idea of thereby quickening the action of the brake. Doubtless, in the use which is now made in great emergencies of the air admitted directly from the train-pipe to the brake-cylinder, there is *greater utility* in opening a direct passage between these points than in any use which Boyden had in mind in 1883. But he *was the first to open that passage when the piston made its final traverse*, and he is entitled to all the benefits and utilities thereof.* He

* Roberts vs. Ryer, 91 U. S., 157; Potts vs. Creager, 155 U. S., 606.

did it in 1883 without an auxiliary-valve, and he does it now without an auxiliary-valve.

Whatever of merit, therefore, there may be in *opening a passage through the triple-valve from the train-pipe to the brake-cylinder by the final movement of the piston*, that operation was performed in the brake of the Boyden 1883 patent. The argument of Complainants' counsel in this connection is plainly based on an unwarranted and false assumption, viz., that the discharge of the train-pipe *into the brake-cylinder* is the *cause* of quick-action, thus arguing from the assumption that Westinghouse used this old operation to produce a new *effect*, and is entitled to monopolize the operation for *that* purpose. Having shown that the assumed relation of cause and effect *does not exist*, the argument is left without support.

The distinction between this Boyden 1883 patent and that of the auxiliary-valve patent in suit upon which Complainants' counsel mainly insist is that this Boyden 1883 patent is a "non-quick-action brake," and that Boyden did not by that invention discharge air directly from the train-pipe to the brake-cylinder "*to produce quick-action.*" The sufficient answers are that the public official trials in 1887 of the brake of the patent in suit conclusively proved that it was equally a "non-quick-action brake," and that if Westinghouse did in fact discharge the train-pipe into the brake-cylinder "*to produce quick-action,*" (*i. e.* with the expectation that he would thereby produce quick-action) the *purpose* for which a thing is done does not confer novelty upon that thing if it be otherwise old,* particularly if it *failed to accomplish that purpose.*

A fact in this case which largely bears the weight of the charge of infringement is that, in Defendants' "quick-action" brake, the movement of the piston *has something to do with* the admission of air directly from the train-pipe to the brake-cylinder. It will, therefore, be very important to note that the piston in the Boyden 1883 patent has *precisely the same agency in this final result as it has in the Defendants' quick-action brake.* In both its exact contribution to that result is *to unseat the main-valve.*

*Walker on Pats., 3d Ed., p. 182; Crescent Brewing Co. v. Gottfried, 127 U. S., 168.

Finally, it is to be noted that the inherent capacity and law of action of this 1883 device is to admit air directly from the train-pipe to the brake-cylinder whenever a lower pressure exists on the valve-chamber side of the piston than on the train-pipe side thereof and the main-valve is open. What Boyden did to produce his quick-action brake was to provide means whereby this difference of pressure can be momentarily created *at the time when it is desired to effect a quick-stop*. Westinghouse invented no such "means," or agencies for this purpose, or for any purpose.

THE INVENTION OF THE WESTINGHOUSE PATENT

No. 376,837.

Recurring now to the condition of things which existed after the second Burlington trials, as stated by Mr. H. H. Westinghouse, it is clear that what was then needed to make the Westinghouse brake a "quick-action" brake was *a quicker motor device for the discharge-valves of the train-pipe*—something that would produce proximately the effect of the instantaneous electrical-actuating devices. It was conclusively shown by these tests that whether the train-pipe discharged to the atmosphere or to the brake-cylinder was a matter of indifference. One way, equally as well as the other, would accomplish "quick-action," *provided a quick-acting motor could be invented*. That was all that was needed *before the invention of the patent in suit*. It remained *just as much a necessity after the invention of that patent*.

On the production of this *quick-acting motor* for the discharge-valves the great energies and resources controlled by the Complainants were now concentrated "by the direction and under the supervision of George Westinghouse, Jr.," (p. 129.)

The expenses and labors devoted to the solution of this unsolved problem, as described by Mr. H. H. Westinghouse (pp. 130-132), were enormous, occupying the time from the middle of May to the latter part of September, 1887. During that period *"all the resources and employees that could be used were kept at work day and night without cessation*, and the materials for trial each time, involving more than a car-load, were conveyed from Pittsburg to Burlington by express, so that no time might be lost."

The mother, Necessity, was in the throes of labor with a *great invention*. In due course it was brought forth, and it was patented to George Westinghouse, Jr., and became and is the exclusive property of Complainants. There is no pretense that Defendants have employed this invention.

This successful quick-acting motor for the discharge or "auxiliary"-valves, which enabled all the discharge-valves of a fifty-car train to be operated in *two seconds*, without the use of electricity, is the "supplemental-piston" patented in patent No. 376,837, dated January 24, 1888. We shall call it the "supplemental-piston" patent.

It was, therefore, with some justification that the invention of this supplemental-piston patent was hailed as a great invention that overcame great hindrances. It was with some justification that the New York courts held, on the demand of Complainants and on the evidence they produced, that this *later* patent was the "pioneer quick-action brake," was "*the bridge which carried car-builders from failure to success.*" It was, undoubtedly, the patent which produced the agent that was needed to enable the cause of quick-action (local-venting) to produce that *result*.

This view also finds some support in the decisions of this Court. As tersely put in the Barbed Wire Fence case (143 U. S., 283). "*In the law of patents it is the last step that wins.*"

But there is *no* justification here for the assumption that pervades the argument of the other side, and finds expression at numerous points in their brief, to the effect that the invention which accomplished the great result of effecting practically simultaneous application of all the brakes on a train of fifty cars was the invention of the "auxiliary-valve patent in suit."

We have now presented the facts with reference to the results produced by the invention of the patent sued on, and we have stated them with great detail, and *solely from the evidence produced by Complainants*, in order to determine, with the nearest possible approach to certainty, just what basis the evidence affords for the claim that the invention of this patent is "the pioneer quick-action brake." We have from these facts to deduce an answer to the question which Complainants have put in issue and made material, and indeed have made the basis of the con-

tention that the patent sued on should be construed broadly for the method or process of discharging air, by the further traverse of the piston, into the brake-cylinder instead of to the atmosphere. That basis is that it was done "to produce quick-action." They are careful not to say that Westinghouse was the first to discharge the train-pipe to the brake-cylinder, *thereby producing* quick-action; but that is what they wish the Court to infer.

Briefly summing up the material facts with reference to the development of the art to the point of the production by Westinghouse of the "quick-action brake," we find that the old automatic in common use had but one discharge opening for the train-pipe, and that if the pipe were the length of fifty cars it required twelve seconds for the air to escape through that one door. Westinghouse had perceived this limitation, and also the way to remove it—namely, by providing a number of doors along the train-pipe, and he had devised means consisting of *supplemental-pistons* for opening these doors, the pistons being operated by the reduction of train-pipe pressure. All this was in the "local-vent" patent of 1879. When this plan came on trial in 1887 it was found that the actuating devices adopted for opening these doors, by reduction of train-pipe pressure (namely, a mechanical connection with the triple-valve piston,) did not work fast enough. It was also found that, if prompt-acting means for opening the doors could be provided, the plan of local venting would be an entire success on a fifty-car train. Mr. Westinghouse thereupon invented and patented in 1888 the "supplemental-piston" as a means for opening these doors. This proved an entire success.

Thus in the actual development of this art, as shown by the testimony offered by Complainants, the auxiliary-valve *operated by the piston of the triple-valve*, has no place at all. After the 1887 tests none of these devices were ever manufactured or put into use. R. p. 149, L. 36.

IS PATENT NO. 360,070 IN SUIT, A PIONEER PATENT?

The answer to this question is read on the face of the facts stated above, but we have to notice the attempt of Complainants' counsel to read a different answer therefrom. This attempt will be disposed of by applying the following principle, which we submit is the law of the discussion on this point:

The earlier and later patents of Westinghouse and the results attained by them, cannot be considered in this case except for the purpose of limiting and defining the scope of the patent in suit, and for that purpose their effect is practically the same as if they were patents of another person.

How important it will be to apply this principle, if it be sound, will presently appear, and the importance of the principle involved justifies our dwelling for a moment upon it.

The principle is that stated and applied in *James v. Campbell* (104 U. S. 356) and is based on the fact that the merit due to inventions of other patents can only be recognized in suits where such other patents are involved. In this instance the patentee can no more borrow credit from the achievements of his other patented inventions for the purpose of inducing the Court to greater liberality in construing the patent in suit, than he can borrow for that purpose from the inventions of others. The patentee stands before this Court, upon this patent, *precisely as if the invention of the supplemental-piston patent, No. 376,837, had been made by another, or had never been made at all.**

Our proposition is that if the patent in suit were a pioneer, it was such *from the moment it was granted*. Its status and its scope were *then definitely and forever fixed*. These could not possibly depend upon what might or might not be subsequently done by the patentee (or by others) in the near future, or in the remote future. Otherwise we commit ourselves to the absurdity of holding that a patent which is not a "pioneer patent" may subsequently become such in consequence of a later invention, itself the subject of a patent.

*Attention is here particularly directed to that part of the main brief of complainants' counsel which begins at p. 30 under the caption, "THE INVENTION OF WESTINGHOUSE OF THE QUICK-ACTION BRAKE IS A 'PIONEER' INVENTION, OR ONE FUNDAMENTAL IN CHARACTER," and extends to p. 38. Underlying all this argument is the assumption that the credit due to the *later* invention, and the result which it brought about, can be considered in support of the patent here in suit, just as if defendants were charged with infringing the later patent.

This is the proposition which the other side offers to the Court to reconcile their claim of pioneership with the facts demonstrated by the Burlington trials. After a slighting reference to the "defects" of the brake of the auxiliary-valve patent in suit, they argue (p. 37) that, notwithstanding the pronounced inadequacy and failure of the patented invention to produce any advance towards "quick-action," the legal consequences are the same as if the invention had completely solved the problem, because these defects were

"shortly remedied by the same inventor, and so promptly and perfectly remedied that at the time the testimony was taken between 1,500 and 1,800 of these valves were in actual use."

But the remedy invented "by the same inventor," and which made his apparatus a "quick-action brake," was patented to him in No. 376,837, and the facts here brought forward were urged upon the New York Courts, and accepted by the latter as establishing that *this later* patent was the "pioneer quick-action brake" patent. Therefore against the assumptions of the foregoing passage we maintain that whether the successful invention "promptly" followed that which failed, or came only after a long interval; or whether it was made "by the same inventor," or by another, or never made at all, are matters which have no influence whatever in determining the scope of the patent in suit. The results achieved by the *later* invention (No. 376,837) confirm and emphasize our position. The ascertained merit that belongs to *it*, for the production of that which was needed to endow the mechanisms existing *before* the invention of the patent in suit with "quick-action" renders it impossible to ascribe to the latter the merit now claimed for it.

The argument of Complainants' counsel which we are now considering would as readily, indeed *much more readily*, demonstrate that No. 217,838, of July 22, 1879, which disclosed "local-venting" of the train-pipe, was the "pioneer quick-action brake patent." The testimony of Mr. H. H. Westinghouse shows that the quick-action means of this patent reduced the time of application from *twelve* seconds to *six*. This is the means which, with the supplemental-piston of No. 376,837, make the modern quick-action Westinghouse brake; and this means is public property. The auxiliary-

valve patent in suit gave no action quicker by a fraction of a second than this. It was merely a lateral excursion from the true line of development of quick-action—a plunge in the wrong direction—failing to give that which was sought, but giving the incidental advantage of economizing air, and supplementing the power of the auxiliary-reservoir, which had already been done in the Boyden 1883 invention.

Between the local-vent patent, No. 217,838, and the supplemental-piston patent, No. 376,837, there may be a legitimate dispute as to the claim of pioneership. The first disclosed the means for rapidly depleting the pressure of the train-pipe, namely local-venting. The latter disclosed what the former lacked, namely practical means for opening the vents with the requisite promptness. One disclosed the principle and *one* of the agents necessary to carry out that principle in practice; the other made the first effective and successful by supplying the *other* needed agent, thus producing a practical embodiment of the invention. But the patent in suit did neither the one nor the other, nor contributed in the slightest degree to either. It has no shadow or color of right to claim pioneership. It is an impostor, with no merit to support its pretensions to pioneership except what it has wrongfully appropriated from other inventions.*

In 1890, Complainants brought suit against the New York Air-Brake Co. for *infringement of the later supplemental-piston patent*, No. 376,837. Here they found a manufacturer of a "quick-action brake" who apparently did not infringe what is, in this suit, Complainants' fundamental, pioneer, quick-action brake patent, which itself is a significant circumstance. Complainants in that suit had to make a judicious distribution of the merit they claim between these two patents, in such proportion that No. 376,837 should get the bulk of it; and they did so. The deposition of H. H. Westinghouse, from which we have freely quoted, was given in the New York case, and

*Opposing counsel refer in their brief to the Bell Telephone and the Mergenthaler Linotype in illustration of the principle that a great and primary invention need not appear in the patent in a perfected form. It is, however, requisite that the means disclosed by the patent should be *fully adequate to accomplish the intended result*. The difficulty with No. 360,070 in suit was not that the apparatus described was "crude," it was anything but crude. The difficulty was that it lacked, *just what the local-vent 1879 patent lacked*, means for promptly opening the vents through which the air could escape from the train-pipe.

from that and all the evidence, the Court was convinced, and so adjudged, that the later patent disclosed the meritorious, primary invention that resulted in the "quick-action brake," and was the pioneer patent. The Circuit Court of Appeals (by Judge Shipman) said:

"The patentee was a pioneer in that he designed in No. 376,837 a new way to accomplish a desired result, but upon the same general idea that he had *unsuccessfully* tried to work out in the earlier patent. His *later patent was the BRIDGE, and not a mere step, which carried car-builders from failure to success.*" (63 F. R. 969.)

Afterwards the Defendants in New York changed their construction and were sued under No. 360,070, the auxiliary-valve patent in suit. Then a redistribution of the merit became necessary, and Complainants were equal to it. But the Court having held that No. 376,837 was the *whole bridge*, could not ignore that conclusion, and hence in the last decision, Judge Lacombe, referring to the previous adjudications, says:

"In these opinions it is held that the two patents, 360,070 and 376,837, disclosed one the emergency-valve, the other the supplemental-piston or special motor, which so far as the art has now progressed, appear to be *both essential* to the *structure* of a successful quick-action brake.* Both these inventions achieved great necessities and overcame great hindrances; each is an *INDISPENSABLE* part of the bridge which carried car-builders from failure to success." (65 F. R. 100.)

In the present suit it is necessary to put forward the earlier auxiliary-valve patent No. 360,070, as *the bridge*, the supplemental-piston patent being introduced casually in the brief as "a subsequent and in some respects *less important* invention of Westinghouse," (p. 33); and the merit is *again* redistributed, going this time in bulk to No. 360,070, in suit.

*Judge Lacombe evidently was not aware of the construction of the Boyden Brake, which employs neither an emergency or auxiliary-valve nor a supplemental-piston or special motor. Since Boyden admittedly does not use the latter it is manifest that he produces the same result (quick action) by means different from those of Westinghouse, for he at least omits what in the latter cannot be dispensed with.

Complainants have thus, at different stages of their litigation, assumed three different positions upon this question of pioneership. First they convinced the Circuit Court of Appeals (Second Circ.) that No. 376,837 was the genuine pioneer. This "*later patent*" they held was "*the bridge on which car-builders crossed from failure to success.*" Afterwards they secured judicial sanction to the proposition that "*each was an indispensable part of the bridge.*"

Either of these propositions would be fatal to the pretensions here, for they cannot charge that Defendants have used the invention of the later patent, which was first the *whole bridge*, and afterwards an *indispensable* part of it. Acceptance of either of these propositions would carry us at once to the conclusion (which by patience will be reached with certainty) that Mr. Boyden crossed *on a bridge of his own*, using what was public property to carry him as far as it would go, and adding, by his own inventive genius, what was required to complete it.

In this suit then, Complainants take their third position, which is that the auxiliary-valve patent in suit is the *genuine* pioneer, the *real* bridge, and that No. 376,837 is neither *the bridge* nor an *indispensable* part of it, but merely a matter of decoration or architectural embellishment.

In establishing two of these contentions, Complainants have succeeded. If they succeed in establishing the third, it will be one of the most remarkable results ever attained by legal ingenuity.

We feel justified in concluding from the foregoing that the auxiliary-valve patent in suit, No. 360,070, is *not* the pioneer patent for "*the quick-action brake.*"

If, then, the broad interpretation which Complainants ask of the patent in suit depends upon the benefit of a rule of interpretation applicable solely to "*pioneer patents,*" the question propounded by the Court is already answered.

But it may be said that, conceding this invention to be not of "*primary*" character, and that it failed completely to accomplish that for which it was solely designed, nevertheless the novel means it disclosed and which produced a result of *some* practical utility may afford the basis for a claim to a process or method, or to some broad means, which claim may be infringed by Defendants. This question will

therefore be considered independently of the question of pioneership, but with reference to the terms of the patent and to the prior art.

CAN PATENT NO. 360,070 IN SUIT BE SUSTAINED AS TO PROCESS OR METHOD?

The effort is to construe Claim 2 as for a process or method of admitting air directly from the train-pipe to the brake-cylinder when that operation is in some manner brought about by the further traverse of the piston. The operation is itself old, but the contention is that it is new to do it by the particular means specified, to wit, by the further traverse of the piston.

The claim is as follows:

"2. In a brake-mechanism the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder, substantially as described."

The proposition that a process, which consists in doing a certain thing (itself old) by a particular means or agency, is patentable under the law, has been frequently passed upon by this Court. Thus in *Corning vs. Burden* (15 How., 252), the claim was for "the preparing of the puddlers' balls * * * by causing them to pass between a revolving cylinder and a curved segmental trough adapted thereto."

The claim was in form for a process performed by particular agents, and the Circuit Court held that it was for "a new process of converting puddlers' balls into blooms." But this Court held that the novelty of the invention resided in the *mechanism* employed."

In *Crescent Brewing Co. vs. Gottfried* (127 U. S., 168), the claim was for—

"the application of heated air under blast to the interior of casks *by means* substantially as described and for the purpose set forth."

The Court held that this was "a claim for *mechanism* and not a claim for a process." And the Court distinguished from *Lawther*

vs. Hamilton, showing that the latter gives no countenance to claiming as a process the doing of a particular thing by a particular agent.

In each of the foregoing cases the agent specified in the claim was in fact that *which performed the particular operation claimed as a process*. Claim 2 of the patent here sued on is peculiar in that the operation attributed to the further traverse of the piston is not performed by that device at all, but by an auxiliary-valve and conduit.

If Westinghouse had, in fact, invented a new means for admitting air direct from the train-pipe to the brake-cylinder (this operation being itself old), and such means were the *piston*, he could undoubtedly have a patent broadly for those means; but even then he could not have a patent for the process of doing it *by means of the piston*.

An attempt is made in this claim to go beyond everything of which the reports give an account, and to claim the admission of air direct from the train-pipe, whenever the further traverse of the piston *plays a part* (however remote) in *actuating the real air-admitting devices*. This interpretation, by *ignoring and excluding* the real means by which the train-pipe air is admitted to the brake-cylinder, makes it *impossible to apply to the claim the uniform test for infringement*—the test which is applicable to patents of all grades, and was applied, for example, in *Morley Machine Co. vs. Lancaster (infra)* that test being, in the language of that decision, that “*each mechanism, individually considered, is a proper equivalent for the corresponding mechanism in the Morley patent.*”

In other words, the test sanctioned and uniformly applied by this Court requires us to find in Defendants' machine the “proper equivalent” of the “corresponding” air-admitting devices of the patent in suit. The interpretation of Claim 2 now under consideration says we shall do nothing of the sort, but shall adopt a new test, namely, whether in Defendants' machine some *one* of a train of mechanisms which *actuates* the air-admitting means, corresponds with a selected *one* of a train of actuating agents in the patent sued on.

We do not think the Court will accept this novel substitute for the settled rule of infringement; but if it did, the patent could not live under it, for this test would prove identity between Complainants' patent and the Boyden 1883 patent, in which the final traverse of the

piston has exactly as much to do with the admission of air from train-pipe to brake-cylinder as it has in Defendants' brake.

We could with equal propriety take for our test of identity the question whether, in the two cases, the engineer's valve has anything to do with the discharge of the air as specified, and argue that resemblance in such points establishes identity.

THE VICE IN CLAIM 2.

It is impossible for the mind to dwell long upon the terms of this claim without the conviction that there is *something* wrong with it, and that this entire litigation, with all its deplorable consequences, is directly due to the presence in the patent of a claim about the meaning of which it is possible to wage such tedious controversy, and which this Court is unable to interpret to its satisfaction after all the argument, explanation and illustration that have been lavished upon it. This in itself shows that the claim is not *specific* and *distinct*, as the law requires.

Can we not locate and identify the cause of this extraordinary difficulty? At least we will endeavor to aid the Court by offering the result of our efforts in this direction.

When the statute requires that a patentee shall "*specifically point out, and distinctly claim*" the novel means whereby he accomplishes his result, it calls upon him to state the *immediate or proximate cause* of the described effect, and the law is not satisfied by a statement of a *remote* cause. Even when the invention is of such breadth that it can be expressed in a general phrase, such as "feeding devices," "spacing means," or "sewing mechanism," * the general term specifies *that agent which DIRECTLY performs the indicated operation*—that is, the means which do the feeding, the means which do the spacing, and the means which do the sewing. A claim so expressed, though of the most extreme breadth, distinctly points out the *necessary elements* to be compared with other machines, in which the presence or absence of "*corresponding*" devices for feeding, spacing, and sewing, operating in the same way and performing respectively the same result, determines infringement or non-infringement.

* *Morley Machine Co. vs. Lancaster*, 129 U. S. 273.

Had Bell claimed transmitting articulate sounds *by means of electricity*, his claim would have been void, notwithstanding that he was *the first to accomplish this result by this means*, because he would then have specified the *remote* cause, and not the *proximate* cause. His claim was sustained because he specified his direct means, to wit, "an undulatory current corresponding in form to the sound waves."

Claim 2 of the patent in suit is vicious in that it ignores *the means which admit air directly from the train-pipe to the brake-cylinder*, and instead recites a movement of the piston which more or less remotely *assists in actuating* the air-admitting devices. Had the patentee claimed (as he did in other claims) his air-admitting means, as broadly as the state of the art allowed, the question of infringement would present no serious difficulty. But instead of thus doing in claim 2 what the law requires of him, he has confused and well-nigh baffled inquiry by attributing to the *piston* an office, operation, or action which it does not perform.

This explanation of the extraordinary difficulty which the construction of this claim has given to all the courts that have attempted to construe it*, and to all the counsel who have attempted to elucidate it, will more strongly commend itself to this Court when we come to compare the invention of the patent with Defendants' brake.

We therefore submit that the patent cannot be sustained "as to process or method" first, because the nature of the invention—of the result accomplished, and of the means that are employed therein—do not admit of interpreting the patent as for that process or method which is sought to be based on claim 2.

THE TERMS OF THE PATENT IN SUIT.

But the "terms of the patent," including the terms of this claim, equally preclude such interpretation of the invention, particularly with the light afforded by the proceedings in the Patent Office, and by the prior art. The patent expressly defines the extent of the novelty as consisting of certain "additional members," and specifies these additional members as the by-passage and auxiliary-valve. The specification nowhere hints or suggests that the inventor has discov-

*Judge Morris construed it as for a function, Judge Lacombe as including the auxiliary-valve, and Judge Hughes as "fatally defective" because lacking the essential elements.

ered a new sort of *piston*, whose novelty consists in that by one movement it admits air from one source and by another movement admits air from another source. There is no new sort of piston described, but *per contra* that member, in the minutest detail of its construction, is *identical with the pistons of the prior art*. The piston and its relation to the auxiliary-valve are correctly described, the former being presented as *one of a series of agencies through which the auxiliary-valve is actuated*.†

This accords perfectly with the known history of the invention. When Mr. Westinghouse sought to quicken the action of his old automatic-brake, he took that apparatus just as it is described in expired patent No. 220,556 (the old automatic triple-valve), and *added to it*—not a *new piston*, or a piston endowed with new characteristics, powers or functions—but a *new valve and a new conduit leading from the train-pipe to the brake-cylinder*. When we seek the novel means with a view to giving the inventor *those means and everything that is the equivalent thereof*, shall we not look to *what he added to the old structure*? Or shall we look to what was there before, and remains without a shadow of change in structure or function? In the case before us, whether we add the *new members*, or take them away, it works no change in the *piston*. The latter, in either case, makes its preliminary and further traverse, and the further traverse in either case displaces the old stem 36 and does nothing more.

We may now clearly see the *non-sequitur* involved in Complainants' argument. The office of the piston always has been to operate the valves of the triple-valve mechanism. If every time a new valve is added and mechanically operated by the piston it can be said that the piston performs a *new operation*, namely, *the operation performed by that new valve*, for precisely the same reason it can be said that the variation of train-pipe pressure performs that new operation, or that the engineer's valve performs that operation. Thus by adding a new port and valve to the triple-valve we have the foundation for saying that each one of these agents "performs a new operation," and we have as many *new processes* as there are agents in the series.

† To support the conclusion here stated we refer the Court to the specification of the patent itself which we have printed in colors at the end of this brief, with an analysis of its contents.

On the contrary, we submit the fact is as clear in respect of the piston as of each of the other old agents, that it performs no new function or operation at all, and that the agent of the new operation is that which was added to the old structure for the express purpose of performing it.

THE PROCEEDINGS IN THE PATENT OFFICE.

The meaning of the terms of the patent is, we think, unmistakable; but additional confirmation, if it be needed, will be found in the file-wrapper of the application (p. 706 *et seq.*).

Original Claim 1 (p. 714) was for the ordinary brake elements combined "with a *device* for admitting air directly from the main air-pipe to the brake-cylinder." This was rejected on Boyden's 1883 patent, cancelled, and present Claim 1 substituted (p. 717). This claim reads:

"1. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder, a triple valve, "and an auxiliary-valve device, *actuated by* the piston of the "triple-valve, and *independent of the main-valve* thereof, for "admitting air in the application of the brake, directly from "the main air-pipe to the brake-cylinder, substantially as "set forth."

By the differentiations between the cancelled and substituted claims, attention was directed specially to the salient features of novelty as being the *addition* to the triple-valve of "an auxiliary-valve device," "*independent of the main-valve*," and "*actuated by* the piston."

When confronted with Boyden's patent, Mr. Westinghouse did not say, as his counsel now say, "my invention consists in a piston which is new in that it does something which the piston of a triple-valve never did before," but on the contrary he specifies with great precision his novel means for admitting air from the train-pipe, to wit, an auxiliary-valve device independent of the main-valve, and he specifies the true relation between these means and the piston, saying that the auxiliary-valve is "*actuated by* the piston." The piston then is not the new air-admitting means, but is merely the actuating device for the air-admitting means.

Claim 2 had also been rejected on Boyden's patent, and the inventor was called upon to point out an essential and patentable distinction. We quote this claim again :

" 2. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, and a triple-valve having a piston
 " whose preliminary traverse admits air from the auxiliary-
 " reservoir to the brake-cylinder, and which by a further
 " traverse admits air directly from the main air-pipe to the
 " brake-cylinder, substantially as set forth."

Having put before the examiner a claim (new claim 1) in which the novel air-admitting means (the auxiliary-valve independent of the main-valve) conspicuously appeared, so that it was prominent in the examiner's mind, the inventor proceeds to argue upon both claims ; and in discussing *Claim 2* says :

" When, however, the triple-valve is *provided with an auxiliary-valve operated by its piston*, which performs a new function *additional to that of the triple-valve as previously employed*, " it is believed that *such combination* is wholly novel."

This virtually says to the office and to the public, " my claim extends to the use, additional to the triple-valve as previously employed, of an *auxiliary-valve*, operated by the piston. Outside of those limits every one is free from every assertion of claim under this patent."

Upon this construction of the claim the patent was granted to him, and under well-settled principles this precludes the patentee from asserting, and the Court from adjudging, that this claim covers the *process* of admitting air directly from the train-pipe to the brake-cylinder by a further traverse of the piston.

Sheppard vs. Corrigan, 116 U. S. 593.

Sutter vs. Robinson, 119 U. S. 530.

Roemer vs. Poddio, 132 U. S. 317.

Crawford vs. Heysinger, 123 U. S. 589.

Corbin Lock Co. vs. Eagl Lock Co., 150 U. S. 38.

Before the grant of the patent, moreover, the inventor inserted the following disclaimer (p. 720) : *

* See paragraph printed in green ink on folder at end of brief.

"I am aware that a construction in which 'an always open "one way" passage from the main air-pipe to the brake-cylinder is *uncovered* BY THE PISTON OF THE TRIPLE-VALVE "SIMULTANEOUSLY WITH THE OPENING OF THE PASSAGE FROM "THE AUXILIARY-RESERVOIR TO THE BRAKE-CYLINDER, has been "heretofore proposed, and such construction, *which involves "an operation different from my invention*, I hereby *disclaim*."

This effectually disclaims, not only the Boyden brake of 1883, but Defendants' quick-action brake, and particularly *that office of the piston of the latter which is now pointed to as constituting identity of Defendants' brake with the subject-matter of claim 2*. Defendants' brake, as we will presently see, admits air directly from the train-pipe to the brake-cylinder by the same "always-open-one-way passage," which is "*uncovered by the piston of the triple-valve simultaneously with the opening of the passage from the auxiliary-reservoir to the brake-cylinder,*" and the piston in Defendants' brake does nothing more than or different from this.

What complainants' counsel have contended for in this case is that a construction, in which a "passage from the main air-pipe to the brake-cylinder is uncovered by the piston of the triple-valve simultaneously with the opening of the passage from the auxiliary-reservoir to the brake-cylinder," is identical with the invention of the patent in suit. The patentee himself says in his specification that such construction is old (as it is), that it involves "an operation *different from*" his invention, and that he *disclaims it*.

THE PATENT CANNOT BE SUSTAINED AS TO PROCESS OR METHOD IN VIEW OF THE PRIOR ART.

Discharging the train-pipe to quicken the successive application of the brakes was not new, (Westinghouse 1879 local-vent patent). Discharging the train-pipe to the brake-cylinder simultaneously with the admission thereto of air from the auxiliary-reservoir was not new, (Boyden's 1883 patent). These are the only operations involved which could conceivably be processes. Neither is claimed. Effecting the discharge of the train-pipe by the movement of the piston is excluded from the patent, the modification which

claim 2 includes being that in which the end of the train-pipe discharge passage connects with the brake-cylinder. This is purely a matter of structure. Discharging the train-pipe to the brake-cylinder "*to produce quick-action,*" defines an operation with reference solely to the object sought thereby. This qualification would not confer novelty on an old operation, even if the stated object had been attained thereby, which was not the case.

The interpretation which this patentee himself put upon the prior art in preparing and prosecuting his application for the patent in suit, is specially significant because of his peculiar and accurate knowledge of that art. Being thoroughly conversant with that art particularly as developed by his own previous inventions, he made no pretense of any novelty in process or method, or in the operation of the piston, but set forth his invention as consisting simply of certain specific mechanism, whereby the old operation of locally discharging the train-pipe, and the other old operation of admitting air from the train-pipe to the brake-cylinder simultaneously with air from the auxiliary-reservoir when the piston made its full movement, were effected. The peculiar language of claim 2 offers no contradiction to this, for the attorney who drew it construed it to the Patent Office as a "combination" of the old triple-valve with "an *auxiliary-valve,*" operated by the piston, the latter thus preforming an additional office, that is, opening another valve *additional* to those of the triple-valve, as previously employed.

The specification sharply draws the line between his previous inventions and the new "structural features" disclosed by the patent in suit; but not being so familiar with the inventions of others, the patentee evidently thought he was entitled to claim the combination with the old brake elements of *any* "device for admitting air directly from the main air-pipe to the brake-cylinder" (original claim 1). When, however, attention was called to the Boyden 1883 patent, Westinghouse promptly struck out this claim and expressly stated that his new means consisted in an "auxiliary-valve," and specifically in one that was "*independent of the main-valve.*"

No suggestion that he invented in 1886 a new process or method, or any new operation of the old piston, nor anything capable of bearing that interpretation, ever proceeded from this patentee or

from those who represented him, until such a contention became necessary to support the charge of infringement in this case.

Because then of the state of the prior art, because of its own terms, and because of the proceedings in the Patent Office, the patent sued on cannot be sustained as to process or method.

To these reasons we will add another which will be briefly discussed hereafter, namely, that the patent cannot be sustained as to process or method under the settled law of this Court.

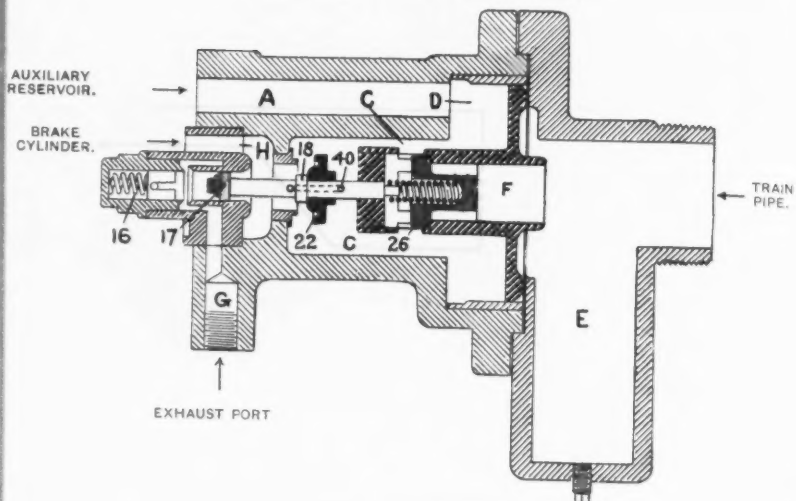

INFRINGEMENT.—DEFENDANTS' STRUCTURE.

We have seen how Westinghouse converted the automatic brake of expired patent No. 220,556 (the old automatic triple-valve) into a quick-action brake by adding to it the means for quickly depleting the train-pipe disclosed in expired patent No. 217,838, (*i. e.*, discharging the train-pipe under each car); and that the modern Westinghouse quick-action brakes, in their broad features, comprise a combination of the devices of these two patents. We have seen that, in bringing these two things together, Westinghouse first attempted to find their practical embodiment by *adding* to the mechanism of the old triple-valve of No. 220,556, an auxiliary-valve, and leading the passage controlled thereby to the brake-cylinder, operating this valve by the further traverse of the piston; that the second Burlington tests demonstrated that this invention did not supply the one thing needed, to wit, a quick-acting motor device for actuating the discharge (auxiliary) valves; that thereafter Westinghouse abandoned the use of the piston of the triple-valve as an actuating device for the discharge-valves, and substituted a new motor device, to wit, a *supplemental*-piston, which was patented to him in a later patent, No. 376,837.

We have now to show, as a matter of fact and history, how Mr. Boyden, starting also from devices existing previously to the invention of the patent sued on, developed a "quick-action brake" by means of an invention which made it *unnecessary* for him to invent or to employ, either an auxiliary-valve operated by the piston, as unsuccessfully attempted in the patent sued on, or a supplemental quick-acting motor for the auxiliary-valve, as successfully done in

**The Old Poppet Form of Triple Valve 1873
incapable of Quick Action.**

Defendants Structure.

**The Old Poppet Form of Triple Valve, made capable of Quick Action
by inserting Boyden's Partition 9.**

In the upper cut the structure operates as a plain Triple Valve, the Main Valve 22 admitting only Auxiliary Reservoir Air to the Brake Cylinder as shown by the Yellow line, & in the lower cut the structure operates as a Quick-Action Valve. The Main Valve 22 admitting both Auxiliary Reservoir and Train Pipe Air to the Brake Cylinder as shown by the Yellow and Blue lines.

This great transformation in the operation being due to inserting the partition 9. With it, the Defendants Structure is a perfect quick-action device without employing any additional or "Auxiliary Valves" in any form, or their mechanical equivalents.

No. 376,837, or any equivalent for either of these devices, both of which are "*indispensable parts*" of the Westinghouse quick-action brake. This invention of Mr. Boyden develops latent but inherent capacities in the old triple-valve brake mechanisms, *leaving every moving part thereof exactly as it was before the patent in suit.*

What Mr. Boyden added to the old and common triple-valve mechanism was a stationary partition, separating the triple-valve chamber from the piston-chamber, this partition having through it an always-open passage of small cross-sectional area.

This simple structural change, *which added no new moving part, and altered no old moving part*, introduced into the old triple-valve a *new mode of operation, which we will now explain.*

The annexed cuts show the construction of Defendants' brake, and we will first briefly point out those parts which correspond in construction and operation with the old triple-valve mechanism (upper cut).

The feed-in valve 26, colored blue, is of the check-valve form, covering an opening through the piston to the valve-chamber. This form of valve is shown in Westinghouse patent No. 144,006 (p. 740), as well as in the Boyden 1883 patent. The main-valve 22 (black) is of the poppet form, and the release-valve 17 (green) is carried on the prolongation of the piston stem, the mechanism being in respect of these two valves like the Westinghouse patent, No. 141,685 (p. 736). The main-valve is provided with the sensitive-graduating valve (yellow) in the form of a passage in the sliding stem.

As thus constructed the apparatus operates in all respects like the old automatic triple-valve 220,556; that is to say, on a partial traverse of the piston the release-valve is closed, and the graduating member of the main-valve moves to a position which admits air gradually from the valve-chamber to the brake-cylinder through the main-valve port. Successive slight variations of pressure in the train-pipe admit additional volumes of compressed air as desired. On the further traverse of the piston the main-valve 22 is raised from its seat, opening more widely the main-valve port and admitting a greater volume of air from the valve-chamber to the brake-cylinder. Thus far the operation is identical with the old automatic triple-valve patent No. 220,556. The valve-chamber is, of course, con-

stantly replenished from the auxiliary-reservoir, with which it has free communication.

The new departure in structure which the lower cut exhibits consists in the presence of a partition or stationary diaphragm, 9, which separates the valve-chamber from the piston-chamber, communication between the two, however, being always maintained through the small passage B. This departure may be accurately described as a contraction in the valve-chamber, leaving a free but contracted channel of communication to it from the piston-chamber.

Close attention is now asked to what new thing happens by reason of the presence of this partition or contraction.

In making "service"-stops the devices operate exactly as before, and with the same results, air passing from the valve-chamber to the brake-cylinder through the main-valve port by reason of the movement of the graduating (yellow) valve.

In making "emergency" stops, the piston makes its further traverse as before, the main-valve 22 is unseated as before, and air passes more freely from the valve-chamber to the brake-cylinder, as before. There is no new operation of any sort, certainly *no new operation of the piston*. But auxiliary-reservoir air cannot now *get into* the valve chamber so freely as it did before, because the passage from the auxiliary-reservoir has been *contracted* by partition 9. Still there is no new operation of any part. The effect is that the pressure in the valve-chamber suddenly falls to, say, about five pounds. Consequently the feed-in-valve opens and admits air from the train-pipe to the valve-chamber. This is what this form of feed-valve always did when these conditions existed. There is no new operation here.

The *new* thing that Boyden has done is to cause this old operation of the feed-in-valve, with the old effect of admitting air from the train-pipe to the *valve-chamber*, to take place *at the time he wanted it to take place*; and this he did by a structural change (inserting a partition 9) of a stationary part of the old triple-valve mechanism, which change is not suggested in the Westinghouse auxiliary-valve patent in suit, nor by anything in the prior art. The conception is in the highest degree original, whereas the means or additional members which Westinghouse employed to produce *his* quick-action brake, to wit, the relief-ports, the

auxiliary-valves therefor, and the supplemental-pistons for operating these valves, are *all* found in the prior art. Only the by-passage leading to the brake-cylinder is new, and if the passage in Defendants' brake *through the valve-chamber* corresponds with that, it is anticipated by the Boyden 1883 patent.

The latter patent gives us, by comparison, the exact measure of the new departure in mechanism or means, and in mode of operation, which the invention of Mr. Boyden introduced. In this old patent we find the feed-in-valve in the same position, operating by the same agency (relative fall of pressure in the valve-chamber) to produce the same effect (admission of air from the train-pipe to the valve-chamber). We also find this operation occurring under the same conditions, that is, when the main-valve is open establishing communication between the valve-chamber and the brake-cylinder, and we find the same effect, namely, a passage opened from both train-pipe and auxiliary-reservoir *through the main-valve port*.

There is absolutely no difference, except the great difference of means for *producing at the desired moment* a relatively great fall of pressure *in the valve-chamber*. This difference of pressure did only what it did before, but the means for producing it is new. This new means is the *agency*, by which Boyden obtained—not a new operation or effect—but an *old* operation at a particular time.

Thus the desired result—"quick-action,"—was attained by means, agencies and operations of which such as *did not exist in the art prior to the patent in suit*, were devised by Boyden himself, and were not suggested in the patent in suit, and have no correspondence with the new means or operations described therein.

The process of causing a fall of pressure on one side of the piston (the train-pipe side) to produce A FAR GREATER FALL OF PRESSURE ON THE OPPOSITE SIDE THEREOF, thereby causing the customary operation of the feed-in valve to produce the customary effect, constitutes the essence of the novelty of the Boyden brake, and between it and the novel means and operation of the patent in suit there is no correspondence whatever. On the contrary, while the vital thing in Defendants' brake is the production of much lower pressure in the valve-chamber than in the train-pipe, it is essential in Complainants' brake that the pressure in the valve-chamber should exceed that in the train-pipe; otherwise it will not operate.

This striking difference in essentials emphasizes the fact that the brake of Defendants appropriates *nothing* from the patent in suit.

VALVE 22 NOT THE AUXILIARY-VALVE OF THE PATENT IN SUIT.

One of the contentions of Complainants has been that the small graduating-valve of the Boyden brake is in reality the main-valve, and that the valve 22 is the "auxiliary"-valve. This theory has been so thoroughly handled, and (as we think) disposed of, in former arguments, that we will give it but brief notice. On this *question of fact* both the lower Courts have found against this contention, and we think this Court will not reverse these concurrent findings.*

The argument of Complainants on this point is that valve 22 is not the main-valve of the old triple-valve, but is an "auxiliary"-valve, because, like the auxiliary-valve 41 of Westinghouse, it opens *only for emergency*, and then like the latter it admits train-pipe-air to the brake-cylinder.

The construction of Defendants' brake in respect of the main-valve and graduating-valve is *exactly* that of claim 1 of the old automatic triple-valve patent No. 220,556 (p. 766), as follows :

"1. In combination with the piston and stem of a triple-valve, a valve, H, arranged on said stem, and having a "short range of motion independent of such stem, in combination with an *auxiliary-* (sensitive graduating) valve "*operated by the same stem to close or open a port through the main-valve, without necessarily moving the main-valve,* "*substantially as set forth.*"

This combination is now *public property*

The unanswerable objections to this contention, briefly stated, are :

(1) That the valve 22 does not open *only* for emergency, nor, when it does open, does it admit train-pipe-air *only*. It will open whenever the pressure in the train-pipe is lowered to the proper degree, regardless of whether the pressure is lowered rapidly enough to open the feed-in-valve and admit

* This Court has repeatedly held that it will not reverse the concurrent findings of two inferior Courts on a question of fact unless the error be clear. *Wiscart vs. Dauchy*, 3 Dall., 321; *Lemmers vs. Nissen*, 154 U. S., 650.

train-pipe-air to the valve-chamber. When it does open it is not to admit train-pipe-air, but *any* air that is in the valve-chamber. In *all cases* it admits air from the auxiliary-reservoir. Conspicuously in the case of breakage of the train-pipe it opens *to the fullest extent without admitting any train-pipe-air at all*.

(2) The valve 22 and its subordinate member, the graduating-valve, act exactly as in the old automatic triple-valve patent No. 220,556, the latter opening for service-stops, the former for emergency-stops.

(3) It is obvious from inspection of the drawing of the Boyden brake, and was conclusively shown by trials at the last argument, that *when partition 9 is removed* the device becomes a plain ordinary triple-valve without quick-action, and the valve 22 is *then* beyond dispute the *main-valve*. If so, it remains the main-valve when the partition is inserted.

(4) The "main"-valve is *always* that valve which controls the passage from the *valve-chamber* to the *brake-cylinder*. This valve has nothing to do with admitting air *to the valve-chamber*. The feed-in-valve always attends to that. Therefore, when the main-valve opens it can only do one thing, namely, admit air from the *valve-chamber* to the brake-cylinder. Hence, valve 22 is the main-valve and not an *auxiliary-valve*.

The identification of valve 22 of Defendants' brake as the "auxiliary"-valve is a necessary part of the theory of infringement which Complainants originally attempted to establish, and which is developed by their expert in their *prima facie* proofs. It is on this theory that infringement of claims 1 and 4 was urged. It appears to us that no further discussion of these claims, or of this theory, will be required by the Court. We expect to satisfy the Court not only that claim 2 is not infringed, but that no claim could be based on the invention of the patent sued on that would cover Defendants' quick-action brake.

THE COINCIDENCES BETWEEN DEFENDANTS' QUICK-ACTION BRAKE AND THAT OF THE PATENT IN SUIT
EXTEND ONLY TO FEATURES THAT WERE OLD.

"*Infringement*" consists in the unauthorized use of the NOVEL means described and CLAIMED by the patent sued on. The term "means" does not ignore equivalents, but embraces them, for the equivalent of a thing, in the eye of the law, is "*the same as the thing itself*."*

The conclusion that infringement has not been committed by Defendants in this case follows from the fact, already elucidated, that the essential *new* thing in the brake constructed by the latter, and to which its character as a "quick-action" brake is directly due, is radically different from the *new* features of the patent in suit to which the results it accomplished (which was not "quick-action") were due.

But the examination of the case would not be satisfactory if it did not fully disclose the reasons why, notwithstanding the contrary bearing of the facts, it has been possible to make a respectable showing in support of the contention that infringement has been committed.

We have already shown that this contention has been largely supported by erroneously identifying the discharge of the train-pipe into the *brake-cylinder* as the *cause* of "quick-action," the fact being that the venting of the train-pipe at different points is the *vera causa*, and that the "modification" consisting in connecting these vents with the *brake-cylinders*, though it may have rendered the action of the system as a whole more efficient, was not in any sense the *cause* of "quick-action."

The contention of infringement has been further supported by the fact that between the device of the patent in suit and that of Defendants there are certain coincidences, or points of resemblance. That this fact does not lend the least support to the conclusion urged is fully shown when we have ascertained that the features, in respect of which the two structures resemble each other, were *old*, and that their operation and action have to do with the *ordinary* service of the brake, and not with that *peculiar and special* service which is called "quick-action."

* "Authorities concur that the substantial equivalent of a thing, in the sense of the patent law, is *the same as the thing itself*."

Machine Co. vs. Murphy, 97 U. S. 120.

One method of demonstrating this is to remove from each brake those features to which this peculiar service is due, and to note that *all* the features of *resemblance* between the two remain without change in structure or mode of operation.

Another method is to examine these resemblances in the two structures and to note that they do not reside in the novel features of construction and operation disclosed by the patent in suit. This latter method remains to be applied.

The resemblance to which Complainants' counsel draw the mind of the Court is that in Defendants' brake, as in the patent in suit, the further traverse of the piston preceeds the discharge of the train-pipe into the brake-cylinder, and in both this movement of the piston is one of a train of operations which has for its effect to actuate the means which admit air from the train-pipe to the brake-cylinder. This resemblance admits of use to support the charge of infringement of claim 2, because that claim, as already pointed out, suppresses the air-admitting means and leaves identity to be determined by resemblance in some other particular.

We are therefore to look for identity in the agencies which operate the discharge-valves. If those agencies comprise a series it is manifest that a resemblance in one or more members does not necessarily constitute identity of the series, and that if it be allowable to designate one of these members as *the* actuating device, instead of specifying the entire series, we would be compelled to select that member which is the *primary* agent.

In the present instance this primary agent is plainly the engineer's-valve, and if it be permissible to interpret the patent by this method, claim 2 should clearly read as for the combination with the ordinary automatic brake-mechanism, of an *engineer's-valve* whose "preliminary-traverse admits air from the auxiliary-reservoir to the brake-cylinder, and which by a further traverse admits air directly from the train-pipe to the brake-cylinder." There is as good, or better, justification in the invention for a claim so drawn as for the claim we are discussing, for this is precisely what happens if we indulge the vice (heretofore pointed out in respect of claim 2) of ignoring the proximate or direct cause of the specified effect, and substituting a remote cause. If the claim had been drawn in this way, it would be plainly seen that it was "fatally defective" in not

distinctly pointing out and claiming, as the law requires (section 4888, R. S.), the part, improvement or combination constituting the invention. The reason why the less justifiable designation of the *piston* as the means which admits air from the train-pipe to the brake-cylinder presents a claim in which the vice is more difficult of detection, is simply that a *less remote agent* has been designated as the cause.

Starting, then, with the engineer's-valve, the effect of the specified movements in both the compared cases is, *as in all automatic brakes from the beginning*, to deplete, in different degrees, the pressure in the train-pipe. This then is a point of coincidence between the two series of operations, but it presents nothing new in either. The depletion of pressure, in turn, causes the piston to make either a partial traverse, or a complete traverse, according to the degree of the depletion, and it is this greater or less movement of the piston that claim 2 designates as the agent that admits the train-pipe-air to the brake-cylinder.

These three elements or steps in the operation, to wit (1), the movements of the engineer's-valve, (2) the variation of train-pipe pressure, and (3) the movements of the piston, are common to Complainants' patent to Defendants' structure, *and to the prior art*. We have so far found nothing to distinguish Defendants' mechanism from the mechanism of the patent, *and nothing to distinguish the latter from the prior art*. No new element has yet appeared, nor any step in the operation that has a scintilla of novelty. Selecting the engineer's-valve, or the greater or less depletion of air in the train-pipe produced by the movement of the valve, or the consequent partial and further traverse of the piston, or, taking all three together, would equally fail to specify anything novel in construction and operation. *The novel means for actuating the auxiliary-discharge-valve, described in the patent in suit, lie between the piston and the valve.* The novel means invented and patented by Boyden also lie between the piston and the valve that admits air to the valve-chamber, which in his case was not a new valve. Here, *precisely at the point where the novelty begins, the resemblance ceases*, and this is the reason why no possible interpretation of the patent in suit could be adopted which would embrace what Defendants have done.

In the brake of the patent in suit the piston on its further traverse opens the main-valve and also makes contact with a stem 36, displacing the latter against the pressure of a spring, and this displacement actuates the discharge (auxiliary) valve.

In Defendants' brake the further traverse of the piston opens wide the main-valve, as it did in the prior art, and *it does nothing more*. In the subsequent actions the piston is not an actor or agent. An immediate and great difference in pressure is at once established on opposite sides of the old feed-in-valve. Why? Because the passage from the auxiliary-reservoir to the valve-chamber has been *contracted*, so that the valve-chamber empties through the main-valve faster than it can be replenished from the auxiliary-reservoir. Hence the air from the train-pipe enters the valve-chamber just as it did in the Boyden patent of 1883. But up to this point we have no admission of the train-pipe air to the *brake-cylinder*, we have only *discharged the train-pipe*, using the means of the old art to do it. Entering the valve-chamber the air choses the path leading to the brake-cylinder, rather than that to the auxiliary-reservoir, because it finds the old main-valve open, and the path through it is that of least resistance. So it did, and for the same reason, in the Boyden 1883 patent.

In all this there is not the semblance of utilization of a single element in the means for actuating the auxiliary-valve which was new in the patent in suit.

The conclusion must inevitably be that the brake of Defendants' coincides with that of the auxiliary-valve patent in suit in no feature either of construction or operation that was *new with the latter*. It follows, also, as a corollary, that claim 2 is "fatally defective" if interpreted as excluding the means disclosed in the patent for admitting air from the train-pipe to the brake-cylinder.

A TEST FOR INFRINGEMENT.

If Westinghouse took the old triple-valve mechanism and added something to it, thereby accomplishing quick-action, and Boyden took the same old mechanism, added something to it and thereby accomplished quick-action, the resemblance, to constitute infringement, must be found *in the new or added parts*. Now the novelty in the

parts which Westinghouse added did not reside broadly in a passage or in any "device for admitting air from the train-pipe to the brake-cylinder," which was one thing that he added, for he claimed that in original claim 1 and struck it out in view of Boyden's 1883 patent.

He then limited his claim to a device (auxiliary-valve) for admitting air from train-pipe to brake-cylinder *actuated by the further traverse of piston*. This was his novel addition to the old triple-valve mechanism, so far as the patent in suit (and particularly claim 2 thereof) is concerned.

But that did not produce "quick-action," and so he invented further, and added, by a later patent, a better *actuating motor* for his auxiliary-valve device, leaving the latter unchanged. This improved actuating-motor was the "supplemental"-piston of 376,837.

Boyden, by the addition *he* made to the old structure, produced the same result as that produced by the *two* inventions of Westinghouse. This addition consisted in a partition separating the valve-chamber from the piston-chamber, the partition having a small hole or passage through it.

If then each of these persons has accomplished the *same result* (as is granted), the question remains have they done it *by the same means*?

The answer is that the stationary partition of the Boyden brake is not the same means as the by-passage and auxiliary-valve (of one Westinghouse patent), *plus* the supplemental-piston (of the other Westinghouse patent), because it is not the same in structure or in mode of operation. It is radically different in both respects.

If, however, we found as a fact that the means whereby Boyden produces the result of "quick-action" were the equivalents of the means whereby Westinghouse produced that result, nevertheless *infringement could not be found*, because an essential part of the Westinghouse means is *embraced in a patent not involved in this suit*.

THE REAL INVENTION OF No. 360,070 IN SUIT.

This invention has been put forward by Complainants as the *cause* of "quick-action," *i. e.*, as supplying the means whereby the one thing desired ("*coincidence of application*" of all the brakes) was obtained. We have been largely occupied in showing that the

invention has been presented in a false guise, and necessarily have for the most part ignored the real merit of the invention and the real result it attained.

Had Complainants fairly presented their invention to its best advantage without disguise or false pretenses, it would have appeared in this aspect: that the *result* accomplished by the invention had to do solely with the prompt and forceful *individual* application of the brakes, contributing nothing to the quicker *serial* application thereof, and that the improvement or advantage gained lay in securing the individual application of the brakes in emergency stops without employing a larger auxiliary-reservoir, or a larger passage therefrom to the brake-cylinder, than was required for service stops. This advantage was gained by adding the air discharged from the train pipe in making emergency stops, to that from the reservoir, this formerly wasted air contributing one-sixth of the total pressure. This was the *result* of the invention. The means whereby it was attained consisted of the following modifications of what previously existed: (1) connecting the end of the old discharge-passage of No. 217,838 (the local-vent patent) to the brake cylinder, instead of leading it to the atmosphere; (2) connecting the old discharge-valve with the old stem 36 of No. 220,556 (the old automatic triple-valve) so that the movement of the piston would be communicated to this valve through said stem.

The second modification is of little or no importance. Operating the discharge-valve by the further traverse of the piston had *previously* been done in the arrangement described by Mr. H. H. Westinghouse (p. 124). It is not, by anything that appears in the record, the invention of this patentee, and in any event is excluded from the patent sued on. Moreover, it would appear an obvious expedient, on adding another valve to those ordinarily present in the triple-valve, to connect it with the organ whose customary office is to operate all the valves. Invention would hardly be required until it should appear that the piston was not equal to performing this office for the new valve. *Then* it would become necessary to devise a new motor on account of the refusal of the piston to perform the additional labor of operating another valve. This is exactly what happened, the invention of the "supplemental-piston" of No. 376,837, being achieved at enormous cost and by prodigious effort. Until *its* advent

Westinghouse was as far as ever from quick-action. The field was "as wide open" as in 1886.

By the most liberal view of the invention of the patent in suit, we have in these modifications the basis of the broadest possible claims that could be maintained by the patentee. These modifications present no novelty in *structure* in a broad sense, since a passage from the train-pipe to the brake-cylinder, which opened "simultaneously with the opening of the passage from the auxiliary-reservoir to the brake-cylinder,"* is found in Boyden's 1883 patent. Nor does the qualification that this passage is opened simultaneously with the opening of the main-valve *by the piston of the triple-valve*, confer novelty on the means, because the opening of such passage under such conditions and *by such means* is found in the Boyden 1883 patent and is *expressly disclaimed in the patent in suit*. There remains, then, the qualification of doing this at a particular time, or for a particular purpose, *i. e.* at the time when it is desired to produce a quick stoppage of the train. This qualification itself is not patentable, but the *new* means on which it depends are patentable, and thus we finally arrive at the *means* of the patent, to wit, the auxiliary valve and by-passage, when the valve is combined with the triple-valve piston so as to be mechanically actuated thereby, either directly or through a suitable mechanical connection.†

These means are not anticipated by the Boyden 1883 patent, because, while the final movement of the triple-valve piston therein opens a passage from the train-pipe to the brake-cylinder, thus forestalling any broad claim thereon, it does not do this *by acting upon and unseating an auxiliary-valve*.

For the same reason these new means are not found in Defendants' quick-action brake, wherein there is no by-passage and no auxiliary-

* See disclaimer in patent in suit (p. 726, also inserted folder in this brief).

† H. H. Westinghouse, the brake expert for Complainants, understands the patent in this way. He testifies (p. 153):

"182 X-Q. I will state briefly my understanding of the operation of the valve described in each of the three patents. In patent No. 360,070 the valve which controls communication direct between the train-pipe and the cylinder is opened *by means of the triple-valve piston acting mechanically upon it*; in patent No. 376,837 this valve is opened *by auxiliary-reservoir pressure acting independent of the mechanical action of the triple-valve piston*, and in patent No. 393,784 this valve is opened *by train-pipe pressure acting directly on it*. Is this statement correct?"

"A. So far as the operations described are concerned I regard it as substantially correct."

valve actuated by the piston (or by anything else); but wherein the final movement of the piston uncovers the *same* passage from the train-pipe to the brake-cylinder as in the 1883 Boyden patent, and as disclaimed in the patent in suit.

Had the invention of the patent in suit been thus fairly presented on its proper basis, the foregoing facts would have demonstrated that no possible claim could have been drawn and sustained therein which Defendants would have infringed.

The invention of this patent, to wit, efficiency in securing an old effect by a modification of structure which made it unnecessary to provide, for use in making emergency stops, for more ample power or a larger passage from the auxiliary-reservoir to the brake-cylinder than that employed in ordinary service, is, in the presentation of this case, distorted beyond recognition into a new *process* performed by the triple-valve *piston*, "to produce quick-action."

It is to be noted that, while Westinghouse by the invention of the patent sued on, is enabled to employ a main-valve port of the same size for both service and emergency-stops, this being one of the things he gains by that invention, Defendants, on the other hand, open a *wider* passage through the main-valve port when using the brake for emergency-stops, this being the vital feature of the operation of the brake when so employed.

SUMMARY OF THE ARGUMENT.

We feel justified in drawing the following conclusions from what has preceded:

1. That the patent in suit is not the pioneer patent for the "quick-action brake," but that *per contra* it lacked just what the local-vent patent of 1879 lacked to make it a "quick-action" brake, namely—a quick acting motor.

2. That the patent in suit describes no new process, certainly no new process performed by the piston, and therefore cannot be sustained as to process or method.

3. That Defendants' brake, in so far as it accomplishes any result not accomplished by the brake-mechanisms existing prior to the patent in suit, does it by means not disclosed in said patent; and therefore that no valid claim could have

been based on the invention of the patent in suit which Defendants' structure would infringe.

4. That in Defendants' structure the agency of the piston in establishing communication between the train-pipe and the brake-cylinder is identical with the Boyden 1883 patent, and is in express terms disclaimed in the patent sued on.

5. That the Westinghouse brake, as it existed prior to the patent in suit, lacked one essential thing to give it the characteristic of quick-action, which essential or "indispensable" thing (a quick-action motor) the invention of that patent did not supply, and which is covered by a later patent not involved in this suit.

This brings us to the conclusion of the inquiry which we undertook to conduct. There remain several topics which come properly within the scope of that inquiry, discussion of which we have reserved to this point to avoid interruption of the direct thread of the argument.

MORLEY MACHINE COMPANY VS. LANCASTER,

(129 U. S., PAGE 263.)

Should the Court pass on the question of "pioneership," that question will undoubtedly be examined in connection with this leading case. Therefore a brief reference to the rule as therein stated and applied will be appropriate.

The Court held that Morley was a "pioneer" inventor because he was "the first inventor of an *automatic button-sewing machine*;" that is to say the patent involved *in that suit* disclosed the first machine which successfully did that work.

Having found that to be a *fact*, and that the successful machine comprised as its *essential* elements three sets of mechanisms, to wit, spacing mechanism, feeding mechanism, and sewing mechanism, the Court proceeded to construe the patent as broadly for a *combination* of those three sets of essential mechanisms, the omission of any one of which would have prevented the accomplishment of the result of the invention.

Infringement, under the rule of that case, depended upon finding in the Defendant's machine, not the *result* of the combination, but the *equivalent of each of these essential mechanisms, combined so as to produce that result.*

In the case at bar, granting that Westinghouse was the first inventor of a "quick-action brake," the two things which are "*both essential to the structure of the successful quick-action brake,*" according to the last judgment of the New York Court (quoted with approval by Complainants herein) are (1) the auxiliary-valve of the patent in suit, (2) the "supplemental piston or special motor" of the later patent, No. 376,837. The latter, according to this decision, is *a part that cannot be dispensed with*, and Complainants' counsel quote that finding and insist on its correctness.

Therefore, to apply the rule in *Morley vs. Lancaster*, it is necessary to find in Defendants' structure "the proper equivalent" for this "*indispensable part.*" That decision, after citing and explaining the pertinent decisions of this Court and of English Courts, proceeds to apply the rule deduced therefrom (p. 283):

"Applying these views to the case in hand, Morley having
 "been the *first inventor of an automatic button-sewing machine,**
 "by uniting in one organization mechanism for feeding buttons from a mass, and delivering them one by one to sewing-mechanism, and to the fabric to which they are to be secured, and sewing-mechanism for passing a thread through the eye of the button and securing it to the fabric, and feeding-mechanism for moving the fabric the required distances to space the buttons, another machine is an infringement, in which *such three sets* of mechanism are combined, *provided each mechanism, individually considered, is a proper equivalent for the corresponding mechanism in the Morley patent*; and it makes no difference that in the infringing machine, the button-feeding mechanism is more simple, and the sewing-mechanism, and the mechanism for feeding the fabric are different in mechanical construction, *so long as they perform EACH the same functions as the corresponding*

* By the invention of the patent sued on.

"mechanism in the Morley machine, in substantially the same way, and are combined to produce the same result."

And again—

"In all three of the main mechanisms used in the the Lancaster machine, the means employed in it are substantially equivalents of those employed in the Morley machine."

If, then, we attempt to apply this decision, arguing from the premise that Defendants' accomplish, in their brake, the same result which Westinghouse was the first to accomplish, we must find in the former the proper equivalent for *each* of the essential elements (*indispensable parts*) of the successful Westinghouse brake, performing *"each the same function as the corresponding mechanism in the Westinghouse machine."*

On examination we find in Defendants' brake no proper equivalent for the auxiliary-valve, (for the mechanism contains only the usual valves of the old triple-valve,) operating in substantially the same way; nor any equivalent for the other essential mechanism, the supplemental-piston. The inevitable conclusion is that Boyden has produced the result of "quick-action" by means substantially different. Those means consist of a *contraction* in the passage leading from the auxiliary-reservoir to the valve-chamber.

If, however, we had found that the perforated partition of Defendants' brake *is* the proper equivalent of the auxiliary-valve and of the supplemental-piston, nevertheless infringement could not be found under the rule of Morley vs. Lancaster, because one of these *essential elements* of the Westinghouse machine, which actually produced quick action, is covered by a patent *not involved in this suit*.

RISDON LOCOMOTIVE WORKS VS. MEDART,
(158 U. S. PAGE 68).

If Claim 2 of the patent sued on could be interpreted as for a process of admitting air from the train-pipe to the brake-cylinder by a certain movement of the piston, the question would arise whether, under the settled law of this Court, this operation constitutes a patentable process, as distinguished from the mere functions of mechanical elements.

Such an operation as discharging air, steam, or other agent, may manifestly be a process, as for instance where the agent acts upon a substance "to be transformed and reduced to a different state or thing" (Cochran vs. Deener, 94 U. S. 780). In the process of purifying middlings a current of air was one of the means which (with screening, grinding and rebolting) effected the object of the invention.

Another illustration is furnished by the sand-blast case (Hartell vs. Tillghman, 99 U. S. 547) where a blast of sand impinging upon glass, metal, etc., transformed it to a different state.

Whether the use of compressed air in a machine to exert pressure on a brake could, in any state of the art, be regarded as a process is extremely doubtful. In the air-brake the air acts simply as a mechanical element analogous to a lever, screw, belt or any other mechanical element, to convey power from the air-compressor to the point of application. Compressed air in the air-brake has simply the function of a spring, and in many arts is a well-known substitute for metal springs. But this question requires no discussion, since the process, if any, was old at the date of the patent. Compressed air had been admitted from the train-pipe to the brake-cylinder to perform its usual office there, and this had been done simultaneously with the admission of air thereto from the auxiliary-reservoir. Of novelty, therefore, there remains only the performance of these old operations *by certain specific agents combined in certain specific relations*, to wit, by a valve (governing a passage leading to the desired point) connected with and actuated by the triple-valve piston. The novelty, therefore, resides wholly in a specific arrangement of machine elements, each performing its customary function, and together performing an operation which was old.

The distinction between a patentable process and a function of mechanism, though not always easy to draw, has been recognized from the earliest times.

The famous patent of James Watt, the father of the modern condensing steam engine, provoked a learned discussion on this point in 1795 from the Court of Common Pleas and the King's Bench in *Boulton vs. Bull* (2 H. Bl. 463) and *Horblower vs. Boulton* (8 F. R. 95). The patent specified the invention as a "method" whereof a salient feature consisted in "condensing the steam outside the working cylinders." The construction adopted to save the patent interpreted the inven-

tion as for the *combination* of the cylinders with external condensers. That there was no process or method involved was clearly elucidated by the opinions of the learned judges who were called upon to construe the patent. (See also the great English case, *Nelson vs. Harford*, 1 Webster's patent case.)

The distinction was first clearly drawn by this Court in *Corning vs. Burden* (*supra*), where the patent sued on claimed a process which consisted in treating masses of molten iron between a revolving cylinder and a curved trough, or equivalent devices. In defining a process the Court said :

"It is for the discovery or invention of some practical
 "method or means of producing a beneficial result, or effect,
 "that a patent is granted, and *not for the result or effect itself.*
 "It is when the term process is used to *represent* the means
 "or methods of producing a result that it is patentable, and
 "it will include all methods or means *which are not effected by*
 "*mechanism or mechanical combination.*"

It will not be necessary to follow this doctrine through the cases in which it has been stated and applied in this Court, for the reason that in the recent decision in *Risdon Works vs. Medart* the Court, after quoting at length the definition given by Mr. Justice Grier in *Corning vs. Burden*, said :

"Although the cases are not numerous this distinction
 "*between a process and a function has never been departed from*
 "*by this Court.*"

The decision in the *Medart* case has by some courts and lawyers been regarded as drawing a distinction (not "between a process and a function") but between a process which is of a physical or chemical character, and a process that is of a mechanical character.

To those who observe the recent teachings of science it is not possible to perceive any philosophical distinction between these different manifestations of energy. Science points ever more and more steadily to a common origin for all forms and manifestations of energy. Whether for convenience we speak of a particular manifestation of force as vital, or chemical, or electrical, or mechanical, we recognize that these are, one and all, manifestations, in different aspects, of the same Force which pervades the universe. The patent law must observe the facts of the universe and can create no distinc-

tion where none exists. It is not necessary, for the purpose of reaching the conclusion we have in view, to strain in the least the doctrine of the Medart case beyond what appears to us to be its clear import. It affirms and emphasizes all the previous decisions of this Court wherein the same question has arisen, establishing firmly that if the invention is a *machine* the patent cannot be sustained as for a *process*, even though the invention be claimed as such.

A fortiori, if the invention be a machine, and be described and claimed as such, the patent cannot be sustained "as to process or method."

ANALYSIS OF PATENT IN SUIT.

(SEE ANNEXED FOLDER.)

In order to lighten the labor of the Court and to make conspicuous the features alleged in the patent specification to be novel; and to show that no reference is made therein to a process or method, but that *per contra* its terms preclude such interpretation, the entire specification has been printed and arranged in three colors in the annexed folder. All the paragraphs and parts thereof in the specification and claims which pertain to *what is new* are colored red, those pertaining to the old prior brake art are black, and that pertaining to the prior art of 1883 is green. A perusal of the specification as far as printed in black will disclose the principal members and operations of the "old automatic brake," upon which the new invention is an improvement. It is sufficient to state that the "old automatic brake" consists of a *main-air pipe*, a *brake-cylinder*, an *auxiliary-reservoir*, and a *triple-valve*, the latter having a piston which has, and had prior to the invention in suit, *two traverses*, one the *preliminary* which was used to operate valves to apply the brake for service stops, and the other, the *further traverse* to operate another valve for emergency stops.

The first red paragraph (A) distinctly states that the invention consists of "*Improvements in Fluid Pressure Brake Mechanism*," not in a *method* or *process*.

The second red paragraph (B) sets forth the object of the invention—rapidity, effectiveness and economy being the *desiderata*. In

this paragraph no method, process or device is described for accomplishing the objects stated.

The third red paragraph (C) refers to an alleged "novel combination of four elements, namely, a brake-pipe; an auxiliary-reservoir; brake-cylinder; and a triple-valve device—all of which are acknowledged later on in the specification (in black) to be old in the art. The "triple-valve" device, however, is characterized as "*governing communications*," not providing the means of communication. Therefore the duty which the "triple-valve" device is to perform in the invention to be disclosed is not doing the work, but in "*governing*" the communications that *are* to do the work. "The improvements *claimed* are hereinafter fully set forth," *i. e.*, the improvements by which the *objects* stated in the preceding paragraph (B), and restated in the following fourth paragraph (D), are accomplished.

The fifth red passage (E) is part of a paragraph in which the patentee refers in general terms (afterwards stated specifically) to the old and new parts of the mechanism. The subject of this paragraph is "the triple-valve 10," which numeral designates on the drawings the entire triple-valve structure including both *old* and *new* parts. It is here stated that this "triple-valve 10" accords substantially with prior patents, and "is not claimed as of my present invention," except as to certain "structural features, by which it performs the further function of effecting the direct admission of air from the main air-pipe to the brake-cylinder." (The word "function" is employed here and elsewhere in this specification as if synonymous with "operation" or "effect.")

Before pointing out specifically what these new "structural features" are, the patentee proceeds to describe at length the *old* parts of the mechanism and their mode of operation. This occupies the the next five paragraphs of the specification, interrupted only by the brief red passage (F). This passage refers only to the minor detail of the small port 35 in the main-valve.

These five paragraphs, printed in black, embrace the description of the *piston*, with its shorter and longer movements (the terms "preliminary" and "further traverses," not being used in the specification), including the action of the piston in displacing, in its final movement, the stem 36. So far from there being a hint of any novelty in the

structure or operation of the piston, this long description of the old parts and their operation concludes with the statement :

"So far as hereinbefore described, the triple-valve accords
"in all substantial particulars with, and is adapted to operate
 "similarly to, those of my letters-patent Nos. 168,359,
 " 172,064, and 220,556."

This passage sharply draws the line in the description between the old parts of the triple-valve 10 and the new or additional parts, which are described in detail in the seventh red passage (G). These new parts, which enable the triple-valve "to perform the further functions requisite in the practice of my present invention" are specified as "certain additional members," to wit, the "auxiliary-valve 41" and the "passage 46."

It is particularly to be noted that, in this detailed description of the construction and operation of the *new* parts there is *no reference at all to the piston*. The auxiliary-valve 41 is described as "connected to" and moving with "the stem 36." There is not the faintest suggestion that the patentee has invented either a new process, or a new piston, or a new operation performed by the piston.

The eighth red passage (H) describes the operation of the additional members (*valve* and *by-passage*) upon a sudden and great reduction of train-pipe pressure, "when the piston of the triple-valve is forced to the extreme limit of its stroke," "carrying with it the stem 36." This describes not a new, but the old operation of the piston, the only novel operation being that of the valve.

The ninth red passage (I) refers further to the action of these additional members. It points out that the discharge of air from train-pipe to brake-cylinder is effected *by the auxiliary-valve and by-passage*—not by the piston—and that the supplemental port 35 of the *main-valve* is opened "*when* the piston 12 arrives at the extremity of its stroke."

The disclaimer, in green, effectually disclaims the Boyden brake of 1883, and also Defendants' quick-action brake, particularly *that office of the piston of the latter which is now pointed to as constituting identity of Defendants' brake with the alleged subject-matter of claim 2*, because the piston in Defendants' brake does nothing more than or different from that which is disclaimed.

In Claims 1 and 4 the new parts, in red, give patentability to the claims. Claim 2 is printed entirely in black, because the combination specified is in its entirety old (and so declared to be in the specification), the only new thing asserted being something alleged to be *done* by the piston, which allegation the entire preceding description contradicts.

From the foregoing we may deduce with great certainty the conclusions :

1. That the invention described pertains to "improvements" in "mechanism" (passage A).
2. That it consists in certain "*structural* features" added to the old parts of the triple-valve, and that save as to these *structural* features nothing in the construction or operation of the triple-valve is "claimed as of the (my) present invention" (passage E).
3. That in structure, function, and mode of operation, the piston is old, and accords with previous patents.
4. That the "structural features," or "additional members" which enable the organization *as a whole* to effect "the direct admission of air from the main air-pipe to the brake-cylinder" are the "auxiliary-valve 41" and "passage 46," (passage G).
5. That the effect, erroneously attributed in claim 2 to the piston, is that of an *organization* composed of many elements, whereof the salient and new elements (auxiliary-valve and by-passage) are not recited in the claim.
6. That no paragraph, sentence or word hints at any new process or method; but, *per contra*, the patentee explicitly says that he claims only certain "*structural* features."

The foregoing conclusions are confirmed by the Patent Office file contents, by the prior art, and the history of the development of the Westinghouse brake, as fully shown in previous parts of the brief.

Respectfully submitted,

LYSANDER HILL,
HECTOR T. FENTON,
MELVILLE CHURCH,
ANTHONY POLLOK,
PHILIP MAURO,

March 7, 1898.

Of Counsel for Defendants.

Addendum in Reply to Brief for Complainants.

The brief filed for Complainants on this third argument invites criticism on every page ; but the only matter which we deem worthy of any reply is the attempt made on page 28 to formulate a construction of Claim 2, which the Court is asked to adopt as the proper interpretation of that claim.

The claim as thus formulated modifies the language of the claim as found in the patent by inserting the words "*by opening a port*" after the words "preliminary traverse," and again after the words "further traverse." We have now another element brought into the claim, to wit, a "port," or, rather, "two ports," and are afforded thereby a clear recognition on the part of Complainants' counsel of the existence of what we have herein referred to (see p. 35) as the vice in Claim 2. They recognize that the claim is defective in not specifying the means which produce the effect, but reciting instead a device which merely conveys power to those means ; and they here attempt to obscure this defect by introducing an element (port) which may produce an appearance of conformity to the statute without sacrificing that indistinctness which alone makes the claim valuable to Complainants. If the Court recognizes the principle to which we have called attention they will have no difficulty in seeing that its application requires the presence in the claim of an auxiliary-valve and by-passage, or the equivalents thereof. The "port" does not produce the described effect any more than does the piston ; nor does the piston open a port.

But there is no justification for this formula ; on the contrary all the pertinent facts preclude its adoption. The specification does not ascribe the specified effect to a "port," but to an additional valve and by-passage. Every claim of the patent, including Claim 2, as interpreted to the Patent Office by the attorney who drew it, specifies these elements as the means which produce the described effect.

The charge of infringement which defendants were called upon to meet was based on the alleged use of an "auxiliary-valve" (additional to the usual valves of the brake-mechanism), controlling a passage from the train-pipe to the brake-cylinder. That charge has been met, and has been disposed of by both the lower courts. It falls when the conclusion is reached that valve 22 of Defendants' brake is not Complainants' "auxiliary" valve. The effort now is to find an interpretation of Claim 2 that will ignore its character as a combination claim and embrace means substantially different from those which the patent discloses for producing the described effect. This is not possible unless it can be construed and sustained as for a process, which our opponents concede cannot be done.

On the other hand we submit that Claim 2 can be sustained only by construing it as for a combination including with its recited elements (not a "port") but an auxiliary-valve and conduit controlled thereby and leading from the train-pipe to the brake-cylinder.

This interpretation is that of the solicitor who prepared it, is that upon which the Patent Office granted it, is that of the specification, and is supported by Complainants' *prima facie* proofs.

Can Claim 2 be Construed as for a Process?

This question involves two inquiries, viz: (1.) Even if the thing described in the specification involved a patentable process, can *this patent* be construed to cover it? and, (2.) Does the invention involve a patentable process?

We will consider these two subjects in their order :

I.

Does the Patent Describe or Claim a Process ?

The claim is in terms, for a mechanical combination. To construe such a claim as for a method or process is to do violence to its language. The settled rule of law is that the words of a patent, like those of any other contract, must be construed in their plain, ordinary, and usual signification ; and this rule will be clearly disregarded if this claim be construed as for a process or method.

This rule is never disregarded unless there exists some paramount necessity for so doing. The necessity exists only when it is clear that the words, if taken in their plain, ordinary, and usual signification, will fail to express the meaning intended by the parties. The intended meaning must be shown by the document itself, or, in case of a latent ambiguity, must be proved by other evidence ; in no case can it be derived merely from guess-work on the part of the Court.

The question then arises whether Westinghouse *intended* to take out a patent for a method or process instead of one for a mechanical combination, and whether the Government understood him as applying for a process or method patent and intended to grant him such a patent.

The patent and the application proceedings clearly negative any such theory, because the language found therein, both of himself and of his patent solicitor, Mr. J. Snowden Bell, is in irreconcilable conflict with any such theory. *That language could not have been used, and it never would have*

entered their minds to use it if they had had the idea that they were taking out a method or process patent.

(a) It is inconceivable that if they were intending to procure a method or process patent they could have drafted and filed a specification of more than five hundred and fifty printed lines in length without once even mentioning the word "method" or "process," or hinting that this was what they were trying to protect.

(b.) Mr. Bell, who drew the specification and claims, was an experienced and competent patent lawyer and solicitor—so competent that, in this suit, he was entrusted with the responsible duty of taking all the testimony on behalf of the complainants and of cross-examining the defendants' witnesses. He knew, as well as he knew his own name, that in all the great process cases—the chilled car-wheel, the Goodyear rubber, the driven-well, the torpedoing of oil-wells, the sand-blast, the fat-acid, the beer fermentation, the nickel-plating, the telephone, the Cochrane flour purifier, and other similar cases—the claim which was sustained for a process or method was, in express terms, *a claim for a process or method*, and that there is not a case on record where a claim, in terms for a mechanical combination, had been construed as for a process or method. If he had desired to secure a claim for a process or method and other claims for mechanical combinations, the Bell Telephone case taught him that the proper form of claim was: "The method of and apparatus for" accomplishing the desired result. It is simply inconceivable that such a lawyer could, while intending to patent a process or method, have drawn and filed a specification and claims which do not even hint at such an intention.

(c.) Mr. Westinghouse was not an ignorant "backwoodsman," unfamiliar with the meaning of terms used in mechanics and in patents, but an intelligent and able man,

of great experience in these matters, to the study of which his whole life had been largely devoted. His success in business shows that he is also a man accustomed to look closely after his own interests and to claim the full benefit of his legal rights. He knew the practical difference between a "process" or "method" and a "mechanism" or a mechanical "combination," as well perhaps as it is known to any member of this court.

(d.) It is absolutely inconceivable that, with the intention of patenting a method or process, either Mr. Bell or Mr. Westinghouse would have prepared and filed a specification which begins with these words: "Be it known that I, George Westinghouse, Jr., residing at Pittsburg, in the county of Alleghany and State of Pennsylvania, a citizen of the United States, have invented or discovered certain new and useful improvements in Fluid-Pressure Automatic Brake *Mechanism*, of which improvements the following is a specification." Here, there was sharply presented to their minds the very question of what the invention consisted in, and what they were going to describe and cover in their specification and claims; and they decided that it was not a method or process, but an improvement in the mechanism.

(e.) A few lines further on the same question was again sharply presented to their minds, and, at lines 20-27 of the specification, they declared that the invention "*consists in a novel combination*" of certain mechanical elements which they proceed to mention.

How is it *possible* that they could have made these declarations if they had understood that the invention consists in a new process or method and not in a new mechanical combination or mechanism?

(f.) Again, in claim 2, Mr. Westinghouse says, with the evident approval of Mr. Bell: "I claim as my invention and desire to secure by Letters Patent. * * * *In a brake*

mechanism, the *combination* of a main air-pipe, an auxiliary reservoir, a brake cylinder and a triple-valve," etc. Here, the claim is expressly limited, first, to a "mechanism," and secondly to a specific "combination" contained in that mechanism.

(g.) Finally as if to clinch the matter and leave nothing for future controversy, Mr. Westinghouse, in lines 41-46 of page 2 of his specification, expressly declared that he *did not claim* the triple-valve, "saving as to the *structural features by which it performs* the further function of effecting the direct admission of air from the main air-pipe to the brake-cylinder, as presently to be described."

It is seen, therefore, that the patent contains four emphatic declarations on the very point here in question, all concurring that the invention is an improvement in the mechanism, and not a word to show that either Mr. Westinghouse or his solicitor had the slightest idea that they were going to patent a method or process.

(h.) Two months after filing said specification, Mr. Bell, (January 19, 1887,) in his letter to the Commissioner of Patents again declared their intention to patent, not a process or method, but a mechanism, saying that "*When, however, the triple-valve is provided with an auxiliary-valve operated by its piston, which performs a new function additional to that of the triple-valve as previously employed, it is believed that such combination is wholly novel.*"

(i.) Moreover, throughout the entire specification, whenever Mr. Westinghouse or his solicitor had occasion to speak of the new work which the new mechanism performs, they do not refer to it as in the nature of a new method or process, but expressly as merely *a function of the new mechanism*. Thus, at page 2, lines 42 and 43, the patentee calls it "the further *function* of effecting the direct

admission of air from the main air-pipe to the brake-cylinder," and, at page 3, lines 44 and 45, he calls it "the further *functions* requisite in the practice of my present invention," while Mr. Bell, in his letter to the Commissioner, also calls it "a new *function* additional to that of the triple-valve as previously employed." The new work accomplished by the new mechanism addressed itself to their minds, not as a new method or process, but merely as a function of the mechanism described. If there was a new method or process involved, they evidently did not know it. To their minds, everything connected with the invention was mechanism, and its work was the mere function of mechanism. Nor is there any evidence that the Patent Office officials took any view of the matter different from that of Mr. Westinghouse and his solicitor. On the contrary, the fact that the Examiner refused to allow claim 2 until after Mr. Bell had, by his letter of January 19, 1887, declared that he was not seeking a broad claim, but only a claim for a specific combination containing the auxiliary valve as an element, shows clearly that the Examiner had no intention of granting a process claim.

Therefore, to construe claim 2 as for a method or process would be to do violence to its plain language, *not for the purpose of promoting, but of defeating*, the clearly expressed intention of the parties to the contract. Such a decision would overthrow the precedents, of a century and reduce the law relating to the construction of contracts and other documents to a state of absolute confusion.

Moreover, this court has repeatedly held, in the reissue cases arising since *Miller vs. The Bridgeport Brass Co.*, 104 U. S., 350 that in construing the claim of a patent the patentee is bound by his original intention to take a restricted claim,

and is estopped from subsequently attempting to enlarge such a claim. He can be relieved only in cases where there was some inadvertent error in the description, or where he intended to make a broad claim and by inadvertence, accident or mistake made a narrow one—and this, clearly, for the purpose of effecting, not of defeating, his original intention.

The fact that the clear language of a claim renders it narrower than the invention actually made by the patentee does not authorize the courts to construe its words other wise than in their plain, ordinary and usual signification.

“Where a claim is so explicit the courts cannot alter or enlarge it. * * * But the courts have not the right to enlarge a patent beyond the scope of its claim as allowed by the Patent Office, or the appellate tribunal to which contested applications are referred. When the terms of a claim in a patent are clear and distinct (as they always should be,) the patentee, in a suit brought upon the patent, is bound by it. (*Merrill vs. Youmans*, 94 U. S., 568.) He can claim nothing beyond it. * * * As patents are procured *ex parte*, the public is not bound by them, but the patentees are. And the latter cannot show that their invention is broader than the terms of their claim, or, if broader, they must be held to have surrendered the surplus to the public.”

Keystone Bridge Co. v. Phoenix Iron Co., 95
U. S., 274, 278-9.

Again, the proposed construction would make for Mr. Westinghouse a new patent, for a different invention; for this Court has repeatedly held that a process and a machine are not the same invention, and that for this reason, if no

other, a patent for a machine cannot be reissued for a process. (*Eachus vs. Broomall*, 115 U. S., 429; *Heald vs. Rice*, 104 U. S., 737, 753; *James vs. Campbell*, 104 U. S., 356, 376-7; *Wing vs. Anthony*, 106 U. S., 142).

Among the decisions of this Court, several cases are reported in which a claim, in terms for mechanism, was sought to be construed as a claim for a method or process; but in every instance the Court held the contrary. In some of these cases the patentee's right to cover a method or process was much clearer than in the case at bar. For example, in *Leroy vs. Tatham*, 14 How., 156, there was no doubt that the Hansons had discovered a property of metallic lead before unknown; and their invention utilized this property for an important industrial purpose. But their claim was for "the combination of the following parts above described, to wit, the core and bridge or guide-piece, the chamber, and the die, when used to form pipes of metal, under heat and pressure, in the manner set forth, or in any other manner substantially the same." The Court, speaking through Mr. Justice McLean, said :

"The patentees have founded their claim on this specification, and they can neither modify nor abandon it in whole or in part. The combination of the machinery is claimed, through which the new property of lead was developed, as a part of the process in the structure of the pipes. But the jury were instructed, 'that the originality of the invention did not consist in the novelty of the machinery, but in bringing a newly discovered principle into practical application.' The patentees claimed the combination of the machinery as their invention in part, and no such claim can be sustained without establishing its novelty— not as to the parts of which it is composed, but

as to the combination: *The question, whether the newly developed property of lead, used in the formation of pipes, might have been patented, if claimed as developed, without the invention of machinery, was not in the case. * * **

"We think there was error in the above instructions, that the novelty of the combination of the machinery, specifically claimed by the patentees as their invention, was not a material fact for the jury, and that on that ground the judgement must be reversed."

In *Crescent Brewing Co. vs. Gottfried*, 128 U. S. 158, 166, the claim was for "The application of heated air under blast to the interior of casks by means substantially as described, and for the purposes set forth;" and the court said that the claim "is a claim to the means or apparatus described for applying the heated air under blast to the interior of the casks, and is a claim for mechanism and not for a process."

In *Grier vs. Wilt*, 120 U. S. 412, 428, the claim was, in terms for mechanism. The complainant contended (see pages 425, 426): "That the patentee is the originator *"of an idea*, which is a novel and useful one, of raising the stack of trays from a point on the lowermost tray of the stack, thus making an opening for the insertion of a fresh tray containing fruit, and in this manner building the stack up from the bottom instead of from the top; * * * the object and value of the patent consisting not in the use of any special machinery for elevating the stack for the purpose intended, but the elevation and opening of the said stack at the bottom, for those purposes, by any machinery best calculated to attain that end." The Circuit Court adopted this view; but the Supreme Court held the contrary and reversed the decision below, saying (page 428) "*This is the effect or result of the mode of operation of the devices. The claim, however, is not for a process, but is only for mechanism.*"

In *Weatherhead vs. Coupe*, 147 U. S. 322, 333, the first claim was for mechanism, and the third claim for a method, but this court held that the method consisted, in substance, in using the mechanism specified in the first claim, and therefore could not be infringed otherwise than by infringing the first claim—in other words, that the third claim, notwithstanding its form, was substantially a claim for mechanism. The Court did not advert to the question whether the third claim was void for claiming merely the function of the mechanism specified in the first claim, but contended itself with saying, in substance, that as the defendant did not use the same mechanism, he did not infringe the patent.

In *Dreyfoos vs. Wiese*, 124 U. S., 32, 36, the claim was for mechanism, the operation of which was to impart a circular direction to the feed-motion by feeding faster at one end than at the other. It was contended for the plaintiff that as Beck was the first to devise a combination, the gist of which was to feed faster at one end than at the other, he was entitled to cover all variations in the form of the feed, so long as by any means it operates in this way; and that if that result is accomplished, the mechanism must be an equivalent for that of the plaintiff.

Both the Court below and this Court held that the patent *must be limited to the mechanism described and claimed*, and could not be extended so as to cover all mechanism for giving a circular direction to the feed-motion, nor to the process of operation of the mechanism described in the patent; and that the defendant, who used a different mechanical means for getting the same result, did not infringe.

In *Yale Lock Co. vs. Sargent*, 117 U. S., 373 (cited in the case last mentioned), the object of the invention was to obtain the variable action of two rollers with respect to the cam by which they were operated. The patentee, who

seems to have been the first in the art to utilize this principle, accomplished the result by using rollers of different eccentricity, and claimed rollers of varying eccentricity when combined with the cam. The defendant used rollers of equal eccentricity, and varied their action with respect to the cam by other means. It was contended that the patentee was entitled to cover the new and useful result which his mechanism produced; but this Court, reversing the decision below, held the contrary.

In *Burt vs. Evory*, 133 U. S., 349, the specification stated that the invention consisted in a *mode of constructing* a shoe, but ended by claiming a *shoe* having certain peculiarities of construction. The Court held that the patent was for a shoe, and not for a method; and laid stress upon the fact that the patentee's counsel, in his brief, had admitted such to be the fact.

Many other cases may be cited to the same effect, and, so far as we know, none to the contrary. The general principle of them all is, that no matter what may be the invention of the patentee, if he has limited his claim to a mechanism it must be construed as for a mechanism and cannot be enlarged to include a process or method.

II.

Does the Invention Involve a Patentable Process?

This brings us to the question: What is a patentable process?

A process may be patentable irrespective of the particular form of the instrumentalities used, (*Cochrane vs. Deener*, 94 U. S., 780, 787; *The Telephone Cases*, 126 U. S., 533); but where mechanism of a certain character is necessarily

used in carrying out the process, the process may be construed as involving such mechanism. (Lawther vs. Hamilton, 124 U. S., 1; LeRoy vs. Tatham, *supra*; Tilghman vs. Procter, 102 U. S., 707.)

"A process is a mode of treatment of certain materials to produce a given result. It is an act, or a series of acts, performed upon the subject-matter to be transformed and reduced to a different state or thing. If new and useful, it is just as patentable as is a piece of machinery. In the language of the patent law, it is an art. The machinery pointed out as suitable to perform the process may or may not be new or patentable; whilst the process itself may be altogether new, and produce an entirely new result. The process requires that certain things should be done with certain substances, and in a certain order; but the tools to be used in doing this may be of secondary consequence." (Cochrane vs. Deener, 94 U. S., 780, 788.) "It may be said, in general, that processes of manufacture which involve chemical or other similar elemental action are patentable, though mechanism may be necessary in the application or carrying out of such process, while those which consist only in the operation of a machine are not." (Risdon Locomotive Works vs. Medart, 158 U. S., 68, 72.) A process may include the entire series of steps employed in the production of a certain article, or it may, as in Fermentation Co. vs. Maus, 122 U. S., 413, involve but a single step in the series. If it consists merely in a series of manual or mechanical operations, involving only the skill or judgment of the experienced workman, it lacks invention, and for that reason is not patentable. And if, in these manual or mechanical operations, the workman uses improved tools or machinery, the protection, if obtained at all, must be obtained through patents on the new or improved tools or machinery. (Risdon Locomotive Works vs. Medart, *supra*.)

Where a process being new and involving a discovery, or the exercise of invention produces a useful *product*, new or old, or an improvement in a useful product, there is no doubt as to its patentability under our laws. In England it was for a long time held that in such cases the invention consisted in the product as a vendible commodity, and that the process of manufacture was not patentable; but for the past fifty years it has been held there as here, that, in such cases, the process of manufacture itself is patentable. Such a process is, in substance, an improvement in the *art of manufacturing* the useful product. In such sense the telephone process was an improvement on the art of producing, at a distance, a copy or copies of the words or sounds uttered in the neighborhood of the transmitting instrument; the driven-well process was an improvement in the art of constructing wells; the Cochrane purifier process was an improvement in the art of manufacturing flour; the Tilghman process, an improvement in the art of manufacturing fat acids; the Hanson process, an improvement in the art of manufacturing lead-pipe; the Neilson process, an improvement in the art of manufacturing iron; the Meller & Hoffman process, an improvement in the art of manufacturing beer, &c., &c. This court, in *Risdon Locomotive Works vs. Medart*, (158 U. S. 68, 77), said of these processes: "It will be observed that, in all these cases, the process was either a chemical one, or consisted in the use of one of the agencies of nature for a practical purpose." The Court might have said, with equal force, that in all of them the process was concerned in the production of some useful article or thing, either in the nature of a vendible commodity, or, as in the telephone production of sound-copies at a distance, something closely akin thereto—there was something which, in the language of *Cochrane vs. Deener*, was to be transformed and reduced to a different state or thing, by an act or a

series of acts. Even a preserving process may justly be regarded as but the last step of a series whose object is to produce the food of other article in a condition suitable for transportation or subsequent use. It is doubtful whether, under the laws of England or America, a process is patentable unless it is concerned in the production of a substantial product. In not a single case that we can call to mind has the Court ever sustained a process patent for an improvement in a *mechanism*, whereby merely its quickness of operation or power of action was promoted-improvements of this character having always been left to the protection afforded by mechanical patents. It would be a radical innovation, leading, no man knows whither, if the field of process patents were now enlarged to include these mere mechanical results.

The Courts have never given a terse and exact definition of a patentable process. Perhaps it cannot be done. In the *Medart* case, this Court, speaking through Mr. Justice Brown, said: "That certain processes of manufacture are patentable is as clear as that certain others are not, but nowhere is the distinction between them accurately defined. There is somewhat of the same obscurity in the line of demarkation as in that between mechanical skill and invention or in that between a new article of manufacture, which is universally held to be patentable, and the function of a machine, which it is equally clear is not. It may be said in general that processes of manufacture which involve chemical or other similar elemental action are patentable, though mechanism may be necessary in the application or carrying out of such process, *while those which consist solely in the operation of a machine are not*. By "elemental action" we understand the Court here to mean to exclude the mere mechanical action of the elements. With this understanding, perhaps a definition can be approxi-

mated by combining together the statements of the Medart, Cochrane and Burden cases, substantially as follows, viz.:

"A patentable process is a process of manufacture consisting in an act or series of acts involving chemical or other similar elemental action, by which a substance or article is transformed and reduced to a different state or thing."

Whether this definition be satisfactory or not it is certain, as above stated, that neither in England nor America have the courts ever sustained a process patent for an improvement in mechanism, whereby merely its quickness of operation or power of action was promoted. In all such cases the increase of quickness or power is a *mechanical result*, necessarily due to some physical change in the organization of the machine; and the *invention* consists in the devising of the change of organization which causes the new or improved result. The change of physical organization has brought into existence a new mechanical combination, or possibly a group of them. This new combination acts differently from the old, *because* it contains some mechanical element absent from the old, or some new arrangement or adjustment of the old elements, producing either a new kind of co-action among the several elements composing the combination or else an additional action not produced by the combination before. At all events there is a *new action*; and, in *Blake vs. San Francisco*, 113 U. S., 679, 688, this Court held that it must be new *in kind*, in order to confer patentability. The peculiar new action, in the combination, of the new element, adjustment or arrangement, is, of course, necessarily caused by a new mode of operation of the combined elements, and it is this new mode of operation that enables the desired result to be effected.

In *Winans vs. Denmead*, 15 How. 330, 341, this Court held that "the patentee may, and should, so frame his specification of claim as to cover this new mode of operation which

he has invented ;” but in the later case of *Burr vs. Duryee*, 1 Wall., 531, the same Court said (page 570) that the patent law gives “*no authority to grant a patent for a ‘principle’ or a ‘mode of operation,’ or an idea, or any other abstraction ;*” that (page 571 :) “All others have an equal right to make improved machines, provided they do not embody the same, or substantially the same *devices, or combination of devices*, which constitute the peculiar characteristic of the previous invention;” that (page 572) the argument : “That two machines produce the same effect will not justify the assertion that they are substantially the same, or that the devices used by one are, therefore, mere equivalents for those of the other;” and (page 573) that “*This is a flagrant abuse of the term ‘equivalent.’*”

From these two cases, taken together, it follows conclusively that he who would cover a new “principle” or “mode of operation” in a machine, must first ascertain what new mechanical peculiarity of the machine in question it is that is necessary to the new mode of operation, and must claim such new mechanical peculiarity—in other words, he must claim the new device or mechanical means which produces the new mode of operation.

It was in this sense that the Supreme Court said in *O’Reilly vs. Morse*, 15 How. 62, 119 :

“Whoever discovers that a certain useful result will be produced in any art, machine, manufacture, or composition of matter, by the use of certain means, is entitled to a patent for it ; provided he specifies the means he uses in a manner so full and exact that anyone skilled in the science to which it appertains can, by using the means he specifies, without any addition to or subtraction from them, produce precisely the result he describes. And if this cannot be done by the means he describes the patent is void. And if it can be done, then the patent confers on him the exclusive right to

use the means he specifies to produce the result or effect he describes *and nothing more*. And it makes no difference in this respect whether the effect is produced by chemical agency or combination, or by the application of discoveries or principles in natural philosophy known or unknown before his invention; or by machinery acting altogether upon mechanical principles. In either case he must describe the manner and process as above mentioned, and the end it accomplishes. And anyone may lawfully accomplish the same end without infringing the patent, if he uses *means* substantially different from those described."

In the *Telephone Cases*, 126 U. S., 533, this Court discriminated sharply between a "discovery" and an "invention," saying:

"In doing this, both discovery and invention, in the popular sense of those terms, were involved; discovery in *finding the art*, and invention in *devising the means* of making it useful. For such discoveries and such inventions the law has given the discoverer and inventor the right to a patent—as discoverer, for the *useful art, process, method* of doing a thing he has found; and *as inventor, for the means he has devised* to make his discovery one of actual value."

So, also, *Corning vs. Burden*, 15 How., 266, 268.

III.

Application of These Principles.

In the light of these principles let us now consider the Westinghouse invention in controversy.

(a.) The first thing which arrests our attention is that the apparatus is not concerned with any manufacturing operation whatever—it is a mere device for applying power to arrest the movement of a railway car.

(b.) We also observe, in the same connection, that the invention in controversy is for the mere purpose of quickening the action of the machine when the engineer may desire so to do.

It may, therefore, be remarked at the outset that it is doubtful whether such an apparatus can, under any circumstances, be the legitimate subject of a patent for a process.

(c.) Pursuing our examination, we observe that the apparatus, generically considered, is not new—it is only an improvement upon prior automatic air-brakes. Its motive power is contained in compressed air, supplied by a pump on the locomotive, and stored up along the train in pipes and reservoirs, ready for use. This motive power is applied, as in the older automatic air-brakes, by admitting it from its storage connections to the brake-cylinder, where its expansive force moves the brake-piston. There is nothing new, therefore, in the power itself, or in the way in which, or subject upon which, it operates. It is the same old power, having the same old mode of operation. There was no new *discovery* involved; for the force of compressed air had been known and used, in various arts, for hundreds of years. If the action of artificially-compressed air could, by any stretch of language, be called “elemental,” in the sense in which that term is used in the *Medart* case, still there is nothing new about it; it is the same old element, producing its result by the same old capacity for expansion. Even if the patent at bar were the first in which the expansibility of compressed air had been utilized for a mechanical purpose, such use could not be monopolized by a patent any more than could the expansibility of compressed steam for driving boats or impelling machinery. (See *O'Reilly vs. Morse*, 15 How. page 115). The invention, therefore, is not in the nature of a “discovery,” nor does it involve any chemical action or any new “elemental” action or effect

whatever. It is simply a *machine*, which, through the presence of a new valve and air-passage, can, when the engineer desires, be made to operate more quickly than it did before such new valve and air-passage were added. A patent for the new valve and air-passage will, therefore, cover all the invention that was made.

The broad idea of producing quick action by the local venting of the train-pipe at each car, cannot be claimed in this patent, because it is the very gist of the invention set forth in the expired patent, No. 217,838, dated July 22, 1879, where Mr. Westinghouse said :

"It sometimes happens with such brake-apparatus, especially in case of accident" (emergency), "that material advantage could be effected by having *all the brakes of the train applied or brought into action simultaneously, or as nearly so as possible*. To accomplish this it is only necessary to make provision for the simultaneous opening of one or more ports in the air-conduit passage *at points not remote from each auxiliary-reservoir*. For this purpose I arrange at such various parts of the air-conduit *or communicating pipes* as may be desired, but by preference at the couplings, relief-valves of the kind shown in the drawings."

All that Westinghouse did, in patent 360,070, was to change the *form* of these relief-valves and operate them by the impact of the triple-valve piston. He simply combined the two old devices, the relief-valve and the triple-valve, adding the former to the latter and calling it his auxiliary-valve 41. It was probably a perception of this fact that caused his counsel to characterize the invention of patent No. 360,070 as a combination of *two machines*. Granting that he got a better effect, *there was no new process*, although there was a new mechanical combination. Boyden adds no relief-valve; he has discovered how to make the old triple-valve do the work without a special relief-valve.

- It is barely possible that the finding out in 1879 that by locally venting the train-pipe or its "*communicating pipes*" under each car throughout the train the serial action of the brakes would be quickened, or rendered simultaneous, "or as nearly so as possible," might be regarded as a "*discovery*," in accordance with the ruling of this Court in the Telephone Cases, 126 U. S., 533, entitling its finder to take out a patent for an art, process, or method. It involves, so far as can be seen, the only thing in the nature of a "discovery" that has ever emanated from Mr. Westinghouse in the brake-art. It either was a "discovery," in the sense of the patent law, or it was not. If it *was*, then the element of "discovery" was exhausted in 1879, and nothing remained to be done in 1886 except to "invent" an improvement in the means for applying the old discovery; if it was *not*, then, assuredly his subsequent application of the same principle by his combination of the old relief-valve with the old triple valve cannot amount to a "discovery." Courts must be logical and consistent in their reasoning. The stream cannot rise higher than the fountain; and if the original discovery and generic embodiment of the principle did not amount to a technical "discovery," surely the mere reapplication of that principle in an improved machine cannot.

(d.) More closely analyzing the new machine, we find it to consist of two parts, or two machines, combined together. Counsel for Westinghouse, in their brief in the Circuit Court of Appeals at Richmond, correctly described it as follows:

After referring to the old triple-valve of the prior art, they said:

"Westinghouse added to and combined with this brake *another brake mechanism*, which, on account of its novel predominant characteristic or function, had given to the whole apparatus its own name of *quick-action* or *emergency* brake,

both names being used. And he so combined these two mechanisms 'the service' and the 'quick-action' that while, in fact, they constitute two machines, they are also included in a *single structure*, and are put into a co-acting or operating mechanical relation with each other, as will presently appear."

The learned counsel saw in the device a "characteristic or *function*" which gives it its name, and the mechanical combination of two machines by which the *function* is effected; but they evidently saw nothing in the nature of a new process. To them, the invention appeared just as we have shown his attorney that it appeared to Mr. Westinghouse and Mr. Bell when they took out the patent in suit.

(c.) Considering, now, the "two machines," viz.: (1) the old plain triple-valve, and (2) the new auxiliary valve and by-passage, we find at once that the first, the old plain triple-valve, acts exactly as it always did—the patent expressly declares this to be true. The triple-valve piston actuates a valve which admits some of the compressed air to the brake-cylinder, just as in the old device. It, therefore, involves no new process or method. Turning next, to the second machine, the auxiliary valve and by-passage, we find the process or method the same as in the other—the piston actuating a valve which admits some of the compressed air to the brake-cylinder. In this instance, the valve admits air directly from the train-pipe to the brake-cylinder; but the admission of compressed air directly from the train-pipe to the brake-cylinder was old, being found in the Boyden patent of June 26, 1883, in all the air-brakes prior to the automatic, and in the automatic air-brake of the Westinghouse patent, 168,359, where it is claimed in claims 7 and 8. Still no new process or method, even in the baldest mechanical sense. Considering, lastly, the combination of the "two machines," we find

that the piston on its half-stroke, operates the one, and, on its full-stroke, both; and that this is the only peculiarity that appears in the combination. *But this is purely mechanical*, due to the peculiar arrangement of the valves, and possessing not a single characteristic of a patentable process or method. There is no "discovery," or "chemical" action, or "elemental" action about it, nor does it take part in producing any product. It is merely the "function" of the described mechanism; and if this is to be regarded as a patentable process or method, then scores of old decisions will have to be overruled, and the patent-law reconstructed on lines before unknown.

The claim requires no such ruling. As we have already remarked, it is, in terms, a claim for a mechanical combination of four old elements, one of which is a triple-valve having a piston. The claim states that this piston on its preliminary traverse admits reservoir air to the brake-cylinder, and on its further traverse admits train-pipe air to the brake-cylinder, but this statement is incorrect—the piston admits no air; it only actuates certain valves, and the valves admit the air. It is also incorrect in implying that the reservoir-air is admitted to the brake-cylinder only on the preliminary traverse; whereas, in fact, it is admitted both on the preliminary and the further traverse—on the preliminary traverse, by the graduating-valve, and on the further traverse, by the main valve. The distinction which the claim points out between the old and the new mechanism is, that the former, on both traverses, admitted only reservoir air, whereas the latter, on its final traverse, also admits train-pipe air—in other words, that, if the two combined machines contained in the new mechanism, (1, the old triple-valve, and 2, the auxiliary-valve 41 and its by-passage) the piston, on its half-stroke, operates the one, and on its full stroke, both. Here, then, is a claim for a *piston*

which consecutively actuates two valves controlling, respectively, two different passages; and the question is whether such a claim is for a mechanical device or for a process.

How can there be any *question* about it? It is purely a mechanical operation, dependent upon the construction and arrangement of the valves and their passages. Given, the particular arrangement of the valves and passages described in the patent, the so-called process is merely the *function* of the apparatus. Hence, it would seem to follow conclusively that the claim, if it means to cover this function, is void, and if it means to cover the mechanism which performs the function, it must necessarily be construed to involve the *new valve* by which the train-pipe air is admitted on the final traverse of the piston. The claim specifies nothing which this Court has ever included in its definitions of a patentable process or method, but it specifies that which, in *Corning vs. Burden* and *Risdon Locomotive Works vs. Medart*, was expressly interdicted from the category of patentable inventions.

We respectfully submit that there are but two ways of looking at this claim—it is either a claim for *mechanism*, or a claim for the *function* of a mechanism. It says, in terms, that it is for a mechanism; and, in the specification, Mr. Westinghouse tells us, as plainly as language can express the idea, that it is *not* for the function but for the *structural features by which it performs* the further *function* of effecting the direct admission of air from the main air-pipe to the brake-cylinder." (See page 2, lines 41-44.) Will the Court hold that it is for a certain thing when Mr. Westinghouse says it is *not* for that thing?

IV.

An Estoppel.

The Court should hold that the learned counsel and experts for Westinghouse have *admitted* the claim to be, not for a process or method, but for a mechanism which includes the new auxiliary valve 41 and its by-passage ; and that this admission is conclusive upon the Court in this cause.

Those gentlemen and their experts have always taken that position. Their contention has invariably been that we infringe, not because we use the same process or method, but because, they say, we use their auxiliary valve 41 in another, but equivalent form. Thus, their expert, Mr. Newbury, says (Transcript, top of page 62) : "My understanding is that Mr. Westinghouse is only entitled to claim the 'mechanical devices' combined together by means of which he is enabled to accomplish the quick-action effect or result ; or, in other words, that he is entitled to claim mechanisms or instrumentalities combined together in substantially the manner set forth. Again, (near middle of page 28) he says : "This claim 2, when read in the light of the specification, as, I understand the matter, is for a combination of four essential elements or devices combined together to form a brake-mechanism." And (near bottom of page 46) he says that in his opinion the Boyden structure infringes the Westinghouse patent in suit, because "*In each there is an auxiliary valve or auxiliary valve device adapted to open direct communication between the main air or train-pipe and the brake-cylinder,*" etc. This is the theory upon which the complainants brought the suit, made up their evidence, and have always argued the case ; and to which the defendants were obliged to direct their defense. *We have never been called upon to meet the charge that we are infringing a process or method, and*

have directed no evidence to that question. We respectfully submit that the complainants, having elected to take the position which they have taken, are bound by that election, even though it should lose them the case; and that the Court, at this late stage of the proceedings, has no right to change the issue. In *Burt vs. Every*, 133 U. S., 349, this Court laid special stress upon the fact that the patentee's counsel, in his brief, had admitted that the claim was to be construed as for a device, and not for a process or method.

Respectfully submitted,

LYSANDER HILL,

Of Counsel for Boyden Brake Co., et. als.

3.45 o'clock P. M.

EXTRACTS FROM THE ORAL ARGUMENT OF HECTOR T. FENTON, IN BEHALF OF THE BOYDEN BRAKE COMPANY.

May it please the Court, the questions which are presented in this record are, apparently, complex; but in point of fact they are exceedingly simple. If your Honors will kindly open the defendants' brief at page 68, you will observe two illustrations, the first of which is patent No. 220,556, the old triple valve, and the second of which is the patent in suit, No. 360,070. The upper picture represents the old automatic triple-valve, and

below it is the same valve exactly, plus the "additional members," consisting of an auxiliary-valve and by-passages, which your Honors will observe colored in red.

The defendants' machine, as plaintiffs will admit, and as the drawings show (opposite p. 69, defendants' reargument brief), has no by-passage other than what it had before in the old art. It has no valve other than what it had before in the old art. But it produces exactly the same result as the complainants' machine does. Why? Because Mr. Boyden discovered, as I shall show to your Honors later on by a parallel case, that the principle of a segregated machine, to wit, these "additional members," was wholly unnecessary to produce this quick-action result. He discovered that he did not need any segregated passage-way leading from train-pipe to brake-cylinder, nor did he need any auxiliary-valve to control that passage-way. How does he get the result? He discovered, may it please the Court, that he could go back to the old art which showed a triple-valve having a check-valve in its piston, and by producing differential pressures in the valve-chamber of the old triple-valve he could make it operate to obtain both the old automatic result and the quick-action result, thereby developing the latent powers of the triple-valve, and wholly dispenses with the "additional members" of the patent in suit or their mechanical equivalent in any form. When you understand that principle of the defendants' machine and when you look at the complainants' patent, you may see for yourselves whether you can reason out from the complainant's patent, or anything shown in his drawings or described in his specifications, the principle involved in the defendant's machine; and if you cannot, that is the end of this case. There is but one single issue involved here, and that is the issue of infringement.

MR. JUSTICE WHITE: Take it for granted that your premise is correct, would not a different rule apply to the patent of Mr. Westinghouse in determining whether these were equivalent to

his patent, and whether he was entitled to a very broad construction of his patent?

MR. FENTON: No, sir; I have in the brief four of the leading cases about pioneer patents—*O'Reilly vs. Morse* and *Morley vs. Lancaster*, and two others—which I will refer to in the course of the argument, when I reach that part of the case, and I shall show your Honors that there never has been a decision in this Court, even in the case of a pioneer patent, which will hold one machine to infringe another, if you reach the conclusion that the second machine does not involve the principle of construction of the mechanism used in the first machine, no matter if it produces the identical results, and no matter if the result was absolutely new with the complainant. That is exactly what this Court said in the case of *O'Reilly vs. Morse*, and it is exactly what you said in *Morley vs. Lancaster*, and what you said in two or three other cases.

MR. JUSTICE BROWN: Is not the decision in *O'Reilly vs. Morse* to a certain extent in conflict with the telephone case?

MR. FENTON: I think not.

My learned colleague asks me to suggest to your Honors, which is true, that the claim in controversy in the Bell telephone case was a method claim, and he will fully discuss that point in his argument.

File Wrapper of Patent in Suit.

I shall not take up the time to discuss the first and the fourth claims. In my humble judgment the first and the fourth claims are too plain to need any discussion; but I will take up the second claim and see what it is. It is the second claim that opens the door to an argument. The second claim reads in this way:

"2. In a brake mechanism, the combination of a main air-pipe, an auxiliary-reservoir, a brake-cylinder and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary-reservoir to the brake-cylinder"

So far as I have read to you I have read only the combination of elements entering into the old automatic brake of 220,556. But the claim goes on to say :

“and which, by a further traverse, admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth.”

That description of the function of the new machine is the only *new thing* in the claim, that is “and which, by a further traverse, admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth.”

What means are to be imported into this claim to carry out this function of admitting train-pipe air to the brake-cylinder, because the elements referred to in the claim, will not perform the function without some means are applied in the claim. That is admitted on both sides.

What are those means? The means is undoubtedly a new “auxiliary-valve,” actuated on the further traverse of the piston, which valve controls a direct passage-way leading to the brake-cylinder.

When Mr. Westinghouse went to the Patent Office with this application, he was met with a rejection of this identical claim 2 in controversy, as well as a rejection of claim 1, which does not appear in this patent and which he erased and substituted a new claim for it. He was met with a rejection of these claims on a reference to Boyden's patent of 1883. He said this in regard to claim 2, and these are strong words :

“It is to be understood that applicant does not seek to broadly claim a device for admitting air directly from main air-pipe to the brake-cylinder.”

Then he goes on to describe several devices which do that.

“When, however, the triple-valve is provided with an auxiliary-valve, operated by its piston, which performs a new function additional to that of the triple-valve as previously employed, it is believed that such combination is wholly novel.”

Now what was his first claim which was *rejected*? His first claim was this:

"1. In a brake mechanism the combination of a main air pipe, an auxiliary-reservoir, a brake-cylinder, and a triple-valve, provided with a device for admitting air directly from the main air pipe to the brake-cylinder, substantially as set forth."

Then what did Mr. Wettinghouse do with this first claim? He substituted a new claim in which he changed the word "device" to "auxiliary-valve, independent of the main-valve." The Patent Office, the Circuit Court, and the Circuit Court of Appeals have all said that when Mr. Westinghouse spoke of the "auxiliary-valve" he spoke of a valve which was "independent of the main-valve" and not one with it, and part and parcel of it—not one valve performing two functions, but a valve independent of the main-valve, not only functionally independent of it, but physically independent of it.

But bear in mind this: that when the Patent Office rejected that original first claim, they also rejected this allowed second claim on the same reference. The two claims were rejected together. It was in order to get that second claim, the one now in controversy, passed by the Patent Office, that Mr. Westinghouse wrote the letter which I read to your Honors a moment ago, and which I will read again:

"When, however, the triple-valve is provided with an auxiliary-valve operated by its piston, which performs a new function additional to that of the triple-valve as previously employed, it is believed that *such combination is wholly novel*." R., p. 718, l. 41.

This letter clearly defines the meaning of claim 2.

This statement conclusively implies an *auxiliary-valve* in claim 2. The contents of this file containing this letter absolutely preclude the possibility of construing the allowed

claim 2 (allowed *after rejection*, allowed *after erasure* of the broad statement, allowed after erasure of this original first claim, and allowed *after receipt of this letter* defining the invention of *this claim 2* as a "combination" of an "auxiliary" valve with the old triple-valve, the piston or its "further" traverse being the actuating means), as being for the triple-valve *per se* admitting the train-pipe air to the brake-cylinder without any "auxiliary-valve" or any mechanical equivalent therefor in any imaginable form.

The Finding of Fact as to Non-identity by Three Tribunals.

We have taken the old triple-valve device which your Honors see, having a graduating valve and a main valve, and we have turned that into a machine which will accomplish the result, by doing what? Have we put in an additional passage-way which we did not have before? No. Have we added another valve that it had not before? No. Have we caused the piston to do anything more or less than it always did? No. We have taken the old triple-valve element, and have partitioned the valve-chambers to create differential pressures therein.

Your Honors will have to hold, in order to find identity, that the partitioning of the valve-chamber of the old triple-valve is the equivalent of adding a separate passageway and an additional auxiliary-valve to control it. *You cannot reason that out from the patent.*

In order to find identity, may it please the Court, the plaintiff will have to satisfy your Honors that, on the record in this case, three different tribunals, one after the other, made a mistake. In order to sustain their proposition that our main valve is the equivalent of their auxiliary and main valves combined; they will have to show your Honors that the Patent Office, when they considered our application for a patent, made a mistake.

Then they will have to take up the record and show to your Honors that Judge Morris, in the Circuit Court, was mistaken. Judge Morris stated that our black valve was a main-valve and not an auxiliary-valve, and that our yellow valve was the graduating-valve. He held that distinctly. They will have to reverse that on this record.

Then they will have to take up the opinion of the Court of Appeals and show to your Honors that the Court of Appeals made a mistake about the same thing, because all three of these tribunals, one after the other, said that our main valve was not the auxiliary-valve of Westinghouse, but was the old and original main-valve of the triple, and that it was none the less a main-valve of the triple, because by partitioning the valve-chamber it performed the additional function of admitting train-pipe air to the brake-cylinder.

On the Question of Non-Identity.

I ask your Honors, in considering the re-argument brief, pp. 43 to 54, to look at the somewhat famous case of *Burr vs. Duryee*, which I have taken the trouble to elaborate in the brief, because, in my humble judgment, that case is exactly on all fours with this.

In *Burr vs. Duryee*, counsel said this:

"Wells was the first who introduced any guiding and directing mechanism, and his introduction of that between the rotating picker and former produced a new machine, viz., the first machine which could successfully make hat bodies from the flying fur by guiding and directing the fur from the picker to the former. He may, therefore, treat as infringers all who used the machine with only a substitute for one of the parts of the combination, performing the office of the part for which it was substituted."

That is precisely the claim that is made here to-day by the learned counsel on the other side. What did Judge Clifford say

in answer to that proposition? He discusses the peculiar characteristics of the Wells invention, and says that it has a tunnel or guide between the picker and the rotating cone. Then he says that in the defendant's machine there is no tunnel or directing mechanism; just as in ours, we have no auxiliary-valve or separate and distinct segregated passage-way. We use the old main-valve and the old passage-way for reservoir-air to transmit train-pipe air to the brake-cylinder. Then he goes on to say:

"Now, an infringement involves substantial identity
 "whether that identity be described by the terms, same
 "principle, same *modus operandi* or any other. It is a
 "copy of the thing described in the specifications of the
 "patentee, either without variation, or with such varia-
 "tions as are consistent with its being in substance the
 "same thing. If the invention of the patentee be a
 "machine, it will be infringed by a machine which
 "incorporates in its structure and operation the sub-
 "stance of the invention; that is, by an arrangement of
 "mechanism which performs the same services or pro-
 "duces the same effect in the same way, or substantially
 "the same way." (1st Wallace.)

He says here, that the argument in that case, which is substantially similar to the argument in this case, is an argument not that the two machines are alike in principle of construction, but is an *argument that they produce the same result*, and he says that when you argue that because two machines produce the same result they are equivalent, it is an abuse of the term "equivalent."

If we apply the test which was applied in *Burr vs. Duryee* to this case, your Honors will see how forcible the argument is here. Suppose that Mr. Westinghouse's patent to-day was a reissued patent? I have shown you from the original patent that the machine which he describes is a combination of these old elements, plus these additional members. Suppose he had reissued that patent and described this thing? Would your

Honors hesitate for an instant to say, upon a comparison of the two things, that he was taking a reissue for a *different* invention? Is it any the less a different invention because it is made the subject-matter of a subsequent patent to an independent inventor? Certainly not.

The Burden of Proof on Plaintiff.

I now desire to call your Honors' attention to one other matter which seems to me to be of controlling importance. You have here a single issue in this case, an issue of fact: Are these machines identical or are they different? The patent is not attacked for want of novelty. It is not attacked for invalidity in any respect upon any proper construction of its claims; but it is a pure, bald issue of fact, infringement or non-infringement.

Now the burden of proving that, as we all know, is on the plaintiff, who seeks to discharge that burden by his testimony in chief. And when the defendant comes into court and lays down their patent with broad claims in it, differentiating this device from that device; when, upon the face of the defendant's patent you see that the patent itself is based upon this question of identity, then, I say, that under the decisions of this court which are cited in full in the brief, the latest of which is the *Miller vs. Eagle Company*, 151 United States, the burden of proof is shifted back on the plaintiff.

Have they answered it? In this case you have heard remarks made by learned counsel who opened the case for the Westinghouse Company, that Mr. Westinghouse said this and Mr. Westinghouse said that. The Mr. Westinghouse who said these various things was not Mr. Westinghouse the patentee, but his brother. Mr. George Westinghouse, the inventor, is one of the plaintiffs in this case. The plaintiffs are the Westinghouse Air Brake Company and George Westinghouse, Jr. Has Mr. George Westinghouse dared to come upon the stand and say that his

invention included the invention described and claimed in the Boyden patents? No, sir; he is silent.

Has Mr. Boyden come upon the stand and told you the evolution of his device in controversy. Yes, sir, frankly, and he has been cross-examined at length.

When you consider upon whom is the burden of proof; when you consider the file and contents of the application for the patent in suit; when you consider the granting of the patent to us raising a *prima facie* conclusion of radical differences; when you consider the broad claims in our patent, which the patent office must have passed upon and did pass upon; when you find that even under their own theory the Circuit Court has said that our main pop-pet-valve 22 is not the auxiliary valve 41 of the patent in suit; when you find that the Court of Appeals has said the same thing upon this issue of fact, upon that vital question in the case, you must also consider that you have no answer from Mr. George Westinghouse denying our proposition. You have Mr. George Westinghouse absolutely silent upon that question. I say, may it please the Court, that he has not discharged the burden of proof, and that the case ought to be with us.

EXTRACTS FROM THE
ORAL ARGUMENT OF LYSANDER HILL
 ON BEHALF OF THE BOYDEN BRAKE CO.

May it please the Court, I shall commence my remarks by referring to a point which was suggested by one of your Honors yesterday; to wit, the condition of the law as to what are and what are not pioneer inventions.

As I understand the law, there are four great decisions of this Court which have substantially laid down all the law that is involved in this case. Those four cases are: *O'Reilly vs. Morse*, 15 Howard; *Burr vs. Dwyer*, 1 Wallace, and *Morley vs. Lancaster*, 129 United States, which were cited by my friend, Mr. Fenton, and the more recent case of the *Incandescent Lamp Patent*, 161 U. S.

In *O'Reilly vs. Morse*, the great Morse telegraph was involved. In the patent for which Mr. Morse had made a claim for the transmission of intelligence to a distance by means of a current of electricity, irrespective of the means employed. This Court, as your Honors are perfectly well aware, held that claim (the 8th) to be invalid, as being a claim for an effect or result, and such has been the law, not only in this court, but following it in all other courts of this country, and in England too, from that day to this.

In the English courts, prior to the case of *O'Reilly vs. Morse*, the question had arisen in the great case of *Neilson vs. Harford*, on the hot-air process of smelting iron. Neilson made a very broad claim, in that case, as your Honors will remember, and the English courts, after great litigation and after argument by the most eminent counsel in the realm, came finally to the conclusion that the patent could not be sustained as for the

result of manufacturing iron by the use of the hot-air process; but that the patent was to be treated as a patent, practically, for a combination of mechanical elements which were used by Neilson in producing this result. Upon looking at his patent and the description given therein, they found that the combination of elements which he used consisted of three in number, to wit, the smelting furnace in which the iron was to be treated; a fan blower or equivalent air-pump for creating a blast of air, with a pipe leading from the blower to the smelting furnace; and, interposed between the fan blower and the smelting furnace, a heating device to heat the pipes through which the air passed to the furnace, so that the air started in its movement by the fan blower and heated in its course by the heating device, would enter the smelting furnace hot and produce the result.

The English Court held that if the Neilson's patent was to be considered broadly for the means of applying hot air in a blast furnace, it would be invalid as for a principle, or a result or an effect; and in order to validate the patent it was necessary to confine it to the means which were employed by Neilson for effecting the result. Those means were the combination of three elements, the fan-blower, the smelting furnace and the heater arranged between the blower and the furnace.

That case practically notified the world that if anybody else found any other way of applying hot-air to a blast furnace, any different way of using even these elements it would avoid the patent. For example, if it had been found practical to put the fan-blower between the heater and the furnace, that would, under their construction, have avoided the claims of the patent. The combination must be a combination of those three elements arranged in that way.

That has been the law of England from that day to this. They do not allow, any more than this Court allows, a claim for a result or effect, but they limit the inventor *to the means* by which he produces that result or effect and to the means

or their mechanical equivalents which he describes in his patent for producing it. Such was the doctrine of the case of *O'Reilly vs. Morse*, in this court.

The question was asked yesterday by Mr. Justice Brown, whether there was not something in the Bell telephone decision which had modified that theory of the law, to which question I now desire to answer most emphatically, No. There is nothing in the Bell telephone decision that modifies *O'Reilly vs. Morse*, in any respect whatever, as I understand the decision, and I think I understand the facts upon which the decision was based. The Bell telephone patent raised a different question altogether. The broad claim in that patent was *not* for an effect or result. It was for a method. Bell was not claiming the transmission of vocal sound to a distance by a current of electricity, as Morse was. If he had made *such* a claim this Court would have immediately pronounced the patent invalid, on the same ground that they held Morse's eighth claim invalid. Helmholtz, long before Bell's time, had discovered the fundamental laws of sound. He had discovered the form of sound waves and he had found the peculiar fact that sound waves in the air are not abrupt, but are undulatory; that each wave is in form a combination of what musicians call *crescendo* and *diminuendo*. It commences and rises like a wave of the sea, and then settles down again to a level, gradually and not abruptly. Sound waves are capable of being delineated graphically by serpentine lines, by sinuous waved lines, such as appear in a rope when one end is fastened to a post and you take the other end in your hand and wave it up and down. Helmholtz discovered that *that* was the peculiar form which sound waves take in the air. Before Bell's time, Philip Reis, in Germany, had attempted to invent a telephone. He was a philosopher, and was perfectly familiar with the Helmholtz theory of sound waves. He undertook to transmit sound, not by putting the current on the line in the form of an

undulatory current, but by a sharp make and break current, and to transfer that into undulations in the diaphragm. That was his attempted method of reaching the result. It failed because the receiver was incapable of transmitting the sharp, abrupt make and break current on the line into gradual undulations and sinuous movements.

Bell, as held by this Court, evolved another theory. He evolved the theory that if he could go back one step from Reis and take the current on the line wire and put that current into the form of undulations, he could then accomplish the result, because the receiving diaphragm would then take the same vibrations as the current on the line. Bell therefore provided *a method* or mode of transmitting speech, not as Reis had done, by a make-and-break current, and by seeking to transform that into undulations at the receiver, but by the other method of putting on to the telephone line itself a current in the form of an undulation. He skillfully drew his patent to cover that as his method—not to broadly cover a current of electricity—but to cover the method of transmitting speech by putting upon the line wire these current undulations which could be graphically described by sinuous or serpentine curves, and his claim was for that method.

I hold in my hand Volume 126 United States Reports, in which Bell's claim was discussed by the Court, and on pages 531, 532 and 533 your Honors will find the point at which the Court discussed that question.

The Court said :

“In this art—or, what is the same thing under the
“patent law—this process, this way of transmitting
“speech, electrically, one of the forces of nature, is
“employed: but electricity left to itself will not do
“what is wanted. The art consists in so controlling the
“force as to make it accomplish the purpose. It had
“long been believed that if the vibrations of air, caused
“by the voice in speaking, could be reproduced at a dis-

"tance by means of electricity, the speech itself would
 "be reproduced and understood. How to do it was the
 "question.

"Bell discovered that it could be done by gradually
 "changing the intensity of a continuous electric current,
 "so as to make it correspond exactly to the changes in
 "the density of the air caused by the sound of the voice.
 "This was his art. He then devised a way in which
 "these changes of intensity could be made and speech
 "actually transmitted. Thus his art was put in a condi-
 "tion for practical use.

"In doing this, both discovery and invention, in the
 "popular sense of those terms, were involved. Discovery
 "in finding the art, and invention in devising the means
 "of making it useful. For such discoveries and such
 "inventions the law has given the discoverer and
 "inventor the right to a patent—as discoverer for the
 "useful art, process method of doing a thing he has
 "found, and as inventor for the means he has devised to
 "make his discovery one of actual value. Other inventors
 "may compete with him for the ways of giving effect to
 "the discovery, but the new art he has found will belong
 "to him and those claiming under him during the life of
 "his patent. If another discovers a different art or
 "method of doing the same thing, reduces it to practical
 "use, and gets a patent for his discovery, the new dis-
 "covery will be the property of the new discoverer, and
 "thereafter the two will be permitted to operate each in
 "his own way without interference by the other. The
 "only question between them will be whether the second
 "discovery is, in fact, different from the first.

"The patent for the art does not necessarily involve a
 "patent for the particular means employed for using it.
 "Indeed, the mention of any means, in the specification
 "or descriptive portion of the patent, is only necessary to
 "show that the art can be used: for it is only useful
 "arts—arts which may be used to advantage—that can be
 "made the subject of a patent."

The Court is now speaking of claims for a method. Passing to the next page, the Court refers to this very case of *O'Reilly vs. Morse*, and says:

"In *O'Reilly vs. Morse*, 15 Howard, 62, it was decided
 "that a claim in broad terms for the use of the motive
 "power of the electric or galvanic current called electro-
 "magnetism, however developed, for making or printing
 "intelligible characters, letters or signs at any distances,
 "although a new application of that power first made by
 "Morse, was void because it was a claim 'for a patent for
 "an effect produced by the use of electro-magnetism,
 "distinct from the process or machinery necessary to
 "produce it'; but a claim for 'making use of the motive
 "power of magnetism when developed by the action of
 "such current or currents as set forth in the foregoing
 "description, as a means of operating or giving motion
 "to machinery, which may be used to imprint signals
 "upon paper or other suitable material, or to produce
 "sound in any desired manner for the purpose of tele-
 "graphic communication at any distances,' was sustained.
 "The effect of that decision was, therefore, that the use
 "of magnetism as a motive power, without regard to the
 "particular process with which it was connected in the
 "patent, could not be claimed, but that its use in that
 "connection could."

The Court further says, at the top of page 535:

"We see nothing in *Morse's* case to defeat *Bell's* claim.
 "On the contrary, it is in all respect sustained by that
 "authority."

There is nothing in the case of *O'Reilly vs. Morse* that conflicts or interferes with the view of the law which this Court expressed in the Bell telephone patent. There is no conflict between the two decisions. In the Morse case he simply sought to claim the use of the electric current, generally, without any reference to a method, the machinery or means for marking signs at a distance. In Bell's case, if the Court is correct

in its conclusions, there was the discovery of a certain method by which an undulating current of electricity which when transmitted under a condition which he describes and which was the subject of his invention, would accomplish that result, and his claim was made for that method, and was sustained as being for that method.

The case of *O'Reilly vs. Morse*, as I understand it, has never been doubted or modified in any respect whatever, either in this country or in England since the decision was made in 1853. On the contrary, it has been repeatedly affirmed, both here and there.

I would like to read to your Honors the language of the Court in the case of *O'Reilly* against *Morse* and embody it in my argument, because I am satisfied that no lawyer at the bar can state the principle of the law more clearly and more logically than it is stated in this opinion :

“Whoever discovers that a certain useful result will be produced, in any art, machine, manufacture or composition of matter, by the use of certain means, is entitled to a patent for it; provided he *specifies the means* he uses in a manner so full and exact, that any one skilled in the science to which it pertains can, by using the means he specifies, without any addition to or subtraction from them, produce precisely the result he describes. And if this cannot be done by the means he describes, the patent is void; and, if it can be done, then the patent confers upon him the exclusive right to use the means he specifies to produce the result or effect he describes, and nothing more. And it makes no difference, in this respect, whether the effect is produced by chemical agency or combination; or by the application of discoveries or principles in natural philosophy, known or unknown before his invention; or by machinery acting altogether upon mechanical principles. In either case

“he must describe the manner and process as above mentioned and the end it accomplishes, and *any one may lawfully accomplish the same end without infringing the patent, if he uses means substantially different from those described.*”

No principle of law was ever stated more clearly by any court than this principle is stated by this Court.

Burr vs. Duryee Case.

The case of *Burr vs. Duryee* has been referred to by my learned friend, Mr. Fenton. That case was also a case of a pioneer invention or discovery—a pioneer patent.

Your Honors will find, if you choose to refer to it, in Mr. Fenton's re-argument brief, p. 52, a full illustration of the machines in that case, pointing out the difference caused by defendant omitting the interposed guiding tunnel. The defendant made a different combination and avoided the combination of the patent, and this court held that the patent, although a *pioneer* patent, did not cover the machine *when that element was omitted*. It was an essential element of the combination described in the patent, and this court was obliged to hold that its use was essential to the patent, and that he who discovered how to omit it avoided the patent. This court was obliged to so hold in order to be consistent with its own repeated decisions.

Incandescent Lamp Case.

The incandescent lamp case was a recent case decided by the judges who are now on the bench, or nearly all of them, about two years ago. That is a case which, in my judgment, is “on all fours” with the case which is before you today. Your Honors will remember it, for you heard and decided it. Sawyer and Man had discovered that carbonized paper fibre was a useful element out of which to construct the filaments of incandescent electric lamps. They took out a patent upon it,

and as paper fibre is a vegetable substance, the attorney who drew their patent thought that he could broaden their patent for them and make it squarely cover all possible infringements by taking it in its character as a "*vegetable fibre*" and describing the discovery or invention as a discovery of a *vegetable fibre*. The claim, therefore, was drawn for the use of "carbonized vegetable fibres" or textile material in constructing the filaments of incandescent lamps. When that case came before this Court, your Honors held that Sawyer & Man had not discovered all vegetable fibres or the utility of all vegetable fibres for that purpose. They had discovered the utility of *paper* fibre for constructing the filaments of incandescent lamps, but yet that fact did not entitle them to go beyond their discovery of paper fibre and include all kinds of vegetable fibres within the range of their discovery. They had *not* discovered that all kinds of vegetable fibres would produce the result.

It turned out upon investigation that a good many vegetable fibres were not suitable for making filaments for incandescent lamps, but only some of them were. Among those which were of a proper character for that purpose Edison afterwards discovered that the fibre of a certain bamboo which grows in Japan and the Eastern islands was peculiarly fitted for that purpose, and was better, even, than the paper fibre. After investigating all the vegetable fibres that he could learn of or bring under his processes of investigation in his laboratory, he settled down upon *that bamboo fibre* as the best fibre known or attainable for the purpose, and he patented it and used it. Of course Sawyer & Man, the owners of the patent, brought suit against the Edison Company for an infringement of their patents. Edison was using "carbonized vegetable fibre" material, and their patent broadly covered carbonized vegetable fibre material.

Why was it not an infringement? Sawyer & Man were the first to use carbonized vegetable fibre in the form of this

paper fibre. But your Honors told the complainants there, Sawyer & Man, or their representatives, that the discovery that paper fibre was suitable for that purpose was not a discovery that *all vegetable* fibres were suitable for the purpose, and that their discovery was limited to paper fibre. They had discovered *that*, and they had not discovered anything else; and although the terms of their patent were broad, covering the whole vegetable world, you limited them right down to carbonized paper fibre, upon the ground that *that* exhausted their discovery. The defendant, in that case, was held not to infringe.

I say that the principle of that case is "on all fours" with the case here, and that is the general principle which runs through all these pioneer cases, or cases of so-called pioneer patents.

A man who has made a discovery is entitled to a patent commensurate with that discovery. If the terms of his patent or the claims go beyond the actual invention which he has made, they must be restricted, by construction, and confined to the invention which he has made. Bell's claim was for the method of putting the undulatory current on the line wire. It was not necessary to restrict that, because *that* was the invention which was made. In the case of the hat-body machine, the claim was for a combination of three elements, the picker, the guiding tunnel, and the receiving cone. That was the combination described. But your honors held, in that case, that if anybody left out one element of *that combination* they avoided an infringement.

In the Neilson case, in England, the Court construed the invention as including three elements, the fan-blower, the heater and the furnace, arranged in that relation, and they held that if anybody omitted any one of those elements, such omission avoided the combination.

These were all "pioneer" patents; but a pioneer patent is limited to the invention which it describes. Because it is a

pioneer patent it is not to be taken as broadly covering, not only what the man invented, but everything also that others could invent to accomplish the same result. If anybody could discover to-day, or hereafter, that speech could be transmitted telephonically by the use of some other current than the undulatory current on the line, the inventor would be entitled to a patent free of the Bell patent. The Court so held and so stated, in terms, in their decision. Bell's monopoly was based upon the fact that during the seventeen years of the existence of the patent nobody did discover any other way of getting electric transmission of speech except by the use of this undulatory current on the wire; but, *non constat*, that might be discovered at some future time. But it has not yet been done, and Bell's patent, while it stood, covered all the ways known to us for the transmission of electric speech; but the Court left it free, and his claim left it free, for anybody to discover some other way of producing that result, and to patent it and maintain the patent.

Let us apply that principle to the patent here. Mr. Westinghouse made a certain invention in 1886. He discovered that if he would take the old triple-valve, without changing it, which did not produce that rapid serial effect, and would make another passage-way from the train-pipe to the open atmosphere or to the brake-cylinder—for he first put it in the form of a passage-way to the atmosphere, and next in the form of a passage-way to the brake-cylinder—and control that new passage-way by a *new valve* which had not been on the apparatus before, and operate that new valve with the triple-valve piston, so that in making the emergency stop the triple-valve piston would move out and strike and unseat that new valve, compressed air could be admitted into the brake-cylinder from the train-pipe. *That* was his (Westinghouse) invention. There is no other to be found in his patent. His invention consisted in that new combination.

He patented that combination. The patent cannot go beyond it, because there was nothing beyond it described. If his

patent in terms goes beyond that combination, your Honors should say to him just as you said in effect in the case of *Sawyer and Man*: "You have drawn a patent which goes beyond your invention, and includes what you did not discover or invent; and your patent, therefore, must be limited back to your invention by construction."

Mr. Boyden discovered that the old triple-valve *per se* possessed latent powers unknown and undeveloped, and he invented means, partitioning the valve-chamber, by which those latent powers were brought into active service to vent the train-pipe air simultaneously with the admission of auxiliary-reservoir air to the brake-cylinder. By Boyden's invention the old main-valve of the triple-valve was made to vent both the airs. Therefore it is obvious that Boyden uses the old triple-valve to vent the train-pipe air, whereas Westinghouse invented "additional member" to the triple-valve, which forms no part thereof. Plainly the case at bar is on all fours with the Incandescent Lamp case.

**The Patent in Suit not a Pioneer, not a Success,
nor is it Used.**

But when Mr. Westinghouse made that combination of this patent 360,070, here in suit, he did not accomplish what my learned friend, Mr. Christy, told you yesterday by means of that patent. Mr. Christy said that the invention consisted in reducing the time of the application of the brakes throughout the length of the train from twelve seconds to two seconds. It is true that was done, but it is *not* true that it was done with this patent. This patent did not by any means reduce the time of application from twelve seconds to two seconds. The reduction of time from 12 seconds to 2 seconds was accomplished by a patent taken out by Mr. Westinghouse a year later, patent No. 376,837, dated in January, 1888. Under the patent in controversy Mr. Westinghouse undertook to accomplish the result of *preventing*

shocks on long trains. Did he do it with this invention? No. The result shown by the tests at Burlington, Iowa, was to more than double the amount of the shock to the train. Instead of the device of this patent tending to prevent and reduce the shock, it *increased* it to such a ratio that while in the first test made in 1886 with the old triple-valve the shock was in the proportion of 49—the slidometer moved 49 inches in response to that shock—the second test, in May, 1887, when Westinghouse came to try the Device of the patent here in suit, the shock was 103 inches, or more than double that under the old triple-valve. The device was then and there withdrawn as unfit and unsafe for use, and it never was used afterwards. He then and there abandoned the use of the structure and never resumed it. The device of this patent in suit has never been advertised by him to the world. You cannot find it in any catalogue issued by the Westinghouse Company from that day to this. It never has been manufactured from that day to this, and it never has been sold by that company from that day to this. The reason for that is it was deemed too dangerous to sell.

On that point, I wish to read the testimony of Mr. Herman Westinghouse, the brother of Mr. George Westinghouse, who did not testify in his own behalf. Commencing on page 117 of the transcript:

“The result of these tests were disappointing. None
 “of the competitors, in the estimation of your committee,
 “did satisfactory work, owing to the *violent shock pro-*
 “*duced in stopping.*”

After the experiments made at that test, the Master Car Builders' Committee in charge of the tests reported in these words:

“At the conclusion of the 1886 trials, the committee
 “felt that to sum up any results in the face of so large a
 “field for improvement, could not but be unsatisfactory,
 “and while a wonderful advance has been made in the

"brake problem, as will be seen by a comparison of the stops of each year, *the 1887 tests* (with the device of patent in suit) *apparently leave the field for improvement open as wide as in 1886.*"

Then they go on to recommend, *not* this brake, but an electric brake, and they say :

"While we are not prepared to make any definite recommendation at this writing as to what freight train brake should be generally adopted, our present information, derived from the recent tests, points to two conclusions:

"1st. That the best type of brake for long freight trains is one operated by air, and *in which the valves are actuated by electricity.*"

That type of brake was shown, and it was found to answer the purpose perfectly. There was absolutely no shock when the air was admitted to the brake-cylinder by the action of valves actuated by electricity. Then follows on pages 127 and 128 a tabulated statement of the *slide* of the shock-measuring instrument, and the degree of the shock in the 1887 test. With the Westinghouse fifty-car train the shock in inches is shown to be 103, afterwards 70 $\frac{3}{8}$, and afterwards 70 $\frac{1}{2}$, and then this device of patent in suit was dropped.

The committee then says that the brilliancy of the Westinghouse record—that is, of the air-brake test—"was completely spoiled by the fearful shock given at the rear end of the train."

The same train was then tested electrically, with the following results :

Shock denoted by the instrument in inches, *none*. There were four tests and no shock whatever, not even an inch, while that of the Westinghouse device, under the patent in controversy, was 103 inches.

Mr. Herman Westinghouse, in his testimony, says :

"The conclusion of the 1887 trials, instead of furnishing to the railroad the desired information upon which

"to take prompt and reasonable action, seemed to show
 "that *much yet remained to be done* before it could be
 "safe to make a practical move in a matter of so great
 "importance. These sentiments are clearly expressed in
 "the committee's conclusion of the 1887 trials."

Somewhere in the record, although my eye does not light upon it now, he states that the train with the device in suit was withdrawn from further test on the ground that it *was not deemed prudent to use it*, and it was not tested again. In the course of his testimony he says that they have never made these brakes from that time to this, nor sold them since, nor advertised them in their catalogue.

This, then, is their so-called "pioneer" patent, a patent which did not accomplish the result and which doubles the injury. Moreover, it is not a pioneer patent in the sense of being the first to utilize or to state the principle of quick-action—the local venting of the train-pipe at each car. *That was* fully and completely stated in the prior patents of Mr. Westinghouse, in 1879, No. 217,838. In that patent a full description was made of the effect of venting the train-pipe at numerous points along the train, not remote from the auxiliary-reservoir of each car, and this patent says that the injuries resulting from the old system are avoided by the use of such expedients and a *nearly simultaneous* application of all the brakes is produced.

My friends on the other side say of this patent 217,838 that it was not practical. They say they did not make it and put it into use. We answer, they did not make this device of the patent here in suit and put it into use after its defects were shown at Burlington. *If the 1879 device is not practical for that reason, neither is this, for the same reason.*

But the defendants in this case made a complete set of 217,838 suited for fifty cars, and tested them at their works in the presence of complainants' counsel, and under all the conditions that could be demanded for their use. They were found to work just as well as this device in suit works. My brother

Christy said here yesterday that while the valve of that patent 217,838 could be opened, *it could not be closed*. Mr. Christy was not present when they were tested; he is mistaken. There is not the slightest trouble in closing that valve. In these experiments made in Baltimore with the fifty brakes of that patent, the valves were closed as easily as they were opened. That is a mere fiction of my brother Christy's imagination. That device will both open and close the valves, and it is a "quick-action" device.

Mr. Westinghouse, himself, was not even the first to discover the utility or principle of action of that relief-valve, which is the fundamental law of quick-action. The prior English patent to Sanders, in 1879, referred to by Mr. Newberry, the Westinghouse expert, in the course of his testimony, also exhibited that kind of a quick-action relief-valve. They are all quick-action valves, because their effect is to locally vent the train-pipe under the different cars and produce quicker action.

"Shock," in stopping a long train quickly, is caused from the fact that without those local vents the air has to travel the whole length of the train-pipe to get out at the front end; but if there can be numerous vents provided along the train-pipe, the air will escape much quicker and thereby cause the application of the brakes much more quickly. And wherever those local vents are provided in an air-brake which is capable of operation, the whole principle of quick-action devices is involved and made public, and it then becomes merely a question of the form of a device or the construction of a device. He who subsequently takes out patents on a quick-action device must limit his invention or claims to the construction of his device, or to his particular combination. I do not mean to say that he must limit it down to the structural form, in that one thing must be round and not square, or anything of that kind; but I mean that he must limit it to the combination of elements which he invents as a means for obtaining quick-action.

May it please the Court, increased power in the brake-cylinder was not the essential object of this invention. There was no trouble in getting all the power that was necessary under the old, plain triple-valve. You cannot, in these air-brakes, increase the power beyond a certain degree. If you apply the brakes with too great power you slide the wheels of the cars on the track rails, and if you slide the wheels of a car even once you are liable to ruin every wheel by wearing flat spots on the wheel rim. You have to carefully guard against that, and you must apply the brake power to such an extent only as will check the wheels and not stop their rotation—not slide them. If you apply more than fifty or fifty-five pounds air-pressure in the brake-cylinders on these levers, as they are now constructed, you will be liable to slide the car wheels and thereby ruin them.

There was no trouble in getting fifty or fifty-five pounds of air-pressure with the old automatic brake; not the least. The old automatic brake gave a pressure in the brake-cylinders of forty or fifty pounds, and more if you wanted it. All you had to do to get greater pressure was simply to enlarge your auxiliary reservoirs. There was no trouble about that. Ordinarily the auxiliary reservoir is about double the capacity of the brake-cylinder. If it was only of the same capacity as the brake-cylinder, then when the air from the reservoir was admitted into the brake-cylinder, if there was seventy pounds of pressure in the reservoir, it will equalize in the brake-cylinder at thirty-five pounds, one half in each. Now, plainly, if the capacity of the reservoir is made twice as large as the brake-cylinder, and there was seventy pounds in the reservoir, the air will equalize in both at about forty-seven pounds of pressure. Make the auxiliary-reservoir a little larger, and on equalizing the air-pressure you would have fifty or fifty-five pounds in your brake-cylinder.

In the argument of the case in the Court of Appeals below, this fact was admitted by my learned friend, Mr. Betts, on the

other side. I hold in my hand a printed report of the arguments before the Circuit Court of Appeals at Richmond, where my brother Betts says:

"But here let me say that quick-action does not involve
 "greater power of the brake. It is not a question of
 "greater force of brakes as applied to the brake-shoes of
 "any individual car. The force with which the brake-
 "shoes are applied to any individual car is no greater
 "with the Westinghouse quick-action brake, which is in
 "controversy here, than it was with the old automatic
 "brake."

So increase of power was not the point. The point was to get
 "quick-action."

What Mr. Westinghouse was after was to *vent the train-pipe quick*, so as to produce rapid serial action in the brake, and *thereby prevent shock at the end of a long freight train*. He did not accomplish it with this patent. He accomplished it with a subsequent patent taken out in 1888—No. 376,837—a patent we are not sued on.

Why did they fail to accomplish it here? And why did they finally accomplish it there? Because the second patent, the patent of 1888, the successful one, went back, in plain terms, to the old relief valve of 1879 and adopted that form, which had a supplemental piston.

When Mr. Westinghouse put *that* old 1879 device into his triple-valve case he achieved success, and not till then. In the patent in suit he did not put in that device.

In the latter patent, after the device in suit had failed at Burlington, and had been discarded, Mr. Westinghouse, according to the record, spent about four months in trying to discover how he could make a valve that would operate. It was no easy matter. Mr. Herman Westinghouse testifies at considerable length as to the great difficulties involved in overcoming the troubles experienced in the Burlington tests, and in devising a

new brake which would relieve the shock; and it was only after car load after car load of materials had been sent from Pittsburgh to Burlington, and the whole summer of 1887 had been spent in working upon it, that it was discovered how to accomplish the result. Herman Westinghouse says when he did accomplish that result he produced a brake which has become the standard brake since that time. That is true. What did he produce by that four months of effort? What did become of the standard brake from that time on? We answer the device of patent 376,837, dated January, 1888. The Westinghouse brake of commerce to-day. You do not see any slide-valve in this latter device actuated by the further traverse of the piston, but you have here a reproduction of the old device of the 1879 patent, 217,838, the relief-valve patent. You have the supplemental piston and the valve taken bodily from the old device of 1879. (See illustrations p. 89, re-argument brief for Boyden.)

When he got that device, which consisted simply in transferring this old relief valve from the train-pipe, as he had it in 1879, to the triple-valve casing, and putting it in a separate chamber and operating that supplemental piston by air let in through the main-valve, he got a successful device. But so long as he relied on the auxiliary-valve, actuated by the further traverse of the piston, he was totally unable to accomplish the result. When he got the valve of patent 376,837 of 1888, and found that it accomplished the result in two seconds, that form of valve, 360,070, the patent in suit disappeared.

We are not sued on the patent of 1888. The suit against us is on the 1887 patent, which has been discarded by Westinghouse himself. He has not brought any suit against us on the successful patent.

Supreme Court of the United States

OCTOBER TERM, 1895.—Nos. 847 and 878.

BOYDEN POWER BRAKE COMPANY—

GEORGE A. BOYDEN, President ;
CHARLES B. MANN, Secretary ;
WILLIAM WHITRIDGE, Treasurer—

AND

BOYDEN BRAKE COMPANY,

AND

BOYDEN BRAKE COMPANY,
Appellees.

Cross-Appeal.

PETITION.

THE PETITION OF BOYDEN POWER BRAKE COMPANY, GEORGE A. BOYDEN, PRESIDENT; CHARLES B. MANN, SECRETARY; WILLIAM WHITRIDGE, TREASURER; AND BOYDEN BRAKE COMPANY, PARTIES TO SAID APPEAL AND CROSS-APPEAL.

Your petitioners humbly pray that said cause, which was brought to this Court by a writ of *certiorari*, issued on the 27th day of January, 1896, to the Circuit Court of Appeals for the Fourth Circuit, may be advanced and set for hearing at an early date, to be fixed by this Honorable Court, the circumstances of this case being special and peculiar, within the meaning of Rule 26, and not liable to furnish a precedent for other cases.

The grounds upon which your petitioners pray this relief are given below, together with brief statements of facts necessary to the proper understanding of them. They are as follows, to wit:

1. The automatic air-brake for railroad cars was originally invented by George Westinghouse, Jr., about the year 1872, and his broad patent for it expired in 1889. It operated by means of what was called a "triple valve." It was well adapted for short trains, such as passenger trains; but when applied upon long freight trains it proved impracticable, because, in stopping the train suddenly with the full force of the brakes, in cases of emergency, the interval between the setting of the brakes on the extreme forward cars and the extreme rear cars was sufficient to produce great "shocks" upon the latter, or, in other words, sufficient to allow the rear cars, while yet free from brake pressure, to run forward at full speed and collide, with great violence

and often disastrous results, against the forward cars already checked in their movement by the speedier application of their brakes.

The application of electricity had made the fact known that, if all the brakes on a long train be set with full force at substantially the same moment, all the cars will "slow down" simultaneously, and there will be no "shock." The employment of electricity, however, to operate the valves of an air-brake apparatus was objectionable; and it became desirable therefore, that other means should be contrived whereby the interval between the application of the brakes upon successive cars should be reduced sufficiently to prevent the destructive end collisions of the rear cars when applying the brakes suddenly with full force.

George Westinghouse, Jr., contrived, and on March 29th, 1887, patented, in his patent No. 360,070, one means designed to accomplish this result. His invention consisted in a new "auxiliary valve," actuated by the piston of the old triple valve, to locally reduce the pressure in the air-pipe in cases of emergency, and thus quicken the application of the brakes upon the next succeeding car. This patented apparatus did not work satisfactorily on long trains, but *confessedly increased* instead of reducing their "shocks." He subsequently improved it by providing a supplementary chamber and special piston for operating the auxiliary, or emergency, valve, and obtained a patent for this improvement, No. 376,837, dated January 24, 1888. As thus improved it gave entire satisfaction, and has gone largely into use. Some 400,000 cars, according to the statements of complainants' counsel, having already been fitted up with it. Suits on both of these patents were subsequently brought in the Southern District of New York against the New York Air-Brake Company, who used the *auxiliary* emergency valve, the *supplementary chamber* and the *special piston* to operate it; and the Courts rightly sustained both patents and held the New York Air-Brake Company guilty of infringement. In their opinions in those cases the Court held that the invention of patent 360,070 consisted in the

new *auxiliary or emergency valve*, while that of patent 376,837 consisted in the new *supplementary chamber and piston* actuating that valve.

In 1888, George A. Boyden, one of your petitioners, invented another and radically different means for accomplishing the same result. He did not resort to the use of an "auxiliary" or special emergency valve at all, as did Mr. Westinghouse, but contrived to *make the old triple valve itself* produce the desired result, without the aid of Mr. Westinghouse's device or any mechanical equivalent thereof. For this invention, he received broad generic patents, dated August 16th, 1892, upon application filed September 30th, 1889. Your petitioners, Boyden Power Brake Company and Boyden Brake Company, became successively the owners of these Boyden patents, and have put the invention into successful practical use on a number of railroads.

On the 12th day of December, 1889, George Westinghouse, Jr., and The Westinghouse Air-Brake Company began suit against your petitioners in the United States Circuit Court for the District of Maryland, charging that said Boyden air-brakes infringe the *first, second and fourth* claims of said Westinghouse patent, No. 360,070. Several years were spent in getting the case ready for trial, and finally it was argued before His Honor Judge Morris, at Baltimore, in November, 1894. Judge Morris held, in substance, that the Boyden brake does not employ the auxiliary, or emergency, valve of the Westinghouse patent, and, therefore, does not infringe the *first and fourth* claims thereof; but that the *second* claim of said patent is entitled to cover *functional equivalents*, or, in other words, results, and, in that view of the case, that this claim was infringed. Your petitioners appealed; and, on the 11th day of November, 1895, the United States Circuit Court of Appeals, sitting at Richmond, Va., affirmed Judge Morris' decision on the *first and fourth* claims, but reversed it on the *second*, holding, in substance, that patents are not entitled to cover *functional* equivalents, but only *mechanical* equivalents, and that the Boyden apparatus

contains no mechanical equivalent of Mr. Westinghouse's auxiliary, or emergency, valve. In obedience to the mandate of the Circuit Court of Appeals, Judge Morris dismissed the Bill of Complaint in the Court below. The complainants then applied for a writ of *certiorari* from this Court to the Circuit Court of Appeals, under Act of March 3, 1891, and it was granted, thus bringing the whole controversy before this Court for review.

As the result of Judge MORRIS' decision, your petitioners were under injunction from the 25th day of April, 1895, to the 16th day of December, 1895, and were thereby subjected to heavy loss, damage and injury to their business.

The pendency of this suit during the long period from the filing of the Bill of Complaint till the decision of the Circuit Court of Appeals—six years—was also very disastrous to your petitioners' business. The railroad companies throughout the country were warned by the complainants not to buy your petitioners' air-brakes, and the great majority of them did not dare to buy while the litigation was still undecided. The complainants thus succeeded in making the mere fact of a pending suit operate substantially with the same effect as an injunction. After the decision of the Circuit Court of Appeals, your petitioners were for the period of about two months relieved from this interference with their business; but since this Honorable Court has granted the writ of *certiorari*, renewing and continuing the litigation after it was believed to have been ended, your petitioners again find their business ruinously obstructed and substantially stopped, so that, although clear of Judge MORRIS, injunction, they practically might as well be under it.

To increase the timidity of the railroads and ensure the destruction of your petitioners' business, the Westinghouse Company has recently adopted the policy of bringing suits against the railroads, charging them, in one case, with infringing said patent, No. 360,070, by allowing a single freight car equipped with your petitioners' air-brakes to be hauled over their tracks, although the car in question belonged to some other railroad. And thus it has come to pass

that, although by the unanimous judgment of the Circuit Court of Appeals for the Fourth Circuit, your petitioners have as clear a right to put out their air-brake as the Westinghouse Company has to put out its own, yet they have been for the long period of six years, and now are, prevented from so doing, while their adversary has been, and still is, reaping the entire profits of this vast business, even to the extent of declaring dividends of 40 per cent. per annum on a capital stock of \$5,000,000. Justice and equity demand that this condition of affairs shall not be allowed to continue one day longer than is absolutely unavoidable. Your petitioners respectfully submit that on this ground alone the hearing in this case should be advanced.

2. But, we respectfully submit, there is another and still stronger reason why it should be advanced.

Unless advanced, a decision could hardly be reached before the end of the year 1897, if, indeed, so early as that. But if the decision of this Court be delayed till the last half of 1897, then, even though it be in our favor, we shall be practically robbed of the entire value of our patents and our large and valuable business interests will have been irreparably damaged and all its substantial profits handed over the Westinghouse Air-Brake Company. For, by the Act of 1893, 27 Stat. at Large, p. 531, chap. 196, entitled

"An Act to promote the safety of employees and travelers upon railroads by compelling common carriers engaged in interstate commerce to equip their cars with automatic couplers and continuous brakes and their locomotives with driving-wheel brakes, and for other purposes,"—

all railroads engaged in interstate commerce must be fully equipped with power brakes on or before the first day of January, 1898, or suffer a heavy penalty. All freight cars may be said to be engaged in interstate commerce, as they go from one road to another, and practically wander all over the country, even although the railroad which owns them may be a short line lying within a single State. It is, therefore, imperatively necessary for every railroad in the country to

fully equip its cars with air-brakes prior to January 1, 1898. In fact, the railroads have for a long time been, and now are, actively endeavoring to comply with the provisions of said Act. The effect of the Act is, therefore, to compel the railroads to spend about \$32,000,000 within the next two years in providing their freight cars with air-brakes; and the effect of your Honors' refusal to advance this cause would be to give that entire business to the Westinghouse Company; and if your Honors' decision should finally be rendered in our favor, as we confidently expect it will be, it will give us the shadow and not the substance—the mine, after all the ore has been extracted by our adversaries.

Even if this condition of things had come about by natural causes, it would, we respectfully submit, appeal strongly to your Honors to advance and expedite the hearing of this cause; but when we consider that it is a situation forced upon us directly by the intervention of the legislative department of the Government, it would seem that the judicial department ought to give us what relief it can by advancing the hearing of our cause, to save us from a disaster which Congress certainly did not contemplate when it passed the act. The government has given us our patents; the Circuit Court of Appeals, whose decision in patent cases is ordinarily final, has unanimously declared our right to the free use of them; Congress has intervened to render that right practically worthless unless it can be exercised promptly; and this Honorable Court, by granting the writ of *certiorari*, has cut us off from the present enjoyment of that right, and jeopardized our chances of ever enjoying it, even though your Honors' decision should ultimately be in our favor. The only way in which relief can now come is by a speedy hearing and adjudication of the merits of our cause. If left to take the usual course, the injury to us will be irreparable.

3. The case is one of great public importance and interest; otherwise, under the repeated decisions of this Court, the writ of *certiorari* would not have been granted. The same reason of public importance which led to the

grant of the writ of certiorari by this Court leads equally to the advancement of the hearing; and, when supplemented as it is by the other potent considerations hereinabove referred to, and by the fact that justice, in this case of great public importance, will be absolutely denied unless a speedy trial can be had, it would seem to appeal with irresistible force.

The public importance of the case arises not merely from the great sum of money at stake, but from other facts as well. The use of air-brakes, by enabling the speed of freight cars to be doubled with safety, in effect nearly doubles the entire traffic capacity of the railroads of this country. They are also life-saving and property-saving devices of such public value that, as we have seen, Congress has taken the unusual course of making their immediate use imperative. The importance of such use on all the railroads of the country having thus been authoritatively declared by the National legislature, it is of great public importance that the Act of Congress should be faithfully complied with. But there are over 1,000,000 freight cars in use in this country, of which, during the eight years since these quick-action brakes came upon the market, less than 400,000 have been equipped therewith,—leaving over 600,000, and perhaps more than 700,000, to be equipped before January 1, 1898,—and it is doubtful if the Westinghouse Company, with all its facilities, can supply this demand within the next two years. It is, therefore, highly important to the public, and to the execution of this law, that your petitioners shall have their rights adjudicated at the earliest possible moment, to the end that, if found to be lawfully entitled to manufacture and sell the Boyden brake, as they believe will be the fact, they may be dismissed from this litigation in season to render the railroads effective aid in securing the required brake equipment within the time limited by Congress.

But even if the Westinghouse Company should be able within the next two years to furnish all the air-brakes necessary to fulfill the requirements of the Act of Congress,

still it is important to the public interests that there shall be a wholesome competition in the business, as will be the case if your petitioners are free to enter the field. Otherwise, the railroads, carriers of the United States mail, confronted on the one hand by an Act of Congress which compels them to provide these requirements by January 1st, 1898, and on the other hand by a company which is allowed to exercise the exclusive privilege of furnishing said equipments at prices controlled only by themselves, will be liable to be ground between the upper and lower millstones of corporate greed. The dividends of the Westinghouse Company show that these brakes can be made and sold at a handsome profit at prices far below those heretofore exacted, and it is obviously for the public interest that competition in this important field of industry should not be kept suppressed, nor an absolute monopoly continued any longer than is imperatively necessary.

4. Cases involving patents of great value, where, by reason of litigation, the patentee is practically excluded from the enjoyment of his invention for years after the grant of his patent, as in the present instance, present strong claims for an immediate adjudication, and for an advancement upon the calendar if necessary to that end. In the judgment of Congress, a seventeen-year monopoly is the proper reward for a meritorious inventor who has contributed to the promotion of the useful arts. Every day's delay in the final adjudication of such a case cuts off a day from the life of the inventor's protection. Your petitioners' patents have already been shortened to about thirteen years; and, if your Honors should not advance this hearing, they will be further shortened to about eleven years, commencing after the most important profits of the business will have been absorbed by the adversary who has caused the loss of one-third of the life of our patents.

5. Your petitioners stand before this Honorable Court with the legal presumption that they have the right to manufacture, sell and use the Boyden quick-action air-brake—a presumption arising out of the unanimous decision

of the Circuit Court of Appeals upon that question. Your petitioners' right to produce and vend these brakes is founded upon the fact that the Boyden brake is an invention wholly different from that of Mr Westinghouse, and in no legal or equitable sense an infringement of his patent. They do not question the validity of Mr. Westinghouse's patent, nor deny his right to the exclusive use of his invention till the end of the term. Their position is, that his patent must be construed as covering only his invention, and that it does not cover the production of the same result by other and different means which are not the mechanical equivalents of his means. Their interpretation of his patent is precisely the same as that adopted by His Honor, Judge LACOMBE, and by the Circuit Court of Appeals for the Second Circuit, in the case against the New York Air-Brake Company, referred to in the complainants' papers on the application for a *certiorari* in this case. In this construction of the Westinghouse patent, the Circuit Court of Appeals for the Fourth Circuit agreed with your petitioners and with Judge LACOMBE and the New York Circuit Court of Appeals, and directed the complainants' bill to be dismissed with costs. Your petitioners have never understood, and do not now understand, the decision of the Circuit Court of Appeals in this case as going beyond the question of infringement. It is true that there is, in the *opinion* of that Court, one expression intimating that the broad terms of the second claim are "fatal," which expression, read without reference to other parts of the opinion, might lead to the conclusion that the Court was disposed to hold said claim invalid; but your petitioners and their counsel have always understood that expression to mean "fatal, unless limited, by construction, to the invention made by Mr. Westinghouse," and in this view they are borne out by the fact that, in another part of the opinion, the Court discussed the effect of the words in the claim, "substantially as described," and held that they required the patent to be limited as above stated.

In the application for a *certiorari*, said expression, however, was cunningly removed from its context and held up

before this Court, apart from the rest of the opinion, as showing that there was a direct conflict between the judgments of the two Circuit Courts of Appeal, although counsel well knew that the validity of the Westinghouse patent was openly admitted by your petitioners and their counsel in their arguments and briefs used on the trial of the case at Richmond. How far this subtle proceeding may have influenced your Honors to grant the writ of *certiorari*, we do not know; but if it had any influence at all in that direction, an additional reason is thereby furnished for a speedy adjudication of the case, in order that the complainants may not profit by their own wrong, by which they have succeeded in again tying up your petitioners' business for an indefinite time.

6. The hearing and adjudication of the case will not impose upon your Honors a long and arduous labor. The points to be decided are but two in number, viz:

(a) Is the Westinghouse patent to be construed as limited to Mr. Westinghouse's auxiliary or emergency valve, as held by the Circuit Court in New York and the Circuit Courts of Appeals of the Second and Fourth Circuits; or, on the other hand, is it to be construed as covering a *result*, and as infringed by a structure which does not contain such auxiliary or emergency valve, as held by Judge Morris in Baltimore?

Your Honors have already decided the law of this question too many times to need much further consideration of it now.

(b) Is the Boyden combination the same in mode of operation and mechanical means as the Westinghouse combination; or, on the other hand, is it a new and different invention, accomplishing its result by other means and a different mode of operation, as unanimously held by the Circuit Court of Appeals for the Fourth Circuit, and substantially conceded even by Judge Morris in his opinion?

The solution of this question needs merely a thorough understanding of the two structures and of the Westinghouse patent.

No question of prior invention, anticipation, or public use, is raised, but simply the question of infringement. The case, therefore, involves no unusual amount of labor on your Honors' part. It can be heard and decided before the end of this term, without seriously interfering with the other business of the Court. To postpone it to October would use up about one-third of the time available to your petitioners under the Act of Congress above referred to.

Your petitioners are fully sensible of the great labor devolved upon this Court in the ordinary transaction of its business; and but for the turn that affairs have taken, and the pressure of the Act of Congress, which threaten to destroy their important and valuable interests, they would not ask your Honors to intervene in their behalf, but would await the regular call of the calendar, although thereby losing two years of the life of their patent protection and their business. Under existing circumstances, however, they have no recourse but to apply to your Honors for relief, which they feel should be awarded both on the ground of the public interests and for the prevention of the grievous wrongs which your petitioners are now suffering. It will be seen that, in the language of Rule 26, paragraph 7, the "circumstances" of your petitioners' case are "special and peculiar," and such as are never likely to arise again in any other case; so that, by granting this relief, in view of the peculiar effect of the Act of Congress referred to, no precedent will be established that will be liable to embarrass this Court in the future.

BOYDEN POWER BRAKE COMPANY. *

By G. A. BOYDEN, *President*.
C. B. MANN, *Secretary*.
W. WHITRIDGE, *Treasurer*.

And BOYDEN BRAKE COMPANY,

By G. A. BOYDEN, *President*.

LYSANDER HILL,

Counsel for Petitioners.

STATE OF MARYLAND, }
CITY OF BALTIMORE, } ss.

George A. Boyden, having been duly sworn, deposes and says: That he is one of the above-named petitioners; that he has read said petition, by him subscribed, and understands the contents thereof; and that the statements of facts therein contained are true to the best of his information and belief.

G. A. BOYDEN.

Subscribed and sworn to before me this 14th day of March, A. D. 1896.

GEO. E. TAYLOR,
Notary Public.

Subsequently, to wit, on November 16, 1896, this honorable Court made an order restoring the said causes to the calendar and directing a reargument thereof.

The effect of said order of November 16, 1896, is to restore said causes to their original position on the calendar as though they had not been advanced, unless a new order shall be made in pursuance of this motion.

The same reason for advancement and early hearing of said causes exist now that existed at the time of the previous motion to advance; and as said reasons are fully set forth in the petition of The Boyden Power Brake Co. then filed, a copy of said petition is hereto annexed.

An additional reason for an early re-assignment of said causes exists in the fact that while the technical matters of mechanics involved in the issues are fresh in the mind of the Court, it would perhaps avoid the necessity of re-arguing such matters in detail, and thereby lessen the labor of the Court, if the causes are again heard at an early date.

Since the making of the order of November 16, 1896, restoring the causes to the calendar, notice of this motion, to be made on November 30, 1896, has been given to counsel of record for the Westinghouse Air-Brake Company, as also notice that January 4, 1897, would be suggested to this honorable Court as an appropriate and convenient date to be assigned for the hearing of said causes, if this motion to advance the same be allowed.

LYSANDER HILL,
HECTOR T. FENTON,
MELVILLE CHURCH,

Of Counsel for Boyden Brake Co.

November 30, 1896.

SUPREME COURT OF THE UNITED STATES.

AIR-BRAKE CASES.

Memorandum on Behalf of the Boyden Company re Petition for Rehearing.

It is not our purpose to trouble the Court with an argument in reply to the petition for rehearing, and brief in support thereof, which are occupied with criticisms of the decision of the Court reached after three exhaustive arguments of the case. We deem it proper, however, to call attention to a matter of vital concern to defendants.

When the case came to the Court in the spring of 1896, the Court recognized that defendants were entitled to a prompt adjudication (see motion to advance). The particular reason was that Congress had fixed a short limit of time within which the railroads of the country were required to equip their freight cars with air-brakes. That time (though it has been extended by Congress) has nearly expired, and further prolongation of the uncertainty created by this litigation would be as advantageous to complainant, and as injurious to defendants, as a decision in favor of the former. Railroads will not equip their cars with brakes which, by a subsequent order of the Court, they may be required to strip off. Thus,

for nearly nine years, during which defendants have been pursued in this litigation, complainant has enjoyed a practical monopoly, while defendants have been deprived of all use of their patented devices.

On page 16 of complainant's brief, filed with the petition, is the statement that in 1896 there were over four hundred thousand Westinghouse brakes (which, at forty dollars each, the standard price, represents an income of over sixteen million dollars), while of defendant's brake there were less than five hundred.

A prolongation of the conditions to which this result has been due would be of incalculable injury to defendants. We therefore most earnestly beg the Court, if it be possible, that the petition for rehearing be disposed of before the adjournment of the Court.

Very respectfully,

ANTHONY POLLOK,
PHILIP MAURO,
Of Counsel for Defendants.

BLEED. THROUGH POOR COPY

99 & 116.

IN THE
Supreme Court of the United States
OCTOBER TERM, 1897.

Nos. 99 and 116.

WESTINGHOUSE AIR BRAKE COMPANY ET AL.
vs.
BOYDEN BRAKE COMPANY ET AL.

SUGGESTION OF COUNSEL AS TO RE-ARGUMENT.

*To the Honorable the Chief Justice and Associate Justices of the
Supreme Court of the United States:*

The parties to the above-entitled cause, in view of the fact that the said cause has twice been argued before this honorable Court, respectfully suggest that it may conduce to the convenience of the Court, as well as to that of the parties to the cause and their respective counsel, if to the Court it seems proper, that the Court would indicate, with as much particularity as is practicable, the points in said cause upon which the Court is desirous of hearing counsel in the re-argument that has been ordered.

The undersigned therefore respectfully unite in this sug-

gestion, and ask the Court to take such action hereon as to it may seem proper.

And as in duty.

BARTON & WILMER,

Of Counsel for Boyden Brake Co.

GEORGE H. CHRISTY,

FREDERIC H. BETTS,

Of Counsel for Westinghouse Air Brake Co.

MELVILLE CHURCH,

Of Counsel for Boyden Power Brake Co.

[Endorsed:] Case No. 16,137. Supreme Court U. S., October term, 1897. Term Nos., 99 and 116. Boyden Power Brake Co. *et al.*, app'ts, *vs.* Geo. Westinghouse, Jr., *et al.* Suggestion that Court indicate points on re-argument. Filed January 17, 1898.

WESTINGHOUSE *v.* BOYDEN POWER BRAKE
COMPANY.

BOYDEN POWER BRAKE COMPANY *v.* WEST-
INGHOUSE.

CERTIORARI TO THE CIRCUIT COURT OF APPEALS FOR THE FOURTH
CIRCUIT.

Nos. 116, 99. Argued March 10, 11, 1898. — Decided May 9, 1898.

The Boyden device for a fluid-pressure break is not an infringement of patent No. 360,070 issued to George Westinghouse, Jr., March 29, 1887, for a fluid-pressure automatic-brake mechanism.

This was a writ of certiorari to review a decree of the Circuit Court of Appeals, reversing a decree of the Circuit Court for the District of Maryland, which had sustained, in part, a bill filed by Westinghouse against the Boyden Power Brake Company for the infringement of patent No. 360,070, and from which decree both parties had taken an appeal to the Circuit Court of Appeals.

The patent in suit, which was issued March 29, 1887, to George Westinghouse, Jr., is for a fluid-pressure automatic-brake mechanism, the object of which is said in the speci-

Statement of the Case.

fication to be "to enable the application of brake-shoes to car-wheels by fluid pressure to be effected with greater rapidity and effectiveness than heretofore, more particularly in trains of considerable length, as well as to economize compressed air in the operation of braking, by utilizing in the brake-cylinders the greater portion of the volume of air which in former practice was directly discharged into the atmosphere."

"To this end my invention, generally stated, consists in a novel combination of a brake-pipe, an auxiliary reservoir, a brake-cylinder and a 'triple-valve' device, governing, primarily, communication between the auxiliary reservoir and the brake-cylinder, and, secondarily, communication directly from the brake-pipe to the brake-cylinder."

There follows here a description of the Westinghouse automatic brake as theretofore used, its mode of operation, and the defects or insufficiencies which attended its application to long trains, in the following language :

"In the application of the Westinghouse automatic brake as heretofore and at present commonly in use, each car is provided with a main air-pipe, an auxiliary reservoir, a brake-cylinder and a triple-valve, the triple-valve having three connections, to wit, one to the main air-brake pipe, one to the auxiliary reservoir and one to the brake-cylinder. The main air-pipe has a stop-cock at or near each of its ends, to be opened or closed as required, and is fitted with flexible connections and couplings for connecting the pipes from car to car of a train, so as to form a continuous line for the transmission of compressed air from a main reservoir supplied by an air-pump on the engine. When the brakes are off or released, but in readiness for action upon the wheels of the train, the air which fills the main reservoir and main air-pipes has a pressure of from sixty-five to seventy-five pounds to the square inch, and by reason of the connections referred to the same pressure is exerted in the casings of the triple-valves on both sides of their pistons and in the auxiliary reservoirs connected therewith. At the same time passages called 'release-ports' are open from the brake-cylinders to the atmosphere. When it is desired to apply the brakes, air is

Statement of the Case.

allowed to escape from the main air-pipes through the engineer's valve, thereby reducing the pressure in the main air-pipes, whereupon the then higher pressure in the auxiliary reservoirs moves the pistons of the triple-valves, so as to first close the passages from the triple-valves to the brake-pipe and at the same time close the release-ports of all the brake-cylinders, and then open the passages from the auxiliary reservoirs to the brake-cylinders, the pistons of which are forced out by the compressed air thereby admitted to the brake-cylinders, applying the brakes by means of suitable levers and connections, all of which mechanism is fully shown in various letters patent granted to me."

"The application of the brakes with their full force has heretofore required a discharge of air from the main pipe sufficient to reduce the pressure in said pipe below that remaining in the auxiliary reservoir after the brakes have been fully applied, and it has been found that, while the brakes are sufficiently quick in action on comparatively short trains, their action on long trains of from thirty to fifty cars, which are common in freight service under present practice, is in a measure slow, particularly by reason of the fact that all the air required to be discharged from the main pipe to set the brakes must travel from the rear of the train to a single discharge opening on the engine. This discharge of air at the engine has not only involved a serious loss of time in braking, but also a waste of air. Under my present invention a quicker and more efficient action of the brakes is obtained, and air which has been heretofore wasted in the application of the brakes is almost wholly utilized to act upon the brake-pistons."

After a detailed description of the invention, an important feature of which is a triple-valve, (hereinafter more fully explained in the opinion,) with references to the accompanying drawings, the specification proceeds to state that, "so far as the performance of its preliminary function in ordinary braking is concerned—that is to say, effecting the closure of communication between the main-air pipe and the auxiliary reservoir, and the opening of communication between the aux-

Statement of the Case.

iliary reservoir and the brake-cylinder in applying the brakes, and the reverse operations in releasing the brakes—the triple-valve 10 accords substantially with that set forth in letters patent of the United States No. 220,556, granted and issued to me October 14, 1879, and is not, therefore, saving as to the structural features by which it performs the further function of effecting the direct admission of air from the main air-pipe to the brake-cylinder, as presently to be described, claimed as of my present invention. Certain of its elements devised and employed by me prior thereto will, however, be herein specified, in order to render its construction and operative relation to other members of the brake mechanism fully intelligible.”

After a further reference to the drawings he again states that “so far as hereinbefore described, the triple-valve accords in all substantial particulars with and is adapted to operate similarly to those of my letters patent Nos. 168,359, 172,064 and 220,556, and, in order that it may perform the further functions requisite in the practice of my present invention, it is provided with certain additional members, which will now be described.” These additional members, which are said to be for the purpose of effecting the admission of air directly from the main air-pipe to the brake-cylinder when it is desired to apply the brakes with great rapidity and full force, consist of (1) a passageway through which air can be admitted directly from the main air (or train) pipe to the brake-cylinder, without passing through the auxiliary reservoir; and, (2) an auxiliary valve in connection with such passage, that, when the triple-valve piston makes a short or preliminary movement, the passageway direct from the train-pipe to brake-cylinder, controlled by said valve, will not be opened, while, in the event of a long or full movement of the piston, or “further traverse,” as it is called, such direct passageway will be thrown wide open to the admission of train-pipe air, and the brake-cylinder will be rapidly filled thereby.

After describing the auxiliary sliding valve 41 and its connections, as well as the operation of the device in ordinary (non-emergency) cases of checking the speed of or stopping trains, already fully provided for in previous patents, he pro-

Statement of the Case.

ceeds to state its operation in cases of emergency which the patent was specially designed to cover, as follows:

"In the event, however, of its becoming necessary to apply the brakes with great rapidity and with their greatest available force, the engineer, by means of the valve at his command, instantly discharges sufficient air from the front end of the main air-pipe to effect a sudden reduction of pressure of about twenty pounds per square inch therein, whereupon the piston 12 of the triple-valve is forced to the extreme limit of its stroke in the direction of the drain-cup 19, carrying with it the stem 36 and auxiliary slide-valve 41, which instantly uncovers the port 42 and discharges air from the main air-pipe through the opening of the check-valve 49 and the passages 46 and 48 to the brake-cylinder, and, each car being provided with one of these devices, it will be seen that they are successively moved with great rapidity, there being practically on a train of fifty cars fifty openings for discharging compressed air from the main pipe instead of the single opening heretofore commonly used. Not only is there a passage of considerable size opened from the brake-pipe on each car, whereby the pressure is more quickly reduced, but the air so discharged is utilized in the performance of preliminary work, it being found in practice that the air so taken from the pipe will exert a pressure of about twenty-five pounds in the brake-cylinders. When the piston 12 arrives at the extremity of its stroke as above specified, the supplemental port 35 of the slide-valve 14 is brought into communication with the port 33 and passages 22 and 16, which serves to discharge the reservoir-pressure into the brake-cylinder, thereby augmenting the pressure already exerted in the brake-cylinder by the air admitted from the main air-pipe. Upon the reduction of the pressure in the main air-pipe below that in the brake-cylinders, as by the breaking in two of the train, the check-valve 49 closes communication between the passages 46 and 18, thereby preventing the return of the air from the brake-cylinder to the main air-pipe. The feed-opening for the admission of air from the auxiliary reservoir to the brake-cylinder is purposely made of comparatively small diameter, it having been determined

Statement of the Case.

by experiment that the initial application of the brakes should not be made with maximum force, and this opening may be made of such size as to apply the brakes exactly in accord with the requirements of the most efficient work."

"In using the terms 'triple-valve' and 'triple-valve device' I refer to a valve device, however specifically constructed, having a connection with the main air or brake-pipe, another with an auxiliary reservoir or chamber for the storage of power, and another with a brake-cylinder or its equivalent for the utilization of the stored power, and with a release or discharge passage for releasing the operative power from the brake-cylinder, whether the valves governing these passages or connections are arranged in one or more cases and are moved by a piston or its equivalent or by a series of pistons or their equivalents, there being numerous examples in the art of constructions varying materially in appearance whereby these functions are performed, both in plenum and vacuum brake mechanisms."

The above drawings are somewhat clearer than those annexed to the patent, and exhibit the triple-valve and its connections in three positions, viz., No. 13, Released or "Brakes Off;" No. 14, Ordinary Service Application, and No. 16, "Quick Action" Position.

The only claims of the patent alleged to have been infringed are the first, second and fourth, which read as follows:

"1. In a brake mechanism, the combination of a main air-

Statement of the Case.

pipe, an auxiliary reservoir, a brake-cylinder, a triple-valve and an auxiliary-valve device, actuated by the piston of the triple-valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake cylinder, substantially as set forth."

"2. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, and a triple-valve having a piston whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth."

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, and an auxiliary valve actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, substantially as set forth."

The joint and several answer of the Boyden Brake Company and the individual defendants admitted that such company was engaged in manufacturing and selling a fluid-pressure brake, but denied that the same was an infringement upon complainants' patent, and also denied that Westinghouse was the original inventor of the mechanism covered by the patent, and alleged that an apparatus, substantially identical in character, had been previously granted Westinghouse, March 5, 1872, (No. 124,404,) and that a like apparatus was previously described in the following patents issued to Westinghouse, viz.: No. 138,827, May 13, 1873; No. 144,006, October 28, 1873; No. 168,359, October 5, 1875; No. 172,064, January 11, 1876; No. 220,556, October 14, 1879, and also in three patents to other parties, not necessary here to be specifically mentioned.

The answer further denied any infringement of the first, fourth and fifth claims of the patent sued upon, (No. 360,070.) and, with respect to the second claim, averred the same to be

Counsel for Westinghouse.

invalid because the combination of parts therein named is inoperative to perform and incapable of performing the function set forth in said claim ; and that, if the said claim be considered merely as the combination of parts therein set forth, and without reference to the function described as performed by it, it is invalid for the reason that the same combination of parts is shown in most of the prior patents above cited, and has been publicly used by the complainants for a long time prior to the date of the said letters patent No. 360,070.

The answer further averred the claim to be uncertain and ambiguous, and if the functions recited by it are construed as amplifying the description of the combination to distinguish this combination from that shown in the prior patents, "then the defendants say that the said claim is anticipated by the prior letters patent issued to George A. Boyden on June 26, 1883, for the reason that air-brake valves made in accordance with the last mentioned patent embody the same combination of parts, and will perform the same functions, and operate in substantially the same manner as stated in said second claim."

Upon a hearing in the Circuit Court upon the pleadings and proofs, that court was of opinion that the second claim was valid, and had been infringed, but that defendants had not infringed claims one and four, and as to those the bill was dismissed. 66 Fed. Rep. 997. From the decree entered in pursuance of this opinion both parties appealed to the Court of Appeals for the Fourth Circuit, which affirmed the action of the Circuit Court with respect to the first and fourth claims, but reversed it with respect to the second claim, and dismissed the bill. 25 U. S. App. 475. Whereupon complainants applied for and were granted a writ of certiorari.

Full copies of the principal Westinghouse patents are printed in *Westinghouse Brake Co. v. N. Y. Brake Co.*, 26 U. S. App. 248, and of the Boyden patents in the report of this case in 25 U. S. App. 475.

Mr. George H. Christy and *Mr. Frederic H. Betts* for Westinghouse. *Mr. J. Snowden Bell* and *Mr. Bernard Carter* were on their brief.

Opinion of the Court.

Mr. Philip Mauro and *Mr. Lysander Hill* for the Boyden Power Brake Company. *Mr. Hector T. Fenton*, *Mr. Melville Church* and *Mr. Anthony Pollok* were on their brief.

MR. JUSTICE BROWN, after stating the case, delivered the opinion of the court.

The history of arresting the speed of railway trains by the application of compressed air is one to which the records of the Patent Office bear frequent witness, of a gradual progress from rude and imperfect beginnings, step by step, to a final consummation, which, in respect to this invention, had not been reached when the patent in suit was taken out, and which, it is quite possible, has not been reached to this day. It is not disputed that the most important steps in this direction have been taken by Westinghouse himself.

The original substitution of the air-brake for the old hand-brake was itself almost a revolution, but the main difficulty seems to have arisen in the subsequent extension of that system to long trains of freight cars, in securing a simultaneous application of brakes to each of perhaps forty or fifty cars in such a train, and finally in bringing about the instantaneous as well as simultaneous application of such brakes in cases of emergency, when the speediest possible stoppage of the train is desired to avoid a catastrophe.

Patent No. 88,929, issued April 13, 1869, appears to have been the earliest of the Westinghouse series. This brake, known as the *straight-air brake*, consisted of an air-compressing pump, operated by steam from the locomotive boiler, by which air was compressed into a reservoir, located under the locomotive, to a pressure of about eighty pounds to the square inch. This reservoir, being still in use, is now known as the main reservoir. From this reservoir an air-pipe, usually called the train-pipe, led into the cab, where the supply of air was regulated by an "engineer's valve," thence down and back under the tender and cars, being united between the cars by a flexible hose with metal couplings, rendering the train-pipe continuous. These couplings were automatically

VOL. CLXX—35

Opinion of the Court.

detachable; that is, while they kept their grip upon each other under the ordinary strains incident to the running of the train, they would readily pull apart under unusual strains, as when the car coupling broke and the train pulled in two.

From the train-pipe of each car, a branch pipe connected with the forward end of a cylinder, called the "brake-cylinder," which contained a piston, the stem of which was connected with the brake levers of the car. This piston was moved and the brakes applied, by means of compressed air admitted through the train-pipe and its branches, into the forward end of the brake-cylinder. When the brakes were to be applied, the engineer opened his valve, admitted the compressed air into the train-pipes and brake-cylinders, whereby the levers were operated and the brakes applied. To release the brakes, he reversed the valve, whereby the compressed air escaped from the brake-cylinders, flowed forward along the train-pipe to the escape port of the engineer's valve, thence into the atmosphere. Upon the release of the compressed air, the pistons of the brake-cylinders were forced forward again by means of springs, and the brake-shoes removed from the wheels. By means of this apparatus, the train might be wholly stopped or slowed down by a full or partial application of the brakes. As between a full stop and a partial stop, or slow speed, there was only a question of the amount of air to be released from the main reservoir. The validity of this patent was sustained by the Circuit Court for the Northern District of Ohio, Mr. Justice Swayne and Judge Welker sitting, in *Westinghouse v. The Air Brake Company*, 9 Official Gazette, 538. The court said, in its opinion, that while Westinghouse was not the first to conceive the idea of operating railway brakes by air pressure, such fact did not detract at all from his merits or rights as a successful inventor; that the new elements introduced by him "fully substantiated his pretensions as an original and meritorious inventor, and entitled him as such to the amplest protection of the law;" and that it appeared from the record and briefs that he was the first to put an air-brake into successful actual use.

While the application of this brake to short trains was

Opinion of the Court.

reasonably successful, the time required for the air to pass from the locomotive to the rear cars of a long train (about one second per car) rendered it impossible to stop the train with the requisite celerity, since in a train of ten cars it would be ten seconds before the brakes could be applied to the rear car, and to a freight train of fifty cars nearly a minute. While the speed of the foremost car would be checked at once, those in the rear would proceed at unabated speed, and in their sudden contact with the forward cars would produce such shocks as to often cause damage. As a train moving at the rate of fifty miles an hour makes over seventy feet per second, a train of fifty cars would run half a mile before the brakes could be applied to the rear car. So, too, if the rear end of the train became detached from the forward end by the rupture of the train-pipe or couplings, the brakes could not be applied at all, since the compressed air admitted to the train-pipe by opening the engineer's valve would escape into the atmosphere without operating the brakes, or if the brakes were already applied, they would be instantly released when such rupture occurred.

The first step taken toward the removal of these defects resulted in what is known as "the *automatic brake*," described first in patent No. 124,404 in a crude form, and, after several improvements, finally culminating in patent No. 220,556 of 1880. The salient features of this brake were an auxiliary reservoir beneath each car for the reception and storage of compressed air from the main reservoir, and a triple-valve, so called, automatically controlling the flow of compressed air in three directions, by opening and closing, at the proper times, three ports or valve openings, viz.: 1. A port or valve known as the "feeding-in valve" from the train-pipe to the auxiliary reservoir, allowing the auxiliary reservoir to fill so as to be ready when the brakes were applied; 2. A port or valve from the auxiliary reservoir to the brake-cylinder, which allowed a flow of compressed air to apply the brakes, and was called the "main valve;" 3. A port or valve from the brake-cylinder to the open air, denominated the "release-valve," to be opened when it was desired to release the brakes.

Opinion of the Court.

The operation of these valves was as follows: Before the train starts, compressed air from the main reservoir is permitted to flow back through the train-pipe, and through valve No. 1, for the purpose of charging the auxiliary reservoir beneath each car with a full working pressure of air. When it is desired to apply the brakes, the engineer's valve is shifted, and the air in the train-pipe is allowed to escape into the atmosphere at the engine. Thereupon the compressed air in the auxiliary reservoir closes valve No. 1, leading to the train-pipe, and opens the main valve No. 2, from the auxiliary reservoir to the brake-cylinder, whereby the piston of that cylinder operates upon the brake-levers and applies the brakes. By this use of the auxiliary reservoirs a practically simultaneous application of the brakes is secured for each car. This application of the brakes is secured, not by direct application of compressed air from the engine through the train-pipe, but by a reverse action, whereby the air is allowed to escape from the train-pipe toward the engine, the pressure being applied by the air escaping from the auxiliary reservoirs. It also results that, if a train should pull in two, or a car become detached, the same escape of air occurs, the same action takes place automatically at the broken part, and the same result follows by the escape of the compressed air through the separated couplings. When it is desired to release the brakes, the engineer's valve is again shifted, and the compressed air not only opens valve No. 1 from the train-pipe to the auxiliary reservoir, but valve No. 3 from the brake-cylinder to the open air, which allows the air from the brake-cylinder to escape and thus release the brake.

From this description it will be seen that the action of the automatic brake was, in fact, the converse of that of the straight air-brake, and that the result was to obviate the most serious defects which had attended the employment of the former.

This automatic brake appears, in its perfected form, in patent No. 220,556, although this patent was but the culmination of a series of experiments, each successive step in which appears in the prior patents. Thus in patent No. 124,404, (1872),

Opinion of the Court.

is introduced the auxiliary reservoir beneath each car in connection with a double line of brake-pipes and a single cock with suitable ports for charging the reservoir and for operating the brakes — a device which was obviously the foundation of the triple-valve which first made its appearance in patent No. 141,685, (1873,) in which the main valve, which admitted air from the auxiliary reservoir to the brake-cylinder, was of the poppet form; and as a poppet-valve can govern only one port, separate valves had to be provided for feeding in the air from the train-pipe to the auxiliary reservoir, and for discharging the air from the brake-cylinder to release the brakes. In subsequent patents, No. 144,006, (1873,) and No. 163,242, (issued in 1875 to C. H. Perkins and assigned to Westinghouse,) Mr. Westinghouse improved upon his prior devices by substituting a sliding-piston valve for the poppet form of main valve previously used by him. This enabled the piston to perform the feed-valve function of admitting air from the train-pipe to the auxiliary reservoir; the main-valve function of admitting air from the auxiliary reservoir to the brake-cylinder to apply the brakes, and the release-valve function of discharging the air from the cylinder to release the brakes. In patent No. 168,359, (1875,) a piston actuating a slide-valve was substituted for the piston-valve, and, after a series of experiments, which did not seem to have been successful, he introduced into patent No. 217,838 the idea of venting the train-pipe, not only at the locomotive, but also under each car, in order to quicken the application of the brakes. Prior to this time, "when the engineer desired to apply his brakes with full force he operated the valve at the engine and opened the port wide, letting the compressed air out of the train-pipe at the locomotive, then its only vent. The air, as before said, had to travel from the rear cars along the cars forward to the engine before it could lessen the pressure of the train-pipe air, . . . and before the brake-cylinder could be operated with air from the auxiliary reservoirs. In a train of fifty cars it would have to travel nearly half a mile to get out at the engine." He embodied in patent No. 220,556, (1879,) the most complete form of the automatic brake, and as stated by the

Opinion of the Court.

court below, "the ordinary work of braking was performed by a partial traverse of its chamber by the triple-valve piston, graduated according to the purpose desired, at the will of the engineer, and emergency work was done by an extreme traverse of the piston to the end of its chamber."

While the automatic brake had thus obviated the most important defects of the old or straight air-brake, and come into general use upon passenger trains throughout the country, it was found, in practice upon long freight trains, that the air from the auxiliary reservoirs did not act with sufficient promptness upon the brakes of the rear cars, where a particularly speedy action was required, and that it would be necessary to devise some other means for cases of special emergency. In the business of transporting freight over long distances, the tendency has been in the direction of increasing the load by using stronger and heavier cars and larger locomotives. Upon a long train of this kind, composed of thirty to fifty cars, a demand was made for quicker action in cases of emergency than had yet been contemplated, although for ordinary work, such as checking the speed of a train while running, holding it at a slow speed on a down grade, and also for making the ordinary station stops, the automatic brake was still sufficient, and produced satisfactory results even in the equipment of long and heavy trains. But however effective for ordinary purposes, the automatic brake did not sufficiently provide for certain emergencies, requiring prompt action, and, therefore, failed in a single important particular.

Upon examination of these defects it was found that they could only be remedied by securing, (1) in cases of emergency, a more abundant discharge of compressed air into the brake-cylinder; and (2) an escape of air near to each triple-valve without requiring the escaping air to travel all the way back to the engine. The latter device having been already embodied in patent No. 217,838, these features Mr. Westinghouse introduced into the patent in suit, by which a passage was opened directly from the train-pipe filled from the main reservoir on the engine, to the brake-cylinder through which, in cases of emergency, the train-pipe air, instead of being dis-

Opinion of the Court.

charged into the atmosphere, could pour directly from the train-pipe into the brake-cylinder. This operation resulted in charging the brake-cylinder and applying the brakes more quickly than before, and also, by reason of the fact that the filling of the brake-cylinder from the train-pipe on one car made what was, in effect, a local vent for the release of pressure sufficient to operate the valve on the next car behind, each successive valve operated more quickly than when a diminution of pressure was caused by an escape of air only at the locomotive. The direct passage of the air from the train-pipe to the brake-cylinder was effected by a valve (41), colored red in the above diagrams, which is never opened except in cases of emergency. In ordinary cases, when the brakes are desired to be applied, sufficient air is released from the train-pipe to open the passage from the auxiliary reservoir to the brake-cylinder by what is called a preliminary traverse of the piston (12), but when a quick action is required sufficient air is drawn from the train-pipe, not only to open this passage, but by a further traverse of the piston, to shove valve 41 off its port, and introduce air directly from the train-pipe to the brake-cylinder, as shown in the following drawings.

In the foregoing skeleton drawings, from which all details of construction, and all figures of reference, not necessary for a clear understanding of the structure, are omitted, the

Opinion of the Court.

essential parts are colored, so that their changes of position in the different stages of action can be easily followed.

The access of train-pipe air is shown located at the right end of the structure, instead of the left, (as in the patent drawings,) simply for greater clearness. Its course from the train-pipe to the auxiliary cylinder is through the small port above the upper arm of the piston 12.

The "main valve" of the triple is *black*. Its office is to admit auxiliary reservoir air to brake-cylinder.

The "quick-action" valve is colored *red*. Its office is to admit *train-pipe air* to brake-cylinder.

The release port is colored *green*. Its office is to discharge air from brake-cylinder, in releasing the brakes.

There is also shown in *yellow* what is known as the graduating valve, the function of which will be hereafter explained. As at present used, the triple-valve is in reality a quadruple-valve.

The flow or movement of air, in the several positions of the structure is also shown by colored lines and arrows, viz.:

Air released from brake-cylinder to open air by *green* arrow.

Air flowing from auxiliary reservoir to brake-cylinder, in "service" application of the brakes, by *red* line. And air flowing from train-pipe to brake-cylinder in "quick-action" application, by *blue* line.

This patent, although it introduced a novel feature into the art, does not seem to have been entirely successful in its practical operation, since in October of the same year an improvement was patented, No. 376,837, with the object of still further increasing the rapidity of action. As observed by the District Judge in this connection, "the success of this improved device, No. 376,837, has demonstrated that the invention, by which the further traverse of the triple-valve piston beyond the extent of the traverse required for the ordinary application of the brakes, is made to admit a large volume of train-pipe air directly to the brake-cylinder, was one of great importance. The proofs show that a quick-action automatic brake, which would give the results which this brake has accomplished, was eagerly

Opinion of the Court.

sought after by inventors and car builders, and all had failed until Westinghouse discovered that it could be done by this mode of operation."

We are now in position to take up the several claims of the patent in suit, and their defences thereto. It may be stated generally that the position of complainants in this connection is, that the novel feature of this patent, in respect to which they are entitled to be protected, is the opening of a passage directly from the train-pipe to the brake-cylinder, without passing through the auxiliary reservoir and without reference to the means by which such passageway is controlled. Defendant's theory is that they are limited to such passageway when governed by the auxiliary valve 41, a device which, although of no utility as arranged in the patent in suit, became afterwards exceedingly useful when further combined with the supplementary piston shown in patent No. 376,837. The further inference is that, as they do not use the auxiliary valve of this patent, they cannot be held liable as infringers.

Complainants' case must rest either upon the theory that the admission of compressed air directly from the train-pipe to the brake-cylinder is patentable as a function, or that the means employed by the defendants for that purpose are a mechanical equivalent for the auxiliary valve 41, described in the patent.

1. The first theory is based upon the second claim, which is "in a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder and a triple-valve having a piston, whose preliminary traverse admits air from the auxiliary reservoir to the brake-cylinder, and which by a further traverse admits air directly from the main air-pipe to the brake-cylinder, substantially as set forth."

In the construction of this claim, the District Judge was of opinion that it was broad enough to cover other devices in which air was admitted directly from the train-pipe to the brake-cylinder by the further traverse of the piston actuating a valve admitting such air, and that the defendants could not exculpate themselves from the charge of infringement, from the fact that in their device the train-pipe air was admitted

Opinion of the Court.

through the triple-valve chamber, and not through a by-passage, nor by the fact that in their device the further traverse of the piston opens the main valve in a special manner, which produces the same result, but does not make use of a separate auxiliary valve.

Upon the other hand, the Circuit Court of Appeals held that "the transmission of train-pipe air and auxiliary reservoir air simultaneously to the brake-cylinder is a result of [or] function, and is not patentable;" that "the means by which this or any other result or function is accomplished may be many and various, and if these several means are not mechanical equivalents, each of them is patentable." It was of opinion that when the second claim, "in its language describing the action of that device, failed to describe any means by which the extreme traverse of the piston produced it, declaring merely that the piston, 'by a further traverse, admits air directly from the main air-pipe to the brake-cylinder,' it was fatally defective, claiming only a result which is public property, and not identifying the specific means (his own property) by which the result is achieved."

It is true, as observed by the Court of Appeals, that the further traverse of the piston for use in cases of emergency had been shown in prior patents, but it had never been employed for the purpose of admitting air directly from the main air-pipe to the brake-cylinder until the patent in suit was taken out.

The claim in question is, to a certain extent, for a function, viz., the admission of air directly from the train-pipe to the brake-cylinder, and is only limited to such function when performed by the further traverse of the piston of the triple-valve. This limitation, however, does not obviate the objection that the means are not fully and specifically set forth for the performance of the function in question.

The difficulty we have found with this claim is this: That, if it be interpreted simply as a claim for the function of admitting air to the brake-cylinder directly from the train-pipe, it is open to the objection, held in several cases to be fatal, that the mere function of a machine cannot be patented.

Opinion of the Court.

This rule was clearly laid down in the leading case of *Corning v. Burden*, 15 How. 252, in which Mr. Justice Grier, delivering the opinion of the court, drew the distinction between such processes as were the result or effect of "chemical action, by the operation or application of some element or power of nature, or of one substance to another," and the mere result of the operation of a machine, with regard to which he says:

"It is for the discovery or invention of some practicable method or means of producing a beneficial result or effect that a patent is granted, and not for the result or effect itself. It is when the term 'process' is used to represent the means or method of producing a result that it is patentable, and it will include all methods or means which are not effected by mechanism or mechanical combinations.

"But the term 'process' is often used in a more vague sense, in which it cannot be the subject of a patent. Thus we say that a board is undergoing the process of being planed, grain of being ground, iron of being hammered or rolled. Here the term is used subjectively or passively as applied to the material operated on, and not to the method or mode of producing that operation, which is by mechanical means, or the use of a machine, as distinguished from a process."

"In this use of the term it represents the function of a machine, or the effect produced by it on the material subjected to the action of the machine. But it is well settled that a man cannot have a patent for the function or abstract effect of a machine, but only for the machine which produces it."

In the subsequent case of *Burr v. Duryee*, 1 Wall. 531, 570, Mr. Justice Grier laid down the same principle as follows:

"The patent act grants a monopoly 'to any one who may have discovered or invented any new and useful art, machine, manufacture or composition of matter.' . . . The law requires that the specification 'should set forth the principle and the several modes in which he has contemplated the application of that principle, or character by which it may be distinguished from other inventions, and shall particularly point out the part, improvement or combination which he claims as

Opinion of the Court.

his own invention or discovery.' We find here no authority to grant a patent for a 'principle' or 'a mode of operation,' or an *idea*, or any other abstraction. A machine is a concrete thing, consisting of parts, or of certain devices and combination of devices. The principle of a machine is properly defined to be its mode of operation, or that peculiar combination of devices which distinguishes it from other machines. A machine is not a principle or an idea. The use of ill defined abstract phraseology is the frequent source of error. It requires no great ingenuity to mystify a subject by the use of abstract terms of indefinite or equivocal meaning. Because the law requires a patentee to explain the mode of operation of his peculiar machine, which distinguishes it from others, it does not authorize a patent for 'a mode of operation as exhibited in the machine.' Much less can any inference be drawn from the statute, that an inventor who has made an improvement in a machine, and thus effects the desired result in a better or cheaper manner than before can include all previous inventions and have a claim to the whole art, discovery or machine which he has improved. All others have an equal right to make improved machines, provided they do not embody the same, or substantially the same devices, or combination of devices, which constitute the peculiar characteristics of the previous invention."

So also in *Fuller v. Yentzer*, 94 U. S. 288, this court, speaking through Mr. Justice Clifford, said :

"Patents for a machine will not be sustained if the claim is for a result, the established rule being that the invention, if any, within the meaning of the Patent Act, consists in the means or apparatus by which the result is obtained, and not merely in the mode of operation independent of the mechanical devices employed; nor will a patent be held valid for a principle or for an idea, or any other mere abstraction."

Most of the prior authorities upon this subject are reviewed in the recent case of *Risdon Locomotive Works v. Medart*, 158 U. S. 68, in which it was also held that a valid patent could not be obtained for a process which involved nothing more than the operation of a piece of mechanism, or the func-

Opinion of the Court.

tion of a machine. See also to the same effect *Wicke v. Ostrum*, 103 U. S. 461, 469. These cases assume, although they do not expressly decide, that a process to be patentable must involve a chemical or other similar elemental action, and it may be still regarded as an open question whether the patentability of processes extends beyond this class of inventions. Where the process is simply the function or operative effect of a machine, the above cases are conclusive against its patentability; but where it is one which, though ordinarily and most successfully performed by machinery, may also be performed by simple manipulation, such, for instance, as the folding of paper in a peculiar way for the manufacture of paper bags, or a new method of weaving a hammock, there are cases to the effect that such a process is patentable, though none of the powers of nature be invoked to aid in producing the result. *Eastern Paper Bag Co. v. Standard Paper Bag Co.*, 30 Fed. Rep. 63; *Union Paper Bag Machine Co. v. Waterbury*, 39 Fed. Rep. 389; *Travers v. Am. Cordage Co.*, 64 Fed. Rep. 771. This case, however, does not call for an expression of our opinion upon this point, nor even upon the question whether the function of admitting air directly from the train-pipe to the brake-cylinder be patentable or not, since there is no claim made for an independent process in this patent, and the whole theory of the specification and claims is based upon the novelty of the mechanism.

But if the second claim be not susceptible of the interpretation that it is simply for a function, then the performance of that function must be limited to the particular means described in the specification for the admission of air from the train-pipe to the brake-cylinder. This we understand to be the theory of the defendants, and this raises the same question which is raised under the first and fourth claims, whether defendants' device contains the auxiliary valve of the Westinghouse patent, or its mechanical equivalent.

In this view, it becomes unnecessary to express an opinion whether the second claim be valid or not, since in the aspect of the case most favorable to the complainants, it is necessary to read into it something which is not found there, or, in the

Opinion of the Court.

language of complainants' brief, "to refer back to the specification; not, it is true, for a slavish adoption of the identical instrumentalities therein described, but for the understanding of the essential and substantial features of the means therein illustrated." In thus reading the specification into the claim, we can adopt no other construction than to consider it as if the auxiliary valve were inserted in the claim in so many words, and then to inquire whether the defendants make use of such valve, or its mechanical equivalent.

There are two other facts which have a strong bearing in the same connection, and preclude the idea that this can be interpreted as a claim for a function, without reading into it the particular device described in the specification.

One of these is that the claim is for a triple-valve device, etc., for admitting air from the main air-pipe to the brake-cylinder, "substantially as set forth." These words have been uniformly held by us to import into the claim the particulars of the specification, or, as was said in *Seymour v. Osborne*, 11 Wall. 516, 547, "where the claim immediately follows the description of the invention, it may be construed in connection with the explanations contained in the specifications, and where it contains words referring back to the specifications, it cannot be properly construed in any other way." In that case it was held that a claim which might otherwise be bad, as covering a function or result, when containing the words "substantially as described," should be construed in connection with the specification, and when so construed was held to be valid. To the same effect is *The Corn Planter Patent*, 23 Wall. 181, 218.

Again, it appears from the file-wrapper and contents, that in his original application Mr. Westinghouse made a broad claim for the admission of air directly from the main air-pipe to the brake-cylinder, which was rejected upon reference to a prior patent to Boyden, No. 280,285, and that on January 19, 1887, his attorney wrote the Patent Office in the following terms:

"It is respectfully submitted that while the Boyden patent No. 280,285 referred to, shows that what the inventor terms

Opinion of the Court.

'an always-open one-way passage,' by which communication may be established under certain conditions, between the main air-pipe or train-pipe, and hence might be held to meet the terms of the claim as originally broadly drawn, yet it fails to embody a device which in structure or function corresponds with the auxiliary valve of applicant, which in no sense relates to 'an always-open one-way passage.' This amended claim, above submitted, prescribes a valve device actuated by the piston of the triple-valve for admitting air to the brake-cylinder in the application of the brake, while Boyden's check-valve *d* is not actuated by the piston, and is designed to recharge the auxiliary reservoir and brake-cylinder while the brakes are on. It is submitted, as to claim 2, that a piston, which by its preliminary traverse, admits air from the auxiliary reservoir to the brake-cylinder and by its further traverse admits air directly from the main air-pipe to the brake-cylinder, as set forth in said claim, is not found in the Boyden patent, the check-valve *d* of which is described as actuated by the manipulation of the cock *q* on the locomotive to 'recharge and continue charging the reservoir and brake-cylinder while the brakes are applied.' . . . It is to be understood that applicant *does not seek to broadly claim a device for admitting air directly from the main air-pipe to the brake-cylinder*, as the four-way cock long heretofore employed by him (similar to the cock *K* of the Boyden patent) would be a structure of such character. When, however, the triple-valve is provided with an *auxiliary valve, operated by its piston which performs a new function* additional to that of the triple-valve as previously employed, it is believed that such *combination* is wholly novel."

So, too, in the specification it is stated:

"So far as the performance of its preliminary function in ordinary braking is concerned — that is to say, effecting the closure of communication between the main air-pipe and the auxiliary reservoir, and the opening of communication between the auxiliary reservoir and the brake-cylinder in applying the brakes, and the reverse operations in releasing the brakes — the triple-valve 10 accords substantially with that set forth in letters patent of the United States No. 220,556, granted and

Opinion of the Court.

issued to me October 14, 1879, and is not, therefore, saving as to the *structural features* by which it performs the further function of effecting the direct admission of air from the main air-pipe to the brake-cylinder, as presently to be described, claimed as of my present invention."

Apparently, too, in consequence of the above letter of January 19, 1887, the patentee erased from his original specification the following sentence: "Further, while in the specific construction described and shown, the function of admitting air from the main pipe is performed by a valve separate from that which effects the preliminary admission of reservoir pressure to the cylinder, a modification in which the same office is performed by a valve integral with the main valve and formed by an extension thereof, would be included in and embody the essential operative features of my invention," and inserted in its place the following: "I am aware that a construction in which 'an always-open one-way passage' from the main air-pipe to the brake-cylinder is uncovered by the piston of the triple-valve simultaneously with the opening of the passage from the auxiliary reservoir to the brake-cylinder, has been heretofore proposed, and such construction, which involves an operation different from that of my invention, I therefore hereby disclaim."

We agree with the defendant that this correspondence, and the specification as so amended, should be construed as reading the auxiliary valve into the claim, and as repelling the idea that this claim should be construed as one for a method or process. Language more explicit upon this subject could hardly have been employed.

While it is true that no claim is formally made for the admission of train-pipe air directly to the brake-cylinder as a method or process, a construction is given by the complainants and the Circuit Court to the second claim which eliminates the mechanical features described, and one which could only be supported upon the theory that the claim was for a method or process. If the mechanism described by Westinghouse, and particularly the auxiliary valve, be not essential to the validity of the second claim, then it could only be supported

Opinion of the Court.

upon the theory that it was for the process of admitting train-pipe air directly to the brake-cylinder.

2. The first and fourth claims of this patent are as follows :

"1. In a brake mechanism, the combination of a main air-pipe, an auxiliary reservoir, a brake-cylinder, a triple-valve and an auxiliary valve device, actuated by the piston of the triple-valve and independent of the main valve thereof, for admitting air in the application of the brake directly from the main air-pipe to the brake-cylinder, substantially as set forth."

"4. The combination, in a triple-valve device, of a case or chest, a piston fixed upon a stem and working in a chamber therein, a valve moving with the piston-stem and governing ports and passages in the case leading to connections with an auxiliary reservoir and a brake-cylinder and to the atmosphere, respectively, and an auxiliary valve actuated by the piston-stem and controlling communication between passages leading to connections with a main air-pipe and with the brake-cylinder, respectively, substantially as set forth."

These two claims are practically little more than different expressions of one and the same invention. In both of them there is a main air-pipe, an auxiliary reservoir, a brake-cylinder, a triple-valve and piston, described in the fourth claim as "fixed upon a stem and working in a chamber" in a case or chest, and an auxiliary valve; and in the fourth claim also a case or chest, which contains the whole device and is immaterial.

In both of these claims an auxiliary valve is named as an element. In the first it is described as "actuated by the piston of the triple-valve and independent of the main valve thereof;" and in the fourth as "actuated by the piston-stem and controlling communication between passages leading to connections with the main air-pipe and with the brake-cylinder."

To what liberality of construction these claims are entitled depends to a certain extent upon the character of the invention, and whether it is what is termed in ordinary parlance a "pioneer." This word, although used somewhat loosely, is commonly understood to denote a patent covering a function

Opinion of the Court.

never before performed, a wholly novel device, or one of such novelty and importance as to mark a distinct step in the progress of the art, as distinguished from a mere improvement or perfection of what had gone before. Most conspicuous examples of such patents are: The one to Howe of the sewing machine; to Morse of the electrical telegraph; and to Bell of the telephone. The record in this case would indicate that the same honorable appellation might be safely bestowed upon the original air-brake of Westinghouse, and perhaps also upon his automatic brake. In view of the fact that the invention in this case was never put into successful operation, and was to a limited extent anticipated by the Boyden patent of 1883, it is perhaps an unwarrantable extension of the term to speak of it as a "pioneer," although the principle involved subsequently and through improvements upon this invention became one of great value to the public. The fact that this invention was first in the line of those which resulted in placing it within the power of an engineer, running a long train, to stop in about half the time and half the distance within which any similar train had stopped, is certainly deserving of recognition, and entitles the patent to a liberality of construction which would not be accorded to an ordinary improvement upon prior devices. At the same time, as hereinafter observed, this liberality must be exercised in subordination to the general principle above stated: that the function of a machine cannot be patented, and, hence, that the fact that the defendants' machine performs the same function is not conclusive that it is an infringement.

The device made use of by the defendants is exhibited in patents No. 481,134 and No. 481,135, both dated August 16, 1892, and both of which were granted after the commencement of this suit. There are two forms of this patent, one of which, illustrated in patent No. 481,135, is here given on the opposite page in its three positions of release (20), service application (21), and quick action (22).

In this device there is found a main air-pipe, an auxiliary reservoir, a brake-cylinder, a triple, or rather a quadruple, valve and piston (29) with three ports; first, for the admission

Opinion of the Court.

of air from the train-pipe to the brake-cylinder through the feeding-in valve 26; second, for the passage of air from the auxiliary reservoir to the brake-cylinder through the apertures *i, j, k* in the stem slide-valve 18; and, third, for the release of air from the brake-cylinder to the exhaust port by means of valve 17, colored green. Whether this device has an auxiliary valve or not is one of the main questions in the case, complainants' theory being that poppet-valve 22 is an auxiliary valve, while defendants' claim is that it is in reality the main valve.

The operation of this device is best shown by the foregoing skeleton drawings.

The auxiliary reservoirs are charged by air under pressure,

Opinion of the Court.

entering from the train-pipe, raising and passing through the feeding-in valve piston 26, and flowing slowly into and through the passage A to the auxiliary reservoir, until such reservoir is filled. In this condition the brake-cylinder is emptied and opened to the atmosphere through the exhaust passage G.

In order to apply the brakes gradually, so as to slacken speed or make an ordinary stop, air pressure in the train-pipe is reduced slightly (say from three to five pounds) by action of the engineer's valve, and the reduction of pressure on the right side of the piston 29 causes the piston to make what is termed a "preliminary traverse" to the position shown in diagram "Service Application." Such preliminary traverse pulls the stem slide-valve 18 to the right, and opens the apertures *i*, *j* and *k*, (one of these apertures being to the right and the other to the left of valve 22,) and through these apertures air rushes from the auxiliary reservoir to the brake-cylinder; but the poppet-valve 22 still remains upon its seat.

If quick action be required, the pressure in the train-pipe is suddenly lowered to the extent of fifteen or twenty pounds, and the travelling piston 29, instead of making a preliminary traverse to the intermediate position shown in the "Service Application," makes a full traverse to the extreme right, the effect of which is that the valve 22 is pulled off its seat by the collar M, and a large passage is opened to the brake-cylinder under the valve 22 and around the stem 18. The result is, as shown in the last diagram, that not only does the air in the auxiliary reservoir escape in full volume to the brake-cylinder, but air from the train-pipe rushes directly to the brake-cylinder through the large passage F into the chamber C and under valve 22.

The argument of the defendants in this connection is that, in this device, there is no auxiliary valve or by-passage, but the quick-action result is effected simply by proportioning the ports and passages of the old triple-valve, and using a fixed partition, 9, to divide the piston chamber D from the main-valve chamber C; that it is this partition which produces the quick action, and that such partition is not a valve, nor the mechanical equivalent of a valve, but merely a metal ring

Opinion of the Court.

screwed immovably into the triple-valve casing, and serving to divide the piston-chamber from the main-valve chamber; that this partition was a new element, never before found in triple valves, and introduced a new principle and mode of operation, totally different from anything ever invented by Mr. Westinghouse or any other inventor, and that its effect is to make valve 22, termed by them the main valve, admit the train-pipe air to the brake-cylinder at the same time that it admits the auxiliary air thereto.

It is claimed that, in embodying this new principle, Mr. Boyden adopted the form of triple-valve shown in the expired Westinghouse patent No. 141,685, (1873,) in which the main valve, 22, is of the poppet form, and the separate valve 17, controlled by a rod sliding through the main valve, is employed for releasing the brakes. For charging the auxiliary reservoir he adopted, from the expired Westinghouse patent No. 144,006, (1873,) a check-valved feed passage through the triple-valve piston, but arranged the feed passage and its check-valve, 26, in a tubular extension, F, of the piston, and substantially in the form shown in Boyden patent No. 280,285, (1883). He also provided a sensitive graduating valve, similar in results to the graduating valve *e'* of the Westinghouse patent No. 220,556, (1879,) by so arranging a small passage, 40, in the sliding stem, which actuates the release valve, that such passage will be opened and closed by the sliding of such stem through the main valve 22. As thus constructed, the triple-valve operates much the same as that of patent No. 220,556, and, like the latter, is incapable of quick action.

In both the complainants' and defendants' devices there is: (1) a feeding-in valve to charge the auxiliary reservoir; (2) a valve which complainants call their "main valve," and which the defendants denominate a "graduating valve," which is opened by the preliminary traverse of the piston to admit reservoir air to the brake-cylinder; (3) a release valve which discharges air from the brake-cylinder to the atmosphere; and (4) a quick-action valve — 41 in the complainants' patent, and 22 in the defendants' — which is opened by the further traverse of the piston to admit train-pipe air to the brake-

Opinion of the Court.

cylinder. In defendants' patent, it may also be used to admit auxiliary reservoir air to the brake-cylinder.

One of the main controversies in the case turns upon the construction and operation of the poppet-valve 22, called by the defendants their "main-valve." Complainants insist that the office of *their* main valve is performed by the stem slide-valve 18 of defendants' patent, and by its apertures *i, j* and *k*, through which air passes from the auxiliary reservoir to the brake-cylinder, and that the poppet-valve 22 is only called into action in emergency cases, when a large quantity of air is suddenly withdrawn from the train-pipe, and the valve is unseated by the traverse of the piston to the extreme right.

There is no doubt that the function of admitting air from the auxiliary reservoir to the brake-cylinder, which is performed in the Westinghouse patent by what the complainants term the main-valve, (aided, however, by the graduating-valve,) is, in ordinary cases, performed principally, if not altogether, by the stem slide-valve 18 and its three ports *i, j, k*, of the Boyden patent, which defendants term their graduating-valve. It is equally clear that, in emergencies, where quick action is required, air, which in the Westinghouse patent passes through auxiliary valve 41, (opened by the further traverse of the piston,) in the Boyden patent finds its way through the poppet-valve 22, which has also been lifted from its seat by the further traverse of the piston.

One of the main differences between the two devices is this: That in the preliminary traverse of the piston of the Westinghouse patent, there is a movement, first, of the graduating-valve to open its port from the auxiliary reservoir, and then of the main valve, carrying the graduating-valve also with it, to open a passage to the brake-cylinder, while in the Boyden patent it is only the graduating-valve which is opened by the preliminary traverse of the piston. In doing this, the graduating-valve moves *through* the poppet-valve, but does not lift it from its seat. In emergency cases not only do the graduating-valve and the main-valve of the Westinghouse patent move as before, but, by the extreme traverse of the piston, the auxiliary-valve 41 is shoved from its seat, and a separate

Opinion of the Court.

passage is opened for the air from the train-pipe to the brake-cylinder. In the Boyden patent, however, the extreme traverse of the piston lifts the poppet-valve from its seat, and opens a wide passage to the brake-cylinder, not only for the air from the auxiliary reservoir, but, through the peculiar operation of the partition 9 and its aperture B, directly from the train-pipe. As the graduating-valve of the Boyden patent practically does all the work in ordinary cases, and the poppet-valve is only called into action in emergency cases, the latter is practically an auxiliary valve, by which, we understand, not necessarily an independent valve, nor one of a particular construction, but simply a valve which in emergency cases is called into the assistance of the graduating-valve. In this particular, the poppet-valve of the Boyden device performs practically the same function as the slide-valve 41 of the Westinghouse. It is not material in this connection that it is a poppet-valve while the other is a slide-valve, since there is no invention in substituting one valve or spring of familiar shape for another; *Imhaeuser v. Buerk*, 101 U. S. 647, 656; nor, that in one case the piston *pushes* the valve off its seat, and in the other *pulls* it off; nor is it material that this poppet-valve may have been used in prior patents to perform the function of a main-valve, so long as it is used for a different purpose here. Indeed, this valve seems to have been taken bodily from Westinghouse patent No. 141,685, where it was used as a main-valve, and the stem-valve 18 with its ports *i*, *j*, *k*, added for ordinary uses, and the poppet-valve thus converted from a main-valve to an auxiliary valve.

We have not overlooked in this connection the argument that the poppet-valve 22 is also sometimes used for graduating purposes, but it is not commonly so used, and appears to be entirely unnecessary for that purpose. It seems to be possible to move the piston 29 to its extreme traverse so slowly, and hence to open valve 22 so gradually, that the pressure in the chamber C will be reduced so slightly, that the train-pipe air will not have sufficient force to throw open the check-valve 26, and hence, in such case no train-pipe air will be admitted directly to the brake-cylinder, which will be filled with auxil-

Opinion of the Court.

iary reservoir air only. But, as a matter of fact, this seldom or never takes place in the practical operation of the device, and is an unnecessary and wholly unimportant incident, and for all practical purposes valve 22 is solely a quick-action valve. As this valve is actuated by the piston of the triple-valve, and in such action is independent of the main valve, it meets the demand of the first claim of the patent, and as it is actuated by the piston-stem, and controls communication between passages leading to connections with the main air-pipe and with the brake-cylinder, it seems also to be covered by the fourth claim.

But even if it be conceded that the Boyden device corresponds with the letter of the Westinghouse claims, that does not settle conclusively the question of infringement. We have repeatedly held that a charge of infringement is sometimes made out, though the letter of the claims be avoided. *Machine Co. v. Murphy*, 97 U. S. 120; *Ives v. Hamilton*, 92 U. S. 426, 431; *Morey v. Lockwood*, 8 Wall. 230; *Elizabeth v. Pavement Company*, 97 U. S. 126, 137; *Sessions v. Romadka*, 145 U. S. 29; *Hoyt v. Horne*, 145 U. S. 302. The converse is equally true. The patentee may bring the defendant within the letter of his claims, but if the latter has so far changed the principle of the device that the claims of the patent, literally construed, have ceased to represent his actual invention, he is as little subject to be adjudged an infringer as one who has violated the letter of a statute has to be convicted, when he has done nothing in conflict with its spirit and intent. "An infringement," says Mr. Justice Grier in *Burr v. Duryee*, 1 Wall. 531, 572, "involves substantial identity, whether that identity be described by the terms, 'same principle,' same '*modus operandi*,' or any other. . . . The argument used to show infringement assumes that every combination of devices in a machine which is used to produce the same effect, is necessarily an equivalent for any other combination used for the same purpose. This is a flagrant abuse of the term 'equivalent.'"

We have no desire to qualify the repeated expressions of this court to the effect that, where the invention is functional, and the defendant's device differs from that of the patentee

Opinion of the Court.

only in form, or in a rearrangement of the same elements of a combination, he would be adjudged an infringer, even if, in certain particulars, his device be an improvement upon that of the patentee. But, after all, even if the patent for a machine be a pioneer, the alleged infringer must have done something more than reach the same result. He must have reached it by substantially the same or similar means, the rule that the function of a machine cannot be patented is of no practical value. To say that the patentee of a pioneer invention for a new mechanism is entitled to every mechanical device which produces the same result is to hold, in other language, that he is entitled to patent his function. Mere variations of form may be disregarded, but the substance of the invention must be there. As was said in *Burr v. Duryee*, 1 Wall. 531, 573, an infringement "is a copy of the thing described in the specification of the patentee, either without variation, or with such variations as are consistent with its being in substance the same thing. If the invention of the patentee be a machine, it will be infringed by a machine which incorporates in its structure and operation the substance of the invention; that is, by an arrangement of mechanism which performs the same service or produces the same effect in the same way, or substantially the same way. . . . That two machines produce the same effect will not justify the assertion that they are substantially the same, or that the devices used are, therefore, mere equivalents for those of the other."

Not only is this sound as a general principle of law, but it is peculiarly appropriate to this case. Under the very terms of the first and fourth claims of the Westinghouse patent, the infringing device must not only contain an auxiliary valve, or its mechanical equivalent, but it must contain the elements of the combination "substantially as set forth." In other words, there must not only be an auxiliary valve, but substantially such a one as is described in the patent, *i.e.* independent of the triple-valve. Not only has the Boyden patent a poppet instead of a slide-valve—a matter of minor importance—but it performs a somewhat different function. In the Westinghouse patent the valve is not in the line of travel between the

Opinion of the Court.

auxiliary reservoir and the brake-cylinder, and admits train-pipe air only. In the Boyden patent, it is in the line of travel, both from the auxiliary reservoir and from the train-pipe, and admits both currents of air to the brake-cylinder. The by-passage, to which the auxiliary reservoir is merely an adit, is wholly wanting in the Boyden device, both currents of air uniting in chamber C and passing to the brake-cylinder together, through the poppet-valve.

But a much more radical departure from the Westinghouse patent is found in the partition 9, separating the valve-chamber C from the piston-chamber D. This partition has an aperture, B, the capacity of which is less than that of the large passage A, and intermediate in size between that of the graduating passage 40, and that of the port covered by the valve 22. The office of this partition is thus explained by the defendants in their briefs: When the engineer's valve is thrown wide open, the poppet-valve is lifted from its seat by the extreme traverse of the piston, and a new action takes place. "The port of the main valve 22 is so much larger than the passage B, that the pressure in the main valve-chamber C is instantly emptied into the brake-cylinder, and, as the passage B cannot supply air so fast as the main-valve port can exhaust it, the pressure in the main valve-chamber suddenly drops to about five pounds. Meanwhile the passage A, leading from the auxiliary reservoir to the inner end of the piston-chamber, is so much larger than the passage B, leading from the piston-chamber to the main valve-chamber, that full reservoir pressure is maintained in the piston-chamber between the partition 9 and the inner side of the piston, thereby holding the piston back firmly at its extreme traverse. But the feed-valve 26 is now exposed on the one side to a train-pipe pressure of about fifty-five pounds, and on the other side to a main valve-chamber pressure of only about five pounds, and therefore valve 26 is instantly forced open by the greater train-pipe pressure, which then vents freely through the said feed valve-port into the main valve-chamber C where it commingles with the auxiliary reservoir air passing through said chamber, and both airs pass together through the port opened by the main valve 22

Opinion of the Court.

to the brake-cylinder. The whole operation is substantially instantaneous, and the result is that the train-pipe is freely vented at each car, the time of serially or successively applying the brakes of the several cars from one end of the train to the other is reduced to a minimum, and the train is quickly stopped without shock, a result which Mr. Westinghouse did not attain with the device of patent No. 360,070, nor did he attain it until he had invented his later apparatus of patent No. 376,837, not here in suit."

In a word, this partition maintains upon the outside of valve 26 a much higher pressure than upon the inside, the effect of which is to open feed-valve 26 and admit a full volume of train-pipe air upon the brake-cylinder.

Conceding that the functions of the two devices are practically the same, the means used in accomplishing this function are so different that we find it impossible to say, even in favor of a primary patent, that they are mechanical equivalents. While the poppet-valve, which for the purposes of this case, we may term the auxiliary valve, is in its operation independent of the main valve, the word "independent" in the claims of the Westinghouse patent evidently refers to a valve auxiliary to the triple-valve, and independently located as well as operated. The difference is that in one case the air from the train-pipe is introduced into the brake-cylinder separately and independently from the air from the auxiliary reservoir; while in the other case they unite in the chamber C and pass through the same valve to the brake-cylinder. In the Westinghouse patent there is one valve operated by the direct thrust of the piston, opening a by-passage; in the other, there is a poppet-valve also opened by the piston, and another valve, 26, opened by the pressure maintained upon the outside of the partition 9.

It is claimed, however, by the complainants that Boyden was not the inventor of the differential pressure theory; that there is such a differential pressure in their own patent, caused by the fact that the air from the auxiliary reservoir in passing to the brake-cylinder travels through a restricted port, 35, and, as the entrance to the brake-cylinder is through a much larger port, the air is taken up by it much more rapidly than it is

Opinion of the Court.

supplied by the restricted port, which reduces the pressure in the by-passage so much that when the quick-action valve 41 is opened, the pressure from the train-pipe air is sufficient to open the valve 49 and admit a full volume of train-pipe air, at a pressure of fifty-five pounds, to the brake-cylinder. The fact, however, that no suggestion is made in the patent of such a function of the restricted port 35, indicates either that none such had been discovered, or that it was not considered of sufficient importance to mention it. Indeed, it seems to have been an afterthought, suggested by the necessity of an answer to defendants' argument, based upon their partition 9. That when the auxiliary valve is opened there must be a difference in pressure above and below the check-valve 49, in order to open it, is manifest; yet, this is rather an incident to the Westinghouse device than the controlling feature that it is made in the Boyden patent. There is no partition in the proper sense of the word — certainly none located as in the Boyden device — between the chambers D and C, and no aperture in such partition opened for the express purpose of maintaining this differential pressure. If such differential pressure existed to the extent claimed in the Westinghouse patent, it certainly was not productive of the results flowing from the same device in the Boyden patent.

We are induced to look with more favor upon this device, not only because it is a novel one and a manifest departure from the principle of the Westinghouse patent, but because it solved at once in the simplest manner the problem of quick action, whereas the Westinghouse patent did not prove to be a success until certain additional members had been incorporated into it. The underlying distinction between the two devices is that in one, a separate valve and separate by-passage are provided for the train-pipe air, while in the other, the patentee has taken the old triple (or quadruple) valve, and by a slight change in the functions of two of its valves and the incorporation of a new element, (partition 9,) has made a more perfect brake than the one described in the Westinghouse patent. If credit be due to Mr. Westinghouse for having invented the function, Mr. Boyden has certainly exhibited

Dissenting Opinion: Shiras, Brewer, JJ.

great ingenuity in the discovery of a new and more perfect method of performing such function. If his patent be compared with the later Westinghouse patent No. 376,837, which appears to have been the first completely successful one, the difference between the two, both in form and principle, becomes still more apparent, and the greater simplicity of the Boyden patent certainly entitles it to a favorable consideration. If the method pursued by the patentee for the performance of the function discovered by him would naturally have suggested the device adopted by the defendants, that is in itself evidence of an intended infringement; but, although Mr. Boyden may have intended to accomplish the same results, the Westinghouse patent, if he had had it before him, would scarcely have suggested the method he adopted to accomplish these results. Under such circumstances, the law entitles him to the rights of an independent inventor.

Upon a careful consideration of the testimony we have come to the conclusion that the Boyden device is not an infringement of the complainants' patent, and the decree of the Circuit Court of Appeals is, therefore,

Affirmed.

MR. JUSTICE SHIRAS, with whom concurred MR. JUSTICE BREWER, dissenting.

I am unable to concur in the reasoning and conclusion of the court, and shall briefly state my views.

The history of the art discloses that the patent in suit was what is called a "pioneer invention." In it, for the first time, was brought to light a method or process which, by the co-operation of the air from the train-pipe with that from the car reservoir, created the "quick action" brake. The patent, in its specification and claims, clearly described a machine or mechanical combination whereby the invention was exemplified or rendered operative.

It is not an unwarrantable extension of the term to speak of this invention in suit as a pioneer, since it is practically conceded in this case, and justly observed by the court below,

Dissenting Opinion: Shiras, Brewer, JJ.

"one of the highest value to the public," and conspicuously one "which entitles the proprietor to a liberal protection from the courts in construing the claim." The very fact that this invention resulted in placing it within the power of an engineer, running a long train, to stop in about half the time and half the distance within which any similar train had been stopped, is certainly deserving of recognition. The claims of such patents have from time out of mind been allowed a liberal construction, and considered as entitled to the fullest benefit of the doctrine of mechanical equivalents.

It in nowise detracts from the merit of this invention that later devices have been adopted which render its practical operation more efficient. The very term, "pioneer patent," signifies that the invention has been followed by others. A pioneer patent does not shut, but opens the door for subsequent invention.

The particular patent in suit was, as I understand it to be admitted, an entire success in supplying passenger trains and short freight trains with a "quick action" brake; but while it enabled even the longest freight trains to stop in half the time and half the distance previously occupied, there remained difficulties which required further devices to give to the invention the perfect success which it has now attained.

Being of the character so described as a pioneer, the patent in suit is entitled to a broad or liberal construction. In other words, the invention is not to be restricted narrowly to the mere details of the mechanism described as a means of carrying the invention into practicable operation.

I cannot assent to what is, perhaps, rather intimated than decided in the opinion of the court that what is called a "process in order to be patentable must involve a chemical or other similar elemental action." The term "process" or "method," as describing the subject of a patent, is not found in the statutes. No reason is given in the authorities, and I can think of none in the nature of things, why a new process or method may not be patentable, even though a mechanical device or a mechanical combination may be necessary to render the new process practicable. It seems to be used by the courts

Dissenting Opinion: Shiras, Brewer, JJ.

as descriptive of an invention which, from its novelty and priority in the art to which it belongs, is not to be construed as inhering only in the particular means described, in the letters patent, as sufficient to exemplify the invention and bring it into practical use.

Thus in the case of *Winans v. Dormead*, 15 How. 330, 341, the patent was for a new form of the body of a car for the transportation of coal, thus avoiding certain practical difficulties or disadvantages in such cars as previously made. To the argument on behalf of the infringer, that the claim of the patent was confined to a single form, and only through and by that form to the principle which it embodies, this court said, per Mr. Justice Curtis:

"It is generally true that when a patentee describes a machine, and then claims it as described, he is understood to intend to claim, and does by law actually cover, not only the precise form he has described, but all other forms which embody his invention; it being a familiar rule that to copy the principle or mode of operation described is an infringement, although such copy should be totally unlike the original in form or proportions. . . . It is not sufficient to distinguish this case to say that here the invention consists in a change of form, and the patentee has claimed one form only. Patentable improvements in machinery are almost always made by changing some one or more forms of one or more parts, and thereby introducing some mechanical principle or mode of action not previously existing in the machine, and so securing a new or improved result. And in the numerous cases in which it has been held that to copy the patentee's mode of operation was an infringement, the infringer had got forms and proportions not described, and not in terms claimed. If it were not so, no question of infringement could arise. If the machine complained of were a copy, in form, of the machine described in the specification, of course, it would be at once seen to be an infringement. It could be nothing else. It is only ingenious diversities of form and proportion, presenting the appearance of something unlike the thing patented, which give rise to questions; and the property of inventors would be valueless

Dissenting Opinion: Shiras, Brewer, JJ.

if it were enough for the defendant to say: Your improvement consisted in a change of form; you describe and claim but one form; I have not taken that, and so have not infringed.

"The answer is: My infringement did not consist in a change of form, but in the new employment of principles or powers, in a new mode of operation, embodied in a form by means of which a new or better result is produced; it was this which constituted my invention; this you have copied, changing only the form. . . . Where form and substance are inseparable it is enough to look at the form only. Where they are separable — where the whole substance of the invention may be copied in a different form, it is the duty of courts and juries to look through the form for the substance of the invention — for that which entitled the inventor to his patent, and which the patent was designed to secure; where that is found there is an infringement; and it is not a defence that it is embodied in a form not described and in terms claimed by the patentee. Patentees sometimes add to their claims an express declaration to the effect that the claim extends to the thing patented, however its form or proportions may be varied. But this is unnecessary. The law so interprets the claim without the addition of these words."

McCormick v. Talcott, 20 How. 402, 405, was also a case of a mechanical patent, and it was said by Mr. Justice Grier, who delivered the opinion of the court: If the patentee "be the original inventor of the device or machine, called the divider, he will have a right to treat as infringers all who make dividers operating on the same principle and performing the same functions by analogous means or equivalent combination, even though the infringing machine may be an improvement of the original and patentable as such."

In *Morley Sewing Machine Co. v. Lancaster*, 129 U. S. 263, there was also a question of an alleged invention of a primary character, and wherein the invention was embodied in a mechanical combination; and it was held that, in a pioneer patent, such as that of Morley, the patentee, the special devices set forth by Morley were not necessary constituents

Dissenting Opinion: Shiras, Brewer, JJ.

of the claims; that his patent was to receive a liberal construction, in view of the fact that he was a pioneer in the construction of an automatic button sewing machine, and that his patent was not to be limited to the particular devices or instrumentalities described by him.

In that case extended and approving reference was made to the case of *Proctor v. Bennis*, 36 Ch. Div. 740, which was a case of an invention embodied in a mechanical contrivance, and the following language of Lord Justice Bowen was quoted:

"Now I think it goes to the root of this case to remember that this is, as was described by one of the counsel, really a pioneer invention, and it is by the light of that, as it seems to me, that we ought to consider the question whether there have been variations, or omissions, and additions, which prevent the machine which is complained of from being an infringement of the plaintiff's. . . . With regard to the additions and omissions, it is obvious that additions may be an improvement, and that omissions may be an improvement, but the mere fact that there is an addition, or the mere fact that there is an omission, does not enable you to take the substance of the plaintiff's patent. The question is not whether the addition is material, or whether the omission is material, but whether what has been taken is the substance and essence of the invention."

These were cases wherein the discovery or invention was made effective through machines or mechanical combinations, and wherein it was held that the merit of the process or method was not to be confined, in the case of a pioneer patent, to the mere form described in the specification as sufficient to make the invention practically operative.

Neilson's patent, Web. P. C. 275, was a noted case, in which the true distinction was drawn between a mere principle, as the subject of a patent, and a process by which a principle is applied to effect a new and useful result. The Court of Exchequer, in answering the objection that Neilson's patent was for a principle, said:

"It is very difficult to distinguish it from the specification

VOL. CLXX-37

Dissenting Opinion: Shiras, Brewer, JJ.

of a patent for a principle, and this at first created in the minds of some of the court much difficulty; but after full consideration, we think the plaintiff does not merely claim a principle, but a machine embodying a principle, and a very valuable one. We think the case must be considered as if the principle being well known, the plaintiff had first invented a mode of applying it by a mechanical apparatus to furnaces; and his invention consists in this — by interposing a receptacle for heated air between the blowing apparatus and the furnace. In this receptacle he directs the air to be heated by the application of heat externally to the receptacle, and thus he accomplishes the object of applying the blast, which was before of cold air, in a heated state to the furnace."

And when the case came before the House of Lords, Lord Campbell said:

"After the construction first put upon the patent by the learned judges of the Exchequer, . . . I think the patent must be taken to extend to all machines, of whatever construction, whereby the air is heated intermediately between the blowing apparatus and the blast furnace. That being so, the learned judge was perfectly justified in telling the jury that it was unnecessary for them to compare one apparatus with another, because, confessedly, that system of conduit pipes was a mode of heating air by an intermediate vessel between the blowing apparatus and the blast furnace, and, therefore, it was an infringement of the patent." Web. Pat. Cas. 715.

Very applicable to the present case is the doctrine of *Tilghman v. Procter*, 102 U. S. 707. It was there held, overruling the case of *Mitchell v. Tilghman*, 19 Wall. 287, that a patent may be validly granted for carrying a principle into effect; and if the patentee suggests and discovers not only the principle, but suggests and invents how it may be applied to a practical result by mechanical contrivances and apparatus, and shows that he is aware that no particular sort or modification of form of apparatus is essential to obtain benefit from the principle, then he may take his patent for the mode

Dissenting Opinion: Shiras, Brewer, JJ.

of carrying it into effect, and is not under the necessity of confining himself to one form of apparatus.

Having discussed the previous cases, particularly that of *Neilson* and of *O'Reilly v. Morse*, 15 How. 62, Mr. Justice Bradley said:

"Whoever discovers that a certain useful result will be produced in any art by the use of certain means is entitled to a patent for it, provided he specifies the means.' But everything turns on the force and meaning of the word 'means.' It is very certain that the means need not be a machine, or an apparatus; it may, as the court says, be a process. A machine is a thing. A process is an act, or a mode of acting. The one is visible to the eye — an object of perpetual observation. The other is a conception of the mind, seen only by its effects when being executed or performed. Either may be the means of producing a useful result. . . . Perhaps the process is susceptible of being applied in many modes and by the use of many forms of apparatus. The inventor is not bound to describe them all in order to secure to himself the exclusive right to the process, if he is really its inventor or discoverer. But he must describe some particular mode, or some apparatus, by which the process can be applied with at least some beneficial result, in order to show that it is capable of being exhibited and performed in actual experience."

The Telephone cases, 126 U. S. 1, 532, 533, 535, contain an apt illustration of these principles. Mr. Chief Justice Waite in discussing the case, said:

"In this art, or, what is the same thing under the patent law, this process, this way of transmitting speech, electricity, one of the forces of nature, is employed; but electricity, left to itself, will not do what is wanted. The art consists in so controlling the force as to make it accomplish the purpose. It had long been believed that if the vibrations of air caused by the voice in speaking could be reproduced at a distance by means of electricity, the speech itself would be reproduced and understood. How to do it was the question. Bell discovered that it could be done by gradually changing the intensity of a continuous electric current, so as to make it

Dissenting Opinion: Shiras, Brewer, JJ.

correspond exactly to the changes in the density of the air caused by the sound of the voice. This was his art. He then devised a way in which these changes of density could be made and speech actually transmitted. Thus his art was put in a condition for practical use. In doing this, both discovery and invention, in the popular sense of those terms, were involved; discovery in finding the art, and invention in devising the means of making it useful. For such discoveries and such inventions the law has given the discoverer and inventor the right to a patent—as discoverer, for the useful art, process, method of doing a thing he has found; and as inventor, for the means he has devised to make the discovery one of actual value. . . . The patent for the art does not necessarily involve a patent for the particular means employed for using it. Indeed, the mention of any means, in the specification or descriptive portion of the patent, is only necessary to show that the art can be used; for it is only useful arts—arts which may be used to advantage—that can be made the subject of a patent. The language of the statute is that ‘any person who has invented or discovered any new and useful art, machine, manufacture or composition of matter,’ may obtain a patent therefor. Rev. Stat. § 4886. Thus, an art—a process—which is useful, is as much the subject of a patent, as a machine, manufacture or composition of matter. . . . But it is insisted that the claim cannot be sustained, because when the patent was issued Bell had not in fact completed his discovery. While it is conceded that he was acting on the right principles, and had adopted the true theory, it is claimed that the discovery lacked that practical development which was necessary to make it patentable. In the language of counsel, ‘there was still work to be done, and work calling for the exercise of the utmost ingenuity, and calling for the very highest degree of practical invention.’ It is quite true that when Bell applied for his patent he had never actually transmitted telegraphically spoken words so that they could be distinctly heard and understood at the receiving end of his line, but in his specification he did describe, accurately and with admirable clearness, his process, that is to say, the

Dissenting Opinion: Shiras, Brewer, JJ.

exact electrical condition that must be created to accomplish his purpose, and he also described with sufficient precision to enable one of ordinary skill in such matters to make a form of apparatus which, if used in the way pointed out, would produce the required effect, receive the words, and carry them to and deliver them at the appointed place. The particular instrument which he had and which he used in his experiments did not, under the circumstances in which it was tried, reproduce the words spoken so that they could be clearly understood, but the proof is abundant and of the most convincing character that other instruments, carefully constructed and made exactly in accordance with the specification, without any additions whatever, have operated and will operate successfully. . . . The law does not require that a discoverer or inventor, in order to get a patent for a process, must have succeeded in bringing his art to the highest degree of perfection. It is enough if he describes his method with sufficient clearness and precision to enable those skilled in the matter to understand what the process is, and if he points out some practicable way of putting it into operation. . . . Surely a patent for such a discovery is not to be confined to the mere means he improvised to prove the reality of his conception."

The conclusion justified by the authorities is that whether you call Westinghouse's discovery, that "quick action" may be accomplished by the coöperation of the main pipe air and that from the car reservoir, a process, or a mode of operation, yet if he was the first to disclose it and to describe a mechanical means to give practical effect to the invention, he must be regarded as a pioneer inventor, and as entitled to protection against those who, availing themselves of the discovery, seek to justify themselves by pointing to mere differences in form in the mechanical devices used.

Much stress was laid in the argument on an alleged disclaimer by the patentee while the application was pending in the Patent Office, whereby it is said Westinghouse must be understood to have abandoned the second claim, or, at any rate, to have consented that that claim should be interpreted

Dissenting Opinion: Shiras, Brewer, JJ.

by the courts as if it contained an auxiliary valve as a material element in the claim.

There are cases, no doubt, in which it has been held that when a claimant has, under objection in the Patent Office, withdrawn certain claims, or has modified them by adding or striking out terms or phrases, and accepts a patent which does not grant the abandoned or unmodified claims, he cannot be heard to insist upon such a construction of the allowed claims as would cover what had been previously rejected. *Shepard v. Carrigan*, 116 U. S. 593; *Roemer v. Peddie*, 132 U. S. 313; *Corbin Cabinet Lock Co. v. Eagle Lock Co.*, 150 U. S. 38.

An examination of the cited cases, however, will disclose, as I think, that they turned upon matters of construction. In other words, were cases where it was questionable what the patent, as actually granted, meant. In such cases, as in other cases of ambiguity, it may be allowable to consult the application and file wrapper, and possibly written communications, which may throw light upon claims that are ambiguous or capable of different constructions.

But where the claims allowed are not uncertain or ambiguous, the courts should be slow to permit their construction of a patent, actually granted and delivered, to be affected or controlled by alleged interlocutions between the officers in the Patent Office and the claimant. No doubt, in proceedings to revoke or cancel a patent granted by inadvertence or by fraudulent representations, it would be competent to show what had taken place in the Patent Office pending the application. But when we consider that often the employés in the Patent Office are inexperienced persons, and that the mass of the business is so vast that it is impossible for the Commissioner or the Chief Examiner to review it, except in a perfunctory way, it can be readily seen how dangerous it would be to modify or invalidate a patent, clear and definite in its terms, by resorting to such uncertain sources of information.

However this may be, I do not perceive that the matters alleged in the present case are entitled to any weight in the construction of the patent. Even if the letter of the claimant's attorney, written on January 19, 1887, can be looked to

Dissenting Opinion: Shiras, Brewer, JJ.

as helping us to understand the meaning of a patent granted on March 29, 1887, it only appears to be an argument as to the meaning or legal effect of the language used in the claims, and does not amount to a withdrawal or modification of them.

Accordingly the second claim of the patent is before us for construction on its own terms, and, to avoid protracting this discussion, the opinion of Judge Morris in the Circuit Court is referred to and adopted as a sound construction of that claim. 66 Fed. Rep. 997. This claim is not, as I read it, open to the objection that it aims to patent a principle. It sets forth the discovery that by a coöperation of the air from the auxiliary reservoir and that from the main air-pipe, the action of the brakes is quickened and the air vented from the main air-pipe directly to the brake-cylinder.

But, even if the second claim must, as argued in the opinion of the court, be read, by reason of the letter of the claimant's attorney, as if it called for the auxiliary valve described in the first and fourth claims, and even if, when not so read, it can be regarded as void because simply for a function or principle, nevertheless the invention, as described in the other claims and specifications, is clearly set forth, and, under the evidence as to the state of the art, is entitled to be regarded as a pioneer. Regarding the second claim as a mere statement of the idea or invention and the other claims as describing a form or combination of mechanism which embodies the invention and renders it operative, all the requisites of the law are sufficiently complied with.

The only remaining question is that of the infringement, and that is readily disposed of. For it is conceded in the opinion of the majority of the court that, if the patent in suit is entitled to a broad construction as a pioneer, embodying a new mode of operation, not limited to the particular means described in the specification, then the defendant's device is an adoption of the idea or principle of the Westinghouse patent with a mechanical equivalent or substitute for the auxiliary valve.

Upon the whole I am of the opinion that the decree of the

Opinion of the Court.

Circuit Court of Appeals should be reversed and that the cause should be remanded with directions to restore the decree of the Circuit Court.

MR. JUSTICE GRAY and MR. JUSTICE MCKENNA also dissented from the opinion and from the decision of the court.
